**CUPANIA.** A large genus of trees or shrubs belonging to the *Sapindaceæ*, numbering upwards of fifty species, more or less frequent in all tropical countries, but found in greatest numbers in South America. They are distinguished from their near allies by having a dry capsular fruit, which bursts when ripe: those genera more immediately related to them having more or less fleshy fruits which do not burst when ripe. In all cases the leaves are pinnate, varying in length from six inches to two feet, and composed of few or many leaflets. The flowers are small, generally green or white, and arranged in terminal or axillary racemes or panicles; some of them contain stamens only, others both stamens and pistil. The calyx is five-parted; the petals five, with or without a little scale-like appendage; and surrounding the ovary is a fleshy ring, inside of which the stamens (eight to ten in number) are inserted. The ovary is crowned with a simple style, generally trifid at the top, and becomes when ripe a two or three-lobed capsule, woody or thin in texture, with two or three cells, each containing one seed; the latter in all the species are furnished with a large or small fleshy cup-shaped aril, which is frequently of a bright yellow colour, while the outer coating of the seed is generally black and polished. *C. edulis*, the Akee Tree, is sometimes called *Blighia sapida*: which see. The Tulp Wood of eastern tropical Australia is furnished by the *Cupania* or *Harpulia pendula*, a tree of lofty growth, with a stem varying from eighteen to twenty inches in diameter. The light coloured wood is interspersed with darker mahogany-coloured patches, and is susceptible of a high polish; it bears much resemblance to that of the Tamarind tree. A very curious circumstance has been noticed by Mr. Spruce in connection with the seeds of *C. cinerea*, a Peruvian tree with pinnate leaves, and wedge-shaped leaflets covered underneath with a white down. He says, 'The embryos fall out of the seeds, while the outer coating or husk of the seeds with their aril contained in the burst capsules still remain on the tree.' Lobolly-wood is the name given in Jamaica to the wood of a number of trees of this genus. [A. A. B.]

**CUP FLOWER.** *Scyophanthus elegans*.

**CUP GOLDBLOCKS.** *Trichomanes radicans*.

**CUPHEA.** A genus of *Zythrææ*, consisting of herbs or undershrubs, often viscid, natives of Tropical America, one species extending northwards as far as New York. The leaves are opposite, rarely

verticillate, entire; flowers solitary, on short often-curved stalks, and not unfrequently arranged in a racemose manner, purple, red or white; calyx tubular, inflated below, and gibbous or spurred at the base on the upper side, strongly nerved, the limb plaited and six-toothed, often with six smaller intermediate teeth, the whole coloured and often forming the most conspicuous part of the flower; petals six, rarely absent, unequal, the two uppermost generally much larger than the others: stamens about twelve, unequal, in two sets; ovary free, one or two-celled, few ovuled, with a slender style and two-lobed stigma. Capsule oblong, usually ruptured before the seeds are ripe, in which case the placentas with the seeds attached, protrude. [J. T. S.]

**CUPIDONE.** (Fr.) *Calananche cærulea*.

**CUP-PLANT.** An American name for *Silphium perfoliatum*.

**CUPRESSUS.** A genus of evergreen trees and shrubs, giving its name to the tribe *Cupressineæ*, of the family of conifers. Their foliage is not often to be distinguished from that of some species of juniper, consisting, as in that genus, of either small scale-like closely-appressed leaves, or of longer linear spreading ones, acute or acuminate, always opposite, and both forms occurring sometimes in different parts of the same tree or shrub. The fruit or cone is, however, very different from that of *Juniperus*, being much larger, with peltate woody scales opening to let out the seeds when ripe, and not at all succulent; and the seeds are winged. There are about ten species natives of the northern hemisphere, all extratropical or penetrating into the tropics only in mountain regions. They may be readily distributed into two sections, considered sometimes as distinct genera: *Cupressus* proper, with several seeds under each scale of the cone; and *Chamaecyparis*, with two seeds only to each scale. But the species themselves are very difficult to mark out, being distinguished rather by general habit than by any very positive botanical character.

*C. sempervirens* of Linnaeus, the common Cypress, is a native of Persia and the Levant, but so generally planted in the East that the precise limits of its indigenous area have not been well ascertained. It has two very remarkable forms. One, *C. fastigiata*, with erect closely-appressed branches, is the well-known tall Cypress, celebrated by Oriental poets for its elegant slender pyramidal form, and extensively planted in Southern Europe and Western Asia, especially in Mahomedan and Armenian burial grounds. It will there reach a height of above sixty feet, densely clothed with leafy compact branches to within four or five feet of its base, the trunk below the branches attaining twelve to fifteen feet in circumference. In our country, however, it is only in a few favoured spots that it will rise much above a bush of ten to fifteen feet, for it is of very slow growth,

and much liable to injury from wind and severe frost. The second variety, *C. hortensis*, or spreading Cypress, with all its

to the same species, were it not that it will frequently spring from the seed of *C. fastigiata*. In the south of Europe it readily grows to a tree, having much the form of a Cedar, but it is seldom planted in England.

*C. torulosa*, from the Himalaya, is one of the most elegant of modern introductions to our pinetums and shrubberies; the branches are erect or ascending, but less compact than in the common tall cypress and the colour is not so dark. It is hardy enough to bear well the climate of some parts of England, but in others suffers much in severe winters. *C. glauca*, another East Indian species, is much more tender, and will seldom outlive our winters without protection, but it is much planted in Portugal, and has thence acquired the name of *C. lusitanica*. *C. funebris*, from North China, with its long branches, said to droop like those of a Weeping Willow, promises to be a valuable addition to our hardy evergreens. To these must be added *C. macrocarpa* and *Gossypiana*, both Californian. The first a noble tree with the habit of *C. sempervirens*, the second of much smaller dimensions and with a less compact habit.

Of the section *Chamacyparis*, two species, *C. thuyoides* and *C. nukaensis* (*Thujopsis nukaensis* of our garden catalogues), from North America, and *C. squarrosa* (*Retinospora squarrosa* of our garden catalogues) from Japan, are to be met with in our plantations of conifers.

**CUPULE.** The cup or husk of the acorn, Spanish chesnut, &c.; a collection of bracts; a sort of involucre; a cup-like body found in such fungals as *Peziza*.

**CUPULA-SHAPED.** Slightly concave, with a nearly entire margin; as the calyx of *Citrus*, or the cup of an acorn.

**CURAGE.** (Fr.) *Polygonum Hydropiper*.

**CURANA WOOD.** The wood of *Icica aliesima*.

**CURATELLA.** A genus of small trees from Tropical America, belonging to *Dilleniaceae*, with alternate ovate rough leaves often with winged leaf stalks; flowers small, white, racemose; calyx of four unequal roundish sepals; petals four or five; stamens numerous; ovaries two, subglobose, united at the base, with sublobed styles; capsules leathery, hispid, one-celled, two-seeded; seeds with a membranous aril. The rough leaves of *C. americana* are used in Guiana for polishing. [J. T. E.]

**CURCAS.** A genus of *Euphorbiaceae* formed for the reception of the Physic-nut tree, *C. purgans*, or, as it was formerly called, *Jatropha Curcas*. It differs from *Jatropha* merely in having a bell-shaped corolla, while the latter has a corolla of

five distinct petals. It forms a large bush or sometimes a tree of twenty feet high, with soft spongy wood and smooth bark, and is indigenous in Tropical America, but is very generally found in all tropical countries, being cultivated for the purgative oil of the seeds. Its leaves, generally crowded at the apex of the branches, are smooth, entire, and heart-shaped, or more commonly three or five-lobed, and including the stalks, from six to eight inches in length. The small green flowers are supported on stalked cymes about the length of the leaves; the males occupy the extremities of the ramifications, and the females the forks. The former have a calyx of five leaves; a bell-shaped corolla with a five-lobed border; and a double staminate tube of ten stamens, the five inner longer than the others. The females have a similar calyx and corolla, and a three-lobed ovary crowned with a tripartite style, each branch forked at the apex.

Dr. Bennett in his *Gatherings of a Naturalist*, states that this tree 'contains a milky acid glutinous juice, which when dropped on white linen produces an indelible stain, at first of a light blue colour, but after being washed, changing to a permanent brown; it might therefore form a very excellent marking ink. The fruit is globular and fleshy, about the size of a filbert, and contains three seeds in distinct cells. When immature, it is of a green colour, and when ripe black. On removing the husk from the oblong seeds, a white kernel remains, which contains much oil, and has an agreeable almond-like taste. The seeds are collected by the natives of the Philippine Islands for the purpose of expressing the oil, which they use for

*Curcas purgans.*

burning in their lamps, as well as for medicinal purposes. The leaves are employed for fomentations, and the juice of the young buds or other parts of the tree as a beneficial application to the ulcerated surface of wounds. The seeds are employed

by the native doctors of the Philippine Islands, and are considered excellent and mild purgatives, in doses of from one to four seeds. The effects which result from an overdose are vomiting, purging, a burning sensation in the stomach and bowels, with a determination of blood to the head. The only antidote used by native practitioners is cold water; warm water they affirm would be injurious. The kernels are administered entire, or are pounded in a mortar with water, and after being strained given as a draught. Dr. Bennett has himself administered these seeds to Europeans, but has found their effects very irregular, and occasioning in all cases a burning sensation in the bowels, followed with nausea and vomiting.

The oil is said to be sometimes boiled with oxide of iron, and used by the Chinese as a varnish. It is of a light colour, and has been imported into England and used as a substitute for linseed oil, as well as for dressing cloth, burning in lamps, &c. Its qualities differ little from those of castor oil according to Dr. Christison, who says that twelve or fifteen drops of it are equal to an ounce of castor oil. The white milky juice in which the plant abounds is reported as having healing properties, and a decoction of the leaves is used in the Cape de Verd Islands to excite secretion of milk in women.

The only other species of the genus is *C. spathulata*, sometimes called *Mozinina spathulata*, a low bush found in Mexico, with stout succulent stems, having olive-coloured bark, and furnished with numerous warty excrescences from which the leaves and flowers arise. The former are small and spathulate, and the latter inconspicuous. [A. A. B.]

**CURCULIGO.** A genus of hypoxids found in extratropical South Africa, in tropical New Holland, and in India. They are herbs with grassy ribbed leaves, and short scapaceous spikes or fascicles of small inconspicuous flowers, which have a cylindrical tube adhering to the style, a regular spreading six-parted limb, and six stamens inserted in the mouth of the tube. The roots of *C. orchitoides* are bitter and aromatic, and are used medicinally in India; while those of *C. stans* are eaten in the Marianne Islands. [T. M.]

**CURCUMA.** A genus of *Zingiberaceae*, consisting of plants with perennial rootstocks and annual stems. The flowers are in spikes with concave bracts; they have a tubular three-toothed calyx; the tube of the corolla is dilated above, five of its lobes are equal, but the middle one of the inner row or the lip is larger and spreading; the filament is petaloid, three-lobed at the top, with a two-spurred anther on the middle lobe. The substance called Turmeric consists of the old tubers of *C. longa*, and perhaps some other species. The powder is used as a mild aromatic, and for other medicinal purposes in India. It enters into the composition of curry powder, and is used as a chemical test for the presence

of alkalies, which change its yellow colour to a reddish brown. The young colourless tubers of this plant furnish a sort of arrowroot; another species, however, *C. angustifolia*, furnishes East Indian arrowroot, which is prepared by bruising and powdering the tubers, and throwing the powder into water, which is frequently changed till the starch loses its originally bitter taste. *C. rubescens* and *C. leucorhiza* also furnish starch. *C. aromatica* and *C. Zedoaria* furnish Zedoary tubers, which are used by the natives of India as aromatic tonics, and as a perfume. Several species with yellow or reddish flowers are cultivated in hot-houses. [M. T. M.]

**CURL.** A formidable disease in potatoes, referrible to Chlorosis, in which the tubers produce deformed curled shoots of a pallid tint, which are never perfectly developed, and give rise to minute tubers. It is supposed to arise from the tubers being over-ripe. It is, however, a local disease, and is quite unknown in many districts. It must not be confounded with a curled state of the foliage, which arises from the presence of aphides. [M. J. B.]

**CURLS, BLUE.** An American name for *Trichostema*.

**CURRENT.** The common name for *Ribes*, but especially applied to *Ribes rubrum*, the red, and *R. agrum*, the black currant of the gardens. The currants of the shops are the dried berries of the Corinthian grape. — **AUSTRALIAN.** *Leucopogon Richei*. — **INDIAN.** An American name for *Symphoricarpos vulgaris*. — **NATIVE**, of New South Wales. *Leucopogon Richei*. — **NATIVE**, of Tasmania. A name applied to some species of *Coprosmas*.

**CURRENTWORTS.** A name given by Lindley to the *Grossularaceae*.

**CURRA-TOW.** *Ananassa Baganaria*.

**CURRORIA.** A genus of *Asclepiadaceae*, containing a single species from Western Tropical Africa. It has a five-parted calyx, with ovate-lanceolate sepals; the corolla tube is short and subglobose, the divisions of the limb are linear-lanceolate, and have a twisted aestivation; there are five linear scales in the throat of the corolla; the gynostegium is included; the pollen masses are slightly stalked and erect; and the stigma is short. [W. C.]

**CURRY-LEAF TREE.** *Berbera Konigii*.

**CURTISIA.** A genus of *Cornaceae*, the flowers of which have a four-parted calyx, four blunt petals, and four stamens alternating with them. The fruit is a small obovoid drupe, the hard part of which is four or five-celled. The name was given in honour of Mr. Curtis, a well-known English Botanist. *C. japonica* is a large and fine tree, a native of the Cape, with opposite shining broad or toothed leaves, of a rusty colour beneath; the flowers small and numerous. The natives of the region where it abounds employ it to form shafts for their javelins

or assagays; hence the common name Assagay-tree or Hassagay-wood. [G. D.]

**CURVATIVE.** When the margins are slightly turned up or down, without any sensible bending inwards.

**CURVE-RIBBED.** When the ribs of a leaf describe curves, and meet at the point; as in *Plantago lanceolata*.

**CURVINERVED, CURVE-VEINED.** The same as Convergent-nervose.

**CUSCO BARK.** A kind of cinchona bark.

**CUSCUTACEÆ.** (Dodders.) A natural order of corollifloral dicotyledons, belonging to Lindley's solanai alliance. The plants are included by some in a suborder of *Convolvulaceæ*. Leafless parasitic twining herbs, with flowers in dense clusters. Calyx inferior, four to five-parted; corolla persistent, four to five-cleft; scales alternating with the segments of the corolla, and adhering to them; stamens four to five; ovary two-celled, with two ovules in each cavity; styles two or wanting; fruit two-celled, either capsular or succulent; seeds with fleshy albumen; embryo spiral, filiform, having no cotyledons. The seeds germinate in the soil in the usual way, and afterwards become true parasites by attaching themselves to plants in their vicinity, and growing at their expense. Some of them destroy flax, clover, and other crops. Dodder, or scaldweed, is also the pest of beans and hops in some places. These parasites are found in the temperate regions of both hemispheres. They seem also to possess acrid and purgative qualities. The farmer requires to take care that dodder seeds are not mixed with those of his crops. They may be separated by careful sifting. There are upwards of fifty species included in four genera, of which *Cuscuta*, *Lepidanche*, and *Ephedra* are examples. [J. H. B.]

**CUSCUTA.** The Dodders, a genus of annual leafless parasitic plants, the stems of which consist of small wire-like tendrils that twine round the plant destined to be the foster parent, and into the texture of which they send out aerial roots at the points of contact, and through these imbibe the sap of the attacked plant. Our native flora contains two species: *C. europæa*, a plant which is described by Sir J. Smith as climbing 'two or more feet high upon thistles, oats, and any plants that are crowded together and will afford it nourishment'; and *C. Epithymum*, a smaller plant which grows on heath, thyme, &c. Besides these are now recognised *C. Epithymum*, the Flax Dodder, and *C. Trifolii*, the Clover Dodder, species, or probably varieties, which it would appear have been introduced with foreign seeds of their respective crops in the cultivation of which they are so gradually becoming most serious impediments. This is so much the case that we were induced to experiment largely on their mode of growth, with a view if possible to ob-

viate the evil. The extent of the mischief may be judged from the fact that it was reported in the *Agricultural Gazette* for 1888 that one grower of flax had separated no

*Cuscuta Epithymum.*

less than seventy bushels of Dodder seed from his flax crop. With some of this seed we carried out the following experiments:—

**Exp. 1.**—On sowing some seeds in a sancer with fine mould, the following appearances presented themselves. In four days, the radicle was extended. In five days the germ was elevated above the soil, bearing the seed-covering on its apex. In six days the young thread-like plant was as it were on the look-out for a foster parent, and by the eighth day, not finding a foster parent, it emerged from the soil and died. (See diagrams in *Agric. Gaz.* 1889, 746.) Thus, then, all the plants which germinated freely died within a few days, the thread-like germs gradually becoming elevated out of the soil, and then withering away. However, on planting young examples of flax, chickweed, tomato, and others among them, the later germinated seeds immediately directed their threads towards them, and commenced that parasitic mode of growth which was so fully shown in the next case.

**Exp. 2.**—A sancer was sown with a mixture of flax and Dodder. In a few days both germinated, and the Dodder threads were attracted to the stems of the young flax, their history and progress being as follows. In seven days the Dodder had just clasped a flax plant. In nine days, both Dodder and flax having grown, the elevation of the flax stem had lifted the firmly attached Dodder out of the soil. In eleven days the Dodder was throwing out buds for new shoots, and the lower unattached part was dying away. (See diagram already referred to.) This explains the method by which the Dodder first becomes attached to the plant upon which it grows. It makes one or two tight coils around its future support, and during the time these coils are progressing, the foster-parent is increasing in size, the compression of the former around the latter becomes tighter, thus causing the bark of the foster-parent

to be more delicate, while the parasite is preparing a series of aerial roots to penetrate it; it having done this, its position is firmly established, its own natural root dies quite away, and thenceforward its true parasitic growth is astonishingly rapid. Experiments 3 and 4 were repeated during the present summer, 1860, as follows:—

**Exp. 3.**—A plot of pure flax seed was sown in the botanical garden of the Cirencester Royal Agricultural College; this came up well, and afforded a good crop of fine flax.

**Exp. 4.**—A plot of flax seed and Dodder seed intermixed. In this the flax and Dodder came up simultaneously, and the thread-like germ of the latter soon twisted round the flax stems, and in time sent out branches in every direction, which in turn twined about fresh flax stems until the whole plot was borne down by the parasite, and both it and the crop went through the processes of flowering and seeding simultaneously: so that in harvesting the crop both would be gathered together, and of course, unless carefully separated, such flax seed would perpetuate the evil.

The same remark applies equally to the clover crops as to those of flax. If crops are to be free from the Dodder pests, the farmer must take care not to sow them with the seed for the crop, for it is now evident that this is their mode of propagation. *C. Trifolii* grows precisely in the same way, but the whole plant is smaller; the seeds on this account are not so readily detected, so that it is much on the increase. [J. B.]

**CUSPIDARIA.** A genus of *Bignoniaceæ*, natives of Brazil, containing several species, forming erect or subcandent glabrous shrubs. The leaves are opposite, petiolate, and simple or trifoliate, with petiolulate ovate acuminate and ciliate leaflets. The flowers are in terminal panicles. The cup-shaped calyx is cut into five long cuspidate teeth; the corolla tube is ventricose-campanulate, and the limb is five-lobed; one of the five stamens is sterile; the stigma is bilamellate, with long acute lobes; the four angles of the capsular fruit are produced into wings; the seeds also are winged. This genus is nearly related to *Bignonia* and *Lundia*. It is separated from the former by its ciliated anthers, from the latter by its awn-like sepals, and from both by its tetrapterous fruit. [W. C.]

This name has also been applied to a genus of ferns, which have since been called *Dicranoglossum*. [T. M.]

**CUSPIDATE.** Tapering gradually into a rigid point; also abruptly acuminate, as the leaflets of many *Rubi*.

**CUSSO.** The Abyssinian *Brayera anthelmintica*.

**CUSSONIA.** The name of a genus belonging to the order of Ivyworts, distinguished by the top-shaped calyx, which is adherent to the seed vessel, its border having from five to seven short teeth; the petals five to seven, adhering to a conical

disk on the upper part of the seed vessel; stamens five to seven, adherent to the petals; fruit almost round, with little juice, two to three-celled, one seed in each cell. The genus was named in honour of Cusson, a botanist of Montpellier. The species are shrubs, natives of the Cape or of New Zealand, having a soft stem, with leaves alternate, smooth, stalked, in three to seven large lobes: the flowers are greenish.

Two species have been known in our collections since the end of the last century; they are chiefly interesting on account of their peculiar aspect. *C. thyrsiflora* has the leaflets sessile, wedge-shaped, truncate, and three-toothed at the end. *C. spicata* has the leaflets wedge-shaped, acuminate, and serrated at the end, the flowers in spikes. *C. triptera* is by some considered to be a hybrid, having numerous leaflets, like those of *C. spicata*, but without stalks, as in *C. thyrsiflora*. [G. D.]

**CUSTARD-APPLE.** *Anona*. —, NORTH AMERICAN. *Asimina triloba*.

**CUTICLE.** The external homogeneous skin of a plant, consisting of a tough membrane overlying the epidermis. The word is also used for the skin of anything, including the epidermis.

**CUTIS.** The peridium of certain fungi.

**CUVY.** The name of the large common form of *Laminaria digitata* in Orkney, where the narrow plant with a smooth stem (*Laminaria flexilis*) is distinguished by the name of tangle. The situations in which the two plants grow, are, according to Mr. Clouston, very different: 'the Cuvy growing so far out in the sea that the highest limit can only be approached at the lowest stream tides, and from this it runs out into the ocean as far as the eye can penetrate, and probably much farther; while the tangle may be approached at ordinary tides, and forms a belt between the Cuvy and the beach. The general aspect also differs: the stems of the Cuvy stand up like a parcel of sticks, and the leaves wave from them like little flags; while the tangle lies prostrate on the rocks, the leaves mingle together and form a darker belt round the shore. Six or eight feet is reckoned a good length for a Cuvy, while tangles may be found from twelve to twenty feet.' [M. J. B.]

**CYANIUM.** A kind of follicle, resembling a legume.

**CYANANTHUS.** A genus of *Polemoniaceæ*, containing a few species of annual procumbent or erect herbs, found on lofty situations on the Himalayas. They have alternate entire or lobed leaves, and few solitary and generally terminal showy blue flowers. The calyx is inferior, tubular-campanulate, and five-cleft; the corolla is funnel-shaped, with a large five-cleft limb; the five stamens are inserted at the base of the corolla, alternate with its lobes, the anthers being adpressed to or connate with the

ovary. The ovary is free and five-celled, with many ovules in each cell, and bears a simple style, and a five-lobed stigma. The capsule is oblong-conical, dehiscent loculicidally. Some botanists, overlooking the superior ovary, have referred this genus to *Campanulaceae*, because of its five-celled ovary and five-lobed stigma, but in every other respect it appears more nearly connected with *Polemoniaceae*. [W. C.]

**CYANELLA.** A genus of herbs from the Cape of Good Hope, belonging to *Liliaceae*, and having lanceolate-elliptical or linear radical leaves sheathing at the base, and racemose blue or yellow flowers. Perianth coloured, six-parted; stamens six, with glabrous filaments: the lower perianth segments, the lowest stamen, and the style declinate; capsule three-celled, with numerous seeds. They are pretty greenhouse plants. [J. T. S.]

**CYANEUS, CYANÆUS, CYALINUS.** In composition *Cyano*. A clear bright blue.

**CYANOCHROUS.** Having a blue skin.

**CYANOPHYLLUM.** A genus of *Melastomaceae*, containing one or two undershrubs with large five-nerved leaves having a metallic lustre. The flowers are small, with five petals and ten stamens. *C. metallicum*, which grows at an altitude of 6,000 or 7,000 feet, has a blue metallic lustre on the under-surface of its leaves. *C. magnificum*, one of the grandest of what are now commonly cultivated in hothouses as ornamental-leaved plants, has its very large opposite leaves of a rich shaded green above, and purple beneath. They are from Tropical America. *C. assamicum*, a similar plant, is of eastern origin. [J. T. S.]

**CYANOSTEGIA.** A genus of *Verbenaceae*, found in West Australia, and composed of small upright bushes with narrow lance-shaped or linear entire leaves, often covered with a gummy substance. The blue flowers, in terminal branching racemes, are numerous and remarkable for their frill-like papery calyx, with a five-lobed border, which increases in size after the flowers have withered, and when mature is about half an inch in diameter. The somewhat irregular corollas are small and tubular. The great profusion of the blue flowers with their remarkably enlarged calyces of a paler colour, together with their neat bushy habit, would no doubt render them favourite greenhouse plants were they in cultivation. Three species are enumerated. [A. A. B.]

**CYANOTIS.** The generic name of plants belonging to the spiderwort order, characterised by having the calyx in three divisions joined into a tube at the lower part, and persistent; the three petals also joined to form a tube, but soon falling off; the style thickened upwards, ending in a point—the stigma—which is hollow and covered with hairs. The name of the genus is derived from the Greek words signifying 'blue' and 'ear,' in allusion to the colour

of the flowers. The species are showy plants, natives of Tropical Asia, annual or perennial, hairy or woolly, seldom naked, the stems trailing below, sometimes erect above. [G. D.]

**CYATHEA.** An extensive genus of arborescent ferns representative of the *Cyathea*. The genus belongs to that series or subgroup which has an indusium or involucre placed in the form of a cup beneath or so as to contain the spore-cases, the fructification being seated on the under surface of the fronds. The species are numerous, and rank amongst the most striking features of tropical scenery. They are most abundant in South America and in the West Indies, in India, the Eastern Islands, and the Pacific Islands; a few are met with in New Zealand and South Africa. In some the trunk is short, but in others it reaches a height of forty or fifty feet or even more, and is crowned with a magnificent head of fronds, which, in many cases, are of gigantic size, and are always large. The greater number have the fronds bipinnate, with the pinnae deeply pinnatifid; but in one, *C. Brunonia*, found in Malacca and Penang, they are pinnate, the fronds being two to three feet long, and the pinnae six or eight inches; and in another, *C. sinuata*, found in Ceylon, they are simple and lanceolate, with a sinuated margin. This latter has a slender trunk, about an inch in diameter, on which the elegant crown of simple wavy fronds is upborne. *C. medullaris*, a fine bipinnate or tripinnate species of New Zealand and the Pacific

*Cyathea medullaris*.

Isles, and known in gardens as a noble tree fern of comparatively hardy character, forms in its native country a common article of food with the natives. The part eaten is the soft pulpy medullary substance, which occupies the centre of the trunk, and which has some resemblance to sago. *C. dealbata*, another beautiful species of New Zealand, is said to be eaten in a similar way. This has a trunk of from

ten to fifteen feet high, crowned with a noble tuft of fronds, which are white beneath with a silvery powder. [T. M.]

**CYATHEINEÆ, CYATHEÆ.** The former is a principal sub-division or tribe of the polypodiaceous ferns, in which the receptacles are elevated and the sessile or subsessile spore-cases are oblique-laterally compressed, and burst horizontally, the ring or annulus being narrow, nearly complete, and more or less obliquely vertical. The latter is a section of this group, in which the sort have involucre or inferior indusia, the fructification being borne on the back of the fronds. [T. M.]

**CYATHIFORM.** The same as Cup-shaped.

**CYATHOCALYX.** A genus of *Anonaceæ*, characterised by having their petals hollow and constricted at the base, but expanding above into a flat blade; the stamens numerous; and the ovary solitary, embedded in a hollow receptacle, with several ovules attached to the line of union of the margins of the carpels. The genus includes a Cingalese tree, with flowers opposite to the smooth shining leaves. [M. T. M.]

**CYATHOCNEMIS.** A genus of begoniads, consisting of succulent Peruvian plants. The staminate and pistillate flowers have each two sepals: the anthers elongated with slightly united filaments; the style persistent, its branches furnished with a continuous papillose band, making two spiral turns; the seed-vessel margined with three equal wings. The peduncles at their dichotomous divisions are surrounded by a large cup-like bract. There is one known species, viz., *C. obliqua*, found on rocks in the Andes of Peru. It was formerly a *Begonia*. [J. H. B.]

**CYATHODES.** A genus of *Epacridaceæ*, consisting of fifteen species, natives not only of Australia, but, like very few other genera of this order, found also in New Zealand and the Pacific Islands. They are small branching woody heath-like shrubs, with small axillary white or yellow flowers. The pedicels are covered with imbricated bracts, which are gradually larger upwards, and appear to pass into the sepals; the corolla is funnel-shaped, with a naked or bearded limb, and a smooth tube; the stamens are included or exserted; the drupe is more or less fleshy, with a bony five to ten celled and five to ten-seeded nut, seated on a fleshy cup-shaped disc. [W. C.]

**CYATHOGLOTTIS.** An obscure genus of terrestrial orchids, with the ribbed foliage of an *Epidendrum*, to which genus it is probably more nearly allied than to *Sobralia*, with which it has been usually compared. Two Andine species are mentioned: one with white, the other with yellow flowers.

**CYATHUS.** The cup-like body which contains propagula, or the reproductive bodies of *Marchantia*.

**CYATHUS.** One of the genera to which the curious *Fungi* belong which are commonly named Bird's Nest Fossils. It is distinguished from *Nidularia* by the more complicated structure of the walls, and the stouter peduncle of the sporangia. We have two species generally distributed throughout England: *C. striatus*, which has a bright-brown shaggy cup, deeply grooved within, and *C. vernicosus*, which is mouse-grey, with the outer surface tomentose, and the inner polished. [M. J. B.]

**CYBELE.** *Peristylus*.

**CYBISTAX** (including *Yangua*). A genus of *Bignoniaceæ* confined to Peru, Bolivia, and Brazil, and easily distinguished from its allies by its lax plicate calyx, and broad pods traversed by twelve deep furrows on the surface. There seems to be only one species, *C. antisyphilitica* (*Yangua tinctoria* of Spruce), which forms a bush or small tree, and has when young duplicato-pinnate, when old digitate leaves. The bark of the younger branches is considered, in Brazil, one of the most powerful remedies against syphilitic swellings of a malignant character. The decoction is chiefly used, and also the bark dried and powdered and applied externally. In the Peruvian Andes, the tree is termed *Yangua* or *Atunyangua*, and the inhabitants dye the cotton cloths of their own manufacture a permanent blue by simply boiling them along with its leaves. About every three months all the leaves that can be got at are stripped off, and the trees seem not to suffer from being thus denuded; but they rarely put forth flowers till they grow beyond the reach of spoiling hands. The panicles are small, the calyx whitish, and the tubular corolla and the fruit of a greenish colour. In Brazil and Peru the plant is cultivated; it was also, at one time, an inmate of our gardens. [B. S.]

**CYCADACEÆ.** (*Cycads*). A natural order of achlamydeous dicotyledons belonging to the gymnospermous (naked-seeded) alliance. Small palm-like trees or shrubs, with unbranched stems, occasionally dividing into two, marked with leaf-scars, and having large rays in the wood along with punctated ligneous tubes. Leaves pinnate, and usually rolled up like a crozier while in bud. Flowers staminate or pistillate, and without any envelope (achlamydeous); staminate flowers in cones, the scales bearing one-celled anthers on their lower surface; pistillate flowers consisting only of ovules on the edge of altered leaves, or placed below, or at the base of scales. Seeds either hard, or with a soft spongy covering; embryo hanging by a long cord in a cavity of the albumen; cotyledons unequal. Natives chiefly of the tropical and temperate regions of America and Asia. They are found also in southern Africa, and in Australia. *Cycads* are mucilaginous and starchy. *Cycas revoluta*, a native of Japan, supplies a kind of starch which is used as sago; and a similar kind of false sago is supplied by *Cycas circinalis* in the Moluccas.

Caffre-bread is made from the starch of a Cape species of *Encephalartos*, many species of which genus exist in Australia. In the West Indies some species of *Zamia* yield a kind of arrowroot. Cycads occur in a fossil state after the coal epoch. There are seven known genera, and about fifty species. Examples: *Cycas*, *Dion*, *Encephalartos*, and *Bamia*. [J. H. B.]

**CYCAS.** A remarkable genus giving its name to the order *Cycadales*. It consists of trees of no great height, with cylindrical usually unbranched stems, terminated at the top by a crown of handsome deeply-cut pinnate leaves of thick texture. The male flowers grow in cones, consisting of scales bearing anthers on their under surface. The female plants bear in the centre of the crown of leaves surmounting the stem, a tuft of woolly pinnately-cleft leaves, in the notches of whose margins the naked or uncovered ovules are placed. The species are natives of the tropical regions of Australia, Polynesia, and Asia.

*C. circinalis* furnishes in Malabar a sort of sago, which is prepared from the seeds, which are dried and powdered; medicinal properties are attributed to the seeds, but these are of little importance. The plant is said to be singularly tenacious of life. The pith in the interior of the stem of *C. revoluta* abounds in starch, which is highly esteemed in Japan. A clear gum exudes from the trunks of these trees, which is said to be employed by the natives of India in promoting speedy supuration. These elegant species are great ornaments in our plant-houses. A fine group of them and of the allied genera may be seen at one end of the large palm-house at Kew. They are popularly but erroneously called Sago-palms, as they furnish none of the sago of commerce. See Plate 6, figs. b and d, the latter showing an old branched stem. [M. T. M.]

**CYCLADENIA.** A genus of apocynaceous plants, natives of California, and allied to the genus *Vinca*, but abundantly distinguished from it, says Mr. Benthani, by the cymose inflorescence, the funnel or bell-shaped corolla, and the ring-like disc at the base of the stamens, from which latter the genus derives its name. *C. humilis* is described as being a most beautiful plant, resembling *Villarsia pumila*. [M. T. M.]

**CYCLAMEN.** A well-marked genus of perennial herbs belonging to the *Primulaceae*. The species, which are not very numerous, are exceedingly beautiful when in flower. They have a roundish tuberous or fleshy rootstock, from the upper side of which proceed the leaves and flowers, sometimes directly from the top, sometimes from a short neck-like stem. The leaves are roundish or ovate with a deep basal sinus, sometimes angular at the margin, and often marbled with greyish-white. The flowers have a five-lobed calyx, and a monopetalous corolla, the tube of which is short, and the limb large and deeply five-lobed, the segments being turned back so as to

give the flowers the appearance of a shuttlecock. The corolla is five-valved; and after flowering the scape, in most of the species, coils up spirally with the seed-vessel in the centre, bending itself at the same time towards the ground, in which position the seeds are ripened. The name of the genus is derived from *κύκλος*, in allusion to the spiral peduncle, or according to others from the circular rootstock. The species are mostly South European, extending to North Africa, and Western Asia. The fleshy rootstocks, though acrid, are greedily sought after by swine, whence the names *Fene porcine* and *Pain de Porc*, from which the English name Sowbread is derived. *C. hederifolium*, an autumnal flowered species, with tubers frequently of large size, is found naturalised in some parts of England. [T. M.]

**CYCLANTHACEÆ.** A name sometimes given to the family of *Pandaceae*, of which the *Cyclanthaceae* are a tribe.

**CYCLANTHERA.** A Mexican climbing herb, belonging to the *Cucurbitaceae*. It has blind tendrils, and small green flowers. The female flowers are sessile, arising from the same point as the males. The latter are stalked, and their peculiarities have given rise to the name of the genus, and to the means of distinguishing it from its allies: the stamens, that is to say, are combined below into a short column which expands above into a round disc, bearing the anthers at its circumference. [M. T. M.]

**CYCLANTHUS.** A remarkable genus of Tropical American plants, referred to *Pandaceae*. From a contracted stem they throw up leaves, which are fan-shaped and cleft into two divisions. The flowers are unisexual, and arranged in spiral bands around the spadix, the bands consisting alternately of male and female flowers. The former have many stamens with four-celled anthers; the latter several ovaries, which become blended into a fleshy many-seeded fruit. The spadix is protected by a spathe which consists of four overlapping bracts. [M. T. M.]

**CYCLE.** A term employed in the theory of spiral leaf-arrangement to express a complete turn of the spire which is assumed to exist.

**CYCLICAL.** Rolled up circularly, as many embryos.

**CYCLOBOTHA.** A genus of Liliaceous plants, allied to *Oxiochorda*, from which they are distinguished by having all the divisions of the perianth bearded within, and furnished with a honey-pit in the centre, forming a hump or gibbosity on the outside. The species are found in Mexico and California, and are very singular and handsome objects. They have tunicated bulbs, and erect leafy stems, the leaves linear and acuminate, and the stems bearing at the top the nodding flowers, which are sometimes arranged in the form of an umbel, and have considerable general resemblance to those of certain species of *Frillaria*.

FOREST ON GUAM. ONE OF THE MARIANAS ISLANDS  
(After K. ...)

The perianth is bell-shaped or ventricose, with the three outer segments about half as large as the inner ones; and there are six stamens inserted in the base of the perianth, and a three-cornered ovary surmounted by three sessile stigmas. *C. lutea* grows about a foot high, and has oblong bulbs, long linear leek-like leaves, and two or three terminal yellow flowers, the divisions of which are scarcely connected at the base, the three exterior ones, which are smaller, greenish on the outer side, the three broader inner ones being bearded with purple hairs; the stem is bulbiferous in the leaf axils. *C. purpurea* is a more showy plant, growing two feet high, with the lower leaves elongately-linear, and the upper ones broader and more lanceolate; these also bear numerous little bulbs in their axils. The stem produces about three flowers, two from the point, and one from a side branch; these are large, with the sepals green marked with purple outside and yellow within, and the petaline segments brownish-purple outside, yellow within, and ciliated; the nectariferous pit is spade-shaped. [T. M.]

**CYCLODIUM.** A genus of polypodiaceous ferns belonging to the *Aspidiæ*. They are distinguished by having pinnate veins from a central costa, these producing convicently anastomosing venules, which form arcuate or angulate areoles. The sori, which are globose, are covered by peltate indusia. The species are thick-fronded robust pinnate ferns, with the fertile fronds more or less contracted, and sometimes so much so that the sori almost cover the surface. There are two or three closely allied species found in South America, and one in the Philippine Islands. [T. M.]

**CYCLOZYNE.** A genus of *Leguminosæ* found in Western Australia, the chief distinguishing character of which is found in the style, which is coiled inwards at the point, and much bearded. *C. canescens*, the only species known, is an astragalus-like bush with unequally pinnate leaves and leafy stipules; the leaflets (thirteen or fifteen in number) being small, oboval, smooth above, and clad underneath with white hairs. The white appanace these hairs give to the plant, together with the profusion of purple flowers, render it an attractive object. The flowers are disposed in erect racemes, and have a bell-shaped five-toothed calyx; a nearly round standard, with a green blotch at its base, two short wing petals, and a keel longer than the wings. The inflated oblong pods contain a number of seeds. [A. A. B.]

**CYCLOMYCES.** A curious genus of hymenomycetous *Fungi*, allied to *Polyporus*, in which the walls of the pores form gills concentric with the stem or with the border of the plicus. The species originally described was gathered in Mauritius, but another occurs in North America, and a third has been found in the Sikkim Himalaya. [M. J. B.]

**CYCLOPELTIS.** A name applied to two

pinnate aspidiaceous ferns, with peltate indusia and free veins, now referred to *Polystichum*. [T. M.]

**CYCLOPHORUS.** A name given by Desvauz to a group of polypodiaceous ferns, subsequently called *Niphobolus* by Kaulfuss, on the ground that Desvauz's name was in use among conchologists. *Niphobolus* has been generally adopted. [T. M.]

**CYCLOPIA.** A genus of dark-coloured South African bushes of the leguminous order, belonging to that group of the family in which the filaments of the stamens are quite free. They may be recognised from their allies by having a circular depression at the base of the calyx, round the pedicel. The leaves are sessile and made up of three generally linear smooth, or pubescent leaflets, which often have their margins rolled backwards. Their bright yellow broom-like flowers are generally produced in great profusion from the axils of the upper leaves, and have their stalks always furnished with two boat-shaped bracts. The pods are oblong, compressed, and contain a number of seeds. *C. genistoides*, a plant sometimes seen in greenhouses, has smooth linear leaflets strongly recurved at the margin, and pretty yellow broom-like flowers. The leaflets of this plant are used at the Cape in infusion or decoction for promoting expectoration in chronic catarrh and consumption. It is called Bush Tea, and has an agreeable tealike smell, with a sweet astringent taste. [A. A. B.]

**CYCLOSIS.** A supposed motion of fluids, occurring in the kind of tissue called cinchynus.

**CYCNOCHES.** A singular genus of orchids, with the habit of *Catantem*. The name, which signifies Swan-neck, was suggested by the long curved column which in the original species rose gracefully from a broad convex lip. The character of the column is proper to all the species, but the lip varies from a broad solid oval plate to a stalked disk whose margin is broken up into numerous glandular rays. And, what is most strange, the same stalk bears flowers of both kinds, with others intermediate between the two. Here, therefore, we have a repetition of the singular variations already described in *Catantem*. Upon this the Editor of *Paxton's Flower Garden* makes the following remarks: 'In Mr. Bateman's magnificent work we are told how the long-spiked small purple-flowered *C. Egertonianum* is only the short-spiked large green-flowered *C. ventricosum*; how the same plant at one time bears one sort of flowers, and at another time another sort; and we have ourselves shown how the same plant, nay the same spike, is sometimes both the one, the other, and neither. *C. Egertonianum* is then a 'sport,' as gardeners say, of *C. ventricosum*. But what, again, is *C. ventricosum*? Who knows that it is not another 'sport' of *C. Loddigesii*, which has indeed been caught in the very act of showing a false countenance, something wonderfully suspicious, all things

considered, and justifying the idea that it is itself a mere Janus, whose face is green and short on one side, and spotted and long on the other? Then, if such apparently honest species as *C. Egertonianum*, *ventricosum*, and *Loddigesii* are but counterfeit, what warrant have we for regarding the other so-called species as not being further examples of plants in masquerade? For ourselves we cannot answer the question: nor should we be astonished at finding some day a *Cynoches* no longer a *Cynoches*, but something else: perhaps a *Cataselum*. If one could accept the doctrine of the author of the *Vestiges*, it might be said that in this place we have found plants actually undergoing the changes which he assumes to be in progress throughout nature, and that they are thus subject to the most startling conditions only because their new forms have not yet acquired stability.

The principal species of this curious genus are *C. Loddigesii*, *ventricosum*, and *chlorochiton*, which have a sessile perfectly entire fleshy lip; and *C. pentadactylon*, *aureum*, *maculatum*, and *Egertonianum*, with a stalked flat lip, whose edges are broken up into numerous finger-like rays. These plants are all from Tropical America, and chiefly from the central states. See LUDDEMANNIA.

CYDONIA. A genus of the pomaceous division of the *Rosaceæ*, allied to *Pyrus*, from which it is distinguished by its leafy calyx-lobes, and the many-seeded cells of its fruit, those of *Pyrus* being dispermous. It comprises a few species, one of which is the well-known Quince; and another, *C. japonica*, one of the most ornamental deciduous shrubs in our gardens. The latter reaches some five or six feet in height, and is clothed in summer with oval crenately serrated leaves having kidney-shaped serrated stipules, and in spring with a multitude of glowing red flowers, to which it owes its beauty. [T. M.]

The common Quince tree is called *C. vulgaris*. The name of *Cydonia* was given to this by the ancients from its growing abundantly near Cydon, in the isle of Crete, now Candia. It is stated by some authors to have been introduced from Greece to Italy; but this can only refer to a particular variety, for Pliny in his fifteenth book says, 'There are many kinds of this fruit in Italy, some growing wild in the hedges, others so large that they weigh the boughs down to the ground.' Sir Joseph Banks (*Trans. Hort. Soc.* i. 153), referring to Martial (xiii. 24), states that the Romans had three sorts of Quinces, one of which was called *Chrysomela* from its yellow colour; they boiled them with honey as we make marmalade. According to the best modern botanists, the species grows spontaneously on the hills and in the woods of Italy, in the south of France, in Spain, Sicily, Sardinia, Algeria, Constantinople, the Crimea, and in the south of the Caucasus; it also grows abundantly on the banks of the Danube. It is found in Cashmere, and even in the north of India, according

to Drs. Roxburgh and Royle. De Candolle thinks its native country extends perhaps as far as Hindoo-Cooch; but it is not cultivated in the north of China. In Imiretta, a region in the interior of Mingreila, a variety is said to have been found with fruit as big as the head of a child. It appears from the above that the Quince is indigenous over a great extent of Europe and Asia, and that it is likewise found in the north of Africa. Phillips says in his *Historical and Botanical Account of Fruits known in Great Britain*, 'The learned Goriopius maintains that Quinces were the golden apples of the Hesperides, and not oranges, as some commentators pretend. In support of his argument, he states that it was a fruit much revered by the ancients, and he assures us that there has been discovered at Rome a statue of Hercules that held in its hand three Quinces; this,' he says, 'agrees with the fable which states that Hercules stole the golden apples from the gardens of the Hesperides.' Galezio, in his treatise on the Orange, has shown that the orange tree was unknown to the Greeks, and that it did not naturally grow in those parts where the gardens of the Hesperides were placed by them. The Quince tree, according to the *Hortus Kewensis*, was introduced into this country in 1573; but Gerard, who was alive at that date, says it was often planted in hedges and fences to gardens in his time, and from this it may be concluded the tree was common long before the period above mentioned.

The Quince is a hardy deciduous tree, fifteen to twenty feet high, with numerous crooked branches, forming a bushy spreading head; the leaves are roundish or ovate. The flower-buds push early in spring, and elongate into a branch, with five or six leaves, and at the extremity a single flower, white or pale red and of large size, is produced as late as May or June. The fruit is large, roundish, turbinate, pear-shaped, or irregularly oval, according to the variety. On approaching maturity it assumes a fine golden yellow colour, giving the tree a very ornamental appearance. The Portugal Quince is considered the best, but it does not bear so abundantly as the more common apple and pear-shaped varieties. All the varieties have a strong odour, with an austere flavour, so that they are unfit for eating raw; but the fruit is much esteemed along with apples in pies and tarts, and in confectionary it forms an excellent marmalade and syrup. Indeed, the name of marmalade is said to be derived from Marmelo, the Portuguese name of the Quince. The plants are much used as stocks for pear trees, especially those intended to be kept dwarf. [R. T.]

CYLINDRENCHYMA. Cylindrical cellular tissue, such as that of *Conserve*, of many hairs, &c.

CYLINDROLOBUS. *Eria*.

CYLISTA. A genus of *Leguminosæ*, found in the Bomhay districts of India,

and only represented by a single species, *C. scariosa*, which is a perennial twiner growing among bushes, with ternate leaves, having oval, pointed, and entire leaflets with short white pubescence. The yellow flowers, borne on erect bracted racemes, are remarkable for their large papery calyx, which is much more conspicuous than the corollas, and is deeply four-cleft; the upper segment being two-lobed, the lateral ones much smaller, and the lowest very large, all of them beautifully veined. The little oval one-seeded pod is completely enveloped in the peculiar calyx, which affords the most marked character in the genus. [A. A. B.]

**CYMBALAIRE.** (Fr.) *Linaria Cymbalaria*.

**CYMBELLÆ.** Reproductive locomotive bodies, of an elliptical form, found in some algae.

**CYMBIDIUM.** A name given by Swartz to a large group of tropical orchids, growing in the ground, with simple fleshy hairy roots, throwing up tufts of sword-shaped leaves, and producing radical spikes of flowers, which are erect or pendulous, many-flowered or few-flowered, and conspicuous for their beauty, or quite inconspicuous. All have a pair of curved ridges on the lower part of the lip: an essential character. Many plants in which this character is absent, and which have been erroneously referred to the genus, are now eliminated; nevertheless some twenty or thirty legitimate species remain. Of them the most important are *C. sinense*, a strong Chinese species with erect spikes of brown flowers emitting the most delicious fragrance; *C. giganteum*, an Indian plant with racemes of very large brown tessellated flowers; *C. eburneum* from India, with large radical ivory-white flowers smelling like lilacs; and *C. elegans*, also Indian, with great massive pendulous spikes of yellowish flowers. There are also many yellow Cape species not yet known in cultivation.

**CYMBIFORM.** Having the figure of a boat in miniature; that is to say, concave, tapering to each end, with a keel externally, as the glumes of *Phalaris canariensis*.

**CYMBOCARPA.** A genus of *Burmanniaceæ*, consisting of a single slender leafless annual, closely allied to *Dictyostegia*.

**CYME.** A kind of inflorescence, produced by the rays of an umbel forming one terminal flower, and then producing secondary pedicels from below it, in the centrifugal manner, as in the *laurustinus*.

**CYMINOSMA.** Small trees with opposite or alternate entire dotted leaves on a jointed stalk. They are of uncertain position, but are generally placed in *Rutaceæ*, and by some authorities are included in *Acronychia*. The flowers are white or greenish, in axillary or terminal corymbs, and have a four-parted calyx and corolla;

eight stamens with flattened filaments, four longer than the others; an ovary with four two-ovuled cells, placed on a fleshy disc; a short style; and a berry-like fruit. The species are natives of China, the East Indies, and Australia. [M. T. M.]

**CYMODOCEA.** A genus of *Zosteraceæ*, containing a diocious plant resembling *Zostera*, and found in the Mediterranean Sea. It has creeping branched rhizomes, and ribbon-like leaves faintly serrulated towards the apex: the flowers have no perianth, and consist of a pair of male flowers each reduced to a single two-celled stamen, or a pair of female flowers reduced to a single ovary, with a short style and two stigmas, which are long and thread-like. The fruit is produced in pairs. [J. T. S.]

**CYNANCHUM.** A genus of South European and Mediterranean herbs, belonging to the order *Asclepiadaceæ*, and characterized by its wheel-shaped corolla, and by the coronet of the stamens being tubular, with from five to ten divisions at its upper margin, and with five inner segments exterior to, and parallel with, the anthers. The fruit consists of two cylindrical follicles. The Argheï, the leaves of which are used to adulterate Alexandrian Senna, was formerly considered to belong to this genus, but is now included in *Solenostemma*: see also *Vincetoxicum*. [M. T. M.]

**CYNARA.** A genus of *Compositæ*, of which many of the species are prickly troublesome weeds, some are handsome, but scarcely any are useful besides the two familiarly known as the Artichoke and Cardoon.

The Cardoon or Chardon, *C. Cardunculus*, very much resembles the artichoke. It is a hardy perennial, a native of the south of Europe and the northern parts of Africa. The earliest writer on gardening who has noticed it is Parkinson, who calls it *Cardus osculentus* in his *Paradise Terrestris*, published in 1629. Its introduction into this country is stated to have been in 1668, and according to Dr. Neill, it was even cultivated in Holyrood Palace Garden so early as 1683; but it has never been considered a vegetable of much excellence, and at the present day it is only to be met with in a few of our best gardens. On the continent, however, the Cardoon is regarded as a wholesome esculent, which in the hands of a skilful cook forms an excellent dish. The parts which are used are the stalks of the inner leaves, rendered white, crisp, and tender by blanching. These stalks are either stewed, or form an ingredient in soups and salads during autumn and winter. When permitted to flower, the plant has a fine appearance, and attains a greater height than the artichoke. The flowers have also the property of coagulating milk, for which purpose they are frequently used by the French, after being gathered and dried in the shade.

The Artichoke, *C. Scolymus*, is a hardy perennial, a native of Barbary and the south of Europe. Although it is mentioned

by Pliny as being a vegetable that was much esteemed by the Romans, it does not appear to have been known in this country until introduced from Italy in 1548. The plant has some resemblance to a large thistle. The leaves are numerous, ample, pinnatifid, somewhat spiny, from three to four feet long, and covered with an ash-coloured cottony down. The flower stems grow erect, and attain the height of from four to six feet. They are each terminated by a large globular head of imbricated oval apiny scales of a purplish-green colour, which envelope a mass of flowers in the centre. These flower-heads in an immature state contain the parts that are eatable; which comprise the fleshy receptacle usually called the 'bottom,' freed from the bristles and seed-down, commonly called the 'choke,' and the thick lower part of the imbricated scales or leaves of the involucre. Although Artichokes are a common vegetable, they are not so much in request with us as on the continent, where by various modes of cooking they are made to form favourite dishes. In France, the bottoms are often fried in paste, and enter largely into ragouts. They are occasionally used for pickling, but for this purpose the smaller heads which are formed on the lateral shoots that spring in succession from the main stem, are generally preferred when about the size of a large egg. The Chard of Artichokes, or the tender central leaf-stalk blanched, is by some considered to be equal to the cardoon. The flowers are very handsome, and are stated to possess the property of coagulating milk. [W. B. B.]

**CYNAROCEPHALÆ.** The artichoke-headed composites, a suborder of the natural order *Compositæ* or *Asteraceæ*, having numerous flowers collected in a common receptacle, and surrounded by a series of leaves or scales so as to form a compact head. The flowers are all tubular, and either have stamens and pistils, or those of the circumference (the ray) are abortive; the style is swollen below the stigma. Among the plants of this suborder are the artichoke, the cardoon, the burdock, the safflower, and thistles. They are usually bitter and tonic; some are esculent. See *COMPOSITÆ*. [J. H. B.]

**CYNARRHODON.** Such a fruit as that of the rose, in which many bony achenia are enclosed in a fleshy hollow enlargement of the apex of the flower-stalk.

**CYNOCOTONUM.** A genus of *Asclepiadaceæ*, containing more than thirty species of perennial herbaceous plants or twining shrubs, natives of Africa, India, and tropical America. They have cordate leaves, and lateral peduncles springing from between the petioles, and bearing many-flowered umbels. The calyx and corolla are five-parted; the staminal corona is tubular and simple, with five or ten lobes, and without any appendages in the interior; the gynostegium short; the anthers surmounted by membranaceous append-

ages; and the projecting stigma is bilobed or with a bifid linear apex. [W. C.]

**CYNODON.** A genus of grasses belonging to the tribe *Chlorideæ*, distinguished chiefly by the spikes of inflorescence being in short spreading finger-like heads. The spikelets one-flowered, awnless; the glumes nearly equal, spreading; pales equal; stamens three; and styles three. Fourteen species are described, only one of which is a native of Britain, *C. Dactylon*, which inhabits the southern coasts of England. The creeping roots of this and some other grasses are said to possess some of the medicinal properties of sarsaparilla. [D. M.]

**CYNOGLOSSUM.** Houndstongue. A genus of *Boraginaceæ*, consisting of herbs from the temperate zones, especially of the northern hemisphere. Leaves often covered with silky-white hairs; flowers in scorpioid racemes, often bractless, dull-red or blue; calyx five-parted; corolla salver-shaped with the throat closed by five obtuse scales, and the limb five-lobed; stamens five, included; nuts four, muricately depressed externally. Two species occur in Britain, *C. officinale*, with leaves covered with soft white hairs, dull-red flowers, and strongly-margined nuts; and *C. montanum*, a much more local plant, with green roughish leaves without soft hairs, blue-veined flowers, and nuts without a prominent margin. [J. T. S.]

**CYNOMORIUM.** One of the genera of the singular family *Balanophoraceæ*. It is represented by a fleshy red herbaceous plant, about a foot in height, covered with scales, the flowers of which are unisexual, the males and females mixed in the same heads, and surrounded by numerous scales; occasionally the flowers are hermaphrodite. The perianth in either case consists of six divisions.

*C. coccineum*, the fungus *melitensis* of old writers, was formerly valued as a styptic and astringent. The plant is not confined to Malta, but extends also to the Levant, Northern Africa, and the Canary Islands, in which, according to Mr. Webb, it is esteemed good to eat. It was formerly used to procure abortion in Malta, and was so highly valued as a remedy for dysentery that the place where it grew was guarded with the utmost vigilance; and even up to a recent date the plant was gathered, and its growth secured by a person specially appointed to the office by the English Government. [M. T. M.]

**CYNORCHIS.** A Mascaren genus of terrestrial orchids, differing from *Habenaria* in little except the lip being connate with the face of the column. The species have testiculate roots, like the orchids of Europe. One, *C. fastigiata*, has been in cultivation (see *Bot. Register*, t. 1966). Blume's genus, *Mitostigma*, is a synonym.

**CYNOSURUS.** A genus of grasses belonging to the tribe *Festuceæ*, and distinguished chiefly by the inflorescence being

in crowded close thyrsoid panicles, with flowers pointing to one side; glumes nearly equal, scarious, and strongly keeled, two or more-flowered; each spikelet with a pectinated bract at its base. The genus comprises five species, only one of which, the Dog's Tail grass, *C. cristatus*, is truly a native of Britain. This is considered an excellent species for permanent sheep-pasture. The roots penetrate deep into the earth, which enables the plant to withstand droughts better than many of the other pasture-grasses; hence it may often be seen looking quite fresh when they are partially withered up. *C. echinatus* is an annual species, which is occasionally cultivated in British collections of grasses. It is a southern plant, but extends as far north as the Channel Islands. [D. M.]

**CYPELLA.** A genus of beautiful *Iridaceæ*, consisting of a single species, *C. Herberti*. The perianth is six-parted, concave at the base, the outer segments larger and spreading, the inner ones small convolute and reflexed at top. There are three erect stamens, united at the base of the filaments; a slender style; and a three-lobed stigma with trifid segments, which are appendiculate on both sides at the base. The chief distinction of the genus consists in its spreading not reflexed sepalline segments, and in their being deeply indented or hollowed out, as it were, at the base, so as to form a kind of bowl or cup. *C. Herberti* is a very slender plant, with fleshy corms, long lanceolate acute plaited glaucous leaves, and a slender stem 1½ to 2 feet high, branched at top and producing in succession many flowers which last for several days, unlike those of some allied plants which are very fugacious. The flowers are bright orange yellow, the three outer segments with a central dark purple stripe, the three inner whitish in the centre, spotted with purple. It is a native of Buenos Ayres. [T. M.]

**CYPERACEÆ.** (*Cyperoides*, *Sedges*.) A natural order of glume-bearing monocotyledons belonging to Lindley's glumal alliance. Grass-like tufted plants, having solid, usually jointed, and frequently angular stems; leaves with their sheaths entire (not split, as in grasses); and flowers either perfect or incomplete (staminate and pistillate), each borne on a solitary bract or scale, and all united in an imbricated manner so as to form a spike. In the pistillate flowers there is often a membranaceous covering within the scale. Stamens hypogynous, varying from one to twelve, usually three; anthers attached at their base to the filament. Ovary superior, often surrounded at the base by bristles; ovule one; style two to three-cleft. Fruit a crustaceous or bony achene; embryo lens-shaped, and lying at the base of fleshy or mealy albumen. The plants are generally distributed over the world, and abound in moist situations. Some of the sedges are demulcent, others are bitter and astringent. Some by means of their creeping underground stems bind together the loose

sands of the sea-shore. Their cellular tissue is sometimes used for paper. The underground stems of several species of *Cyperus* are used as food. Carices abound in moist temperate and cold regions. *Carex arenaria* is one of the sandy-shore plants; its underground stems are used for sarsaparilla. The species of *Eriophorum*, or cotton grass, have long white silky hairs surrounding the fruit. *Papyrus antiquorum* appears to be one of the plants called bulrush in scripture. It formerly grew abundantly at the mouth of the Nile, which was hence called by Ovid papyriferous, but it is now gone. The cellular tissue of its stems was used in place of paper. *Scirpus lacustris*, the bulrush, is used for making mats, baskets, and the bottoms of chairs. In South America it is used for making balsas or boats; a similar use is referred to in Isaiah (xviii. 1, 2). There are 120 known genera, and upwards of 2,000 species. The genera *Carex*, *Cladium*, *Scirpus*, *Eleocharis*, *Eriophorum*, *Cyperus*, and *Papyrus* afford examples. A plant of this family is shown in Plate 10, fig. a. [J. H. B.]

**CYPERORCHIS.** A name proposed by Blume for the *Cymbidium elegans* of Lindley, on account of its having a prominent stigma and pyriform pollen masses.

**CYPERUS.** A genus of plants giving its name to the sedge family, *Cyperaceæ*. It is distinguished chiefly by the stem being triangular, and leafy at the base; spikelets distichous, imbricated, in clusters or heads, with a leaf-like involucre under them; glumes several in each spikelet, with one flower in each glume; seed without bristles. According to Steudel's untrustworthy *Synopsis*, the genus contains 673 species, widely distributed over the warmer parts of the earth, and gradually disappearing as the extremes of north and south are reached. Two species only are natives of Britain, both of which are rare and not found out of England. Dr. Lindley states that the roots of these plants are succulent, and filled with an agreeable and nutritive mucilage. The English species, *C. longus*, contains also a bitter principle, which gives its roots a tonic and stomachic quality. The tubers of *C. hexastachys* are said to be successfully used by Hindoo practitioners in cases of cholera, who call the plant Mootha. Those of *C. pectenatus*, or Nagur Mootha, are, when dried and pulverised, used by the Indian ladies for scouring and perfuming their hair. The root of *C. odoratus* has a warm aromatic taste, and is given in India in infusions as a stomachic. The roots of some of the species are also used as an article of diet. *C. esculentus* yields tubers which are called by the French *Souchet comestible* or *Amande de terre*, and are used as food in the south of Europe. According to Dr. Royle, they have been proposed as a substitute for coffee and cocoa when roasted. The tubers of another species, *C. bulbosus*, are said to taste like potatoes when roasted, and would be valuable for food only they are

so small. Some are also useful for textile purposes, *C. testilis* being employed in making ropes and mats for covering the floors of houses; others are valuable for covering the sand and loose soil on the borders of rivers and streams; thus, *C. mundatus* helps to bind the banks of the Ganges, protecting them from the rapidity of the stream, and the force of the tides. (See *Lindley, Veg. King.* 118.) [D. M.]

#### CYPHEL. *Cherleria sedoides*.

CYPHELIA. Collections of gonidia in the form of cups; a term only used in speaking of lichens.

CYPHELLÆ. Palo wart-like spots, found on the under-surface of the thallus of some lichens.

CYPHIA. A genus of three or four South African species, intermediate, as it were, between *Campanulæ* and *Lobelieæ*, and therefore, when these two tribes are considered as independent families, *Cyphia* is raised to the same rank under the name of *Cyphiaceæ*. The species are all slender herbaceous twiners, with small nearly regular bell-shaped flowers, and united anthers. They possess no peculiar interest, except that the Hottentots are said to eat the tuberous roots of at least one species.

CYPHOCARPUS. A genus of *Campanulaceæ*, containing a rigid scabrous pilose herb from Chili, with erect stems, and oblong spinosely dentate radical leaves. Bracts three together, spinosely dentate; calyx tubular-curved, contracted at the mouth, with a five-parted limb, having spinous-toothed segments; corolla very irregular, two-lipped; capsule one-celled, resembling a follicle. [J. T. S.]

CYPHONEMA. A genus of cyrtanthiform *Amaryllidaceæ*. The only species, *C. Loddigesianum*, produces scapes with about two erect flowers, which measure an inch and three quarters, and are whitish, striped with green. The perianth has a straight slender cylindrical tube, campanulate above, with a regular reflexed limb. The plant had been supposed to have been imported from Valparaiso, but Dr. Herbert, by whom it was described, suspected it to be South African. [T. M.]

CYPRESS. (Fr.) *Cupressus sempervirens*. —, CHAUVÉ or DE LA LOUISIANE. *Taxodium distichum*.

CYPRESS. The common name for *Cupressus*, especially applied to *C. sempervirens*. —, BALD. An American name for *Taxodium*. —, BROOM. *Kochia scoparia*. —, DECIDUOUS. *Taxodium distichum*. —, GROUND. *Santolina Chamæcyparissus*. —, SUMMER. *Kochia scoparia*.

CYPRESS KNEE. See *Exostosis*.

CYPRIPEDIUM. In the north of England the eye of the botanist has been now and then delighted by the discovery of one of the rarest of native plants, *C. Calceolus*,

once called *Calceolus Marianus* or the Slipper of our Lady. It has a branching fibrous root; single stems, a foot or more high, bearing three or four broad ovate rather downy ribbed leaves, clasping the stem at the base, and one or two large flowers. These consist of two lanceolate brown purple sepals, and a pair of somewhat narrow wavy petals crossing each other at right angles (decussating); from the midst of these projects a great yellow pouch or bag, within which lurks the column, for the plant is an orchid. From other orchids it differs, however, in having two lateral anthers instead of one that is dorsal, the latter being represented by a great broad angular plate, in front of which projects a stalked three-lobed stigma. This curious deviation from the ordinary state of an orchid flower is characteristic of the genus *Cypripedium* (that is to say, shoe of Venus). Great numbers of species of the same genus occur in both the Old and New World, in the ice-bound woods of Canada and Siberia, the warm glades of Mexico and Nepal, and in the torrid regions of Central India and Continental (not Insular) America. Some of them have yellow flowers, and they are the most frequent; others are white and pink; many are more or less purple; and one, *C. guttatum*, a Russian plant, is richly bloodstained. Two principal forms are to be distinguished, one having thin ribbed leaves, and the other narrow carinate veinless ones. The latter, which are all from warm countries, are easily cultivated, and are common in gardens under the names of *C. venustum*, *insigne*, *purpuratum*, *Lovet*, *Dayanum*, *Fairieanum*, *villosum*, &c. The others, though often introduced, live for only a short time and disappear. In addition to these, another race, exclusively found in Tropical America, distinguished by having a three-celled ovary, might be added. We prefer, however, to notice it under the name of *Selenipedium*. The curious *Cypripedium caudatum* belongs to that race.

CYPSELA. The dry one-celled one-seeded inferior fruit of composites.

CYPSেলা. A genus of *Tetragoniaceæ*, consisting of a small fleshy annual herb, resembling *Montia*, from St. Domingo. Stems prostrate, with small oval or obovate stalked alternate or opposite leaves, and fringed stipules; flowers small, solitary, shortly stalked, with a free five-parted calyx and no corolla, the two inner segments of the calyx broader and membranous; stamens one to three; ovary one-celled; capsule bursting transversely; seeds numerous. [J. T. S.]

CYRILLACEÆ. A small family of Dicotyledons, most nearly related perhaps to *Ericaceæ*, although differing in their free petals and anthers opening in slits; or to some of the groups connected with *Saxifragaceæ*. They have also been compared with *Olacaceæ* and with *Aquifoliaceæ*, both of which are much farther removed. They are shrubs or small trees, with alternate

evergreen undivided leaves without stipules, the flowers usually in racemes. There are four or five calyx lobes and petals, and as many or twice as many slightly perigynous stamens. The ovary is two, three, or four-celled, with one pendulous ovule in each cell, and bears as many stigmas as cells. The fruit is usually succulent; the seeds albuminous with an axile embryo. There are about six species known from North or Tropical America, constituting four genera, *Cyrtilla*, *Mylocaryum*, *Elliottia*, and *Purdiana*.

**CYRILLA.** A genus of *Cyrtillaceae*, consisting of plants from the warmer parts of North America, with the habit of some of the larger shrubby species of *Andromeda*. Leaves alternate, wedge-shaped; racemes lateral, elongated, aggregated; flowers small, white, with a five-cleft calyx, five petals, and five stamens; ovary two-celled; capsule fleshy, two-valved, two-seeded. *C. caroliniana* is a handsome greenhouse shrub. [J. T. S.]

**CYRTANDRACEÆ or CYRTANDRÆÆ.** A tribe of *Geraneaceae*, formerly considered as a separate family, including all the Asiatic genera which have no albumen in the seed, whilst the American genera were all believed to be possessed of albumen. These and some other slight distinctions have, however, all proved less constant than had been supposed, and the two groups are now acknowledged to be tribes of one family. The *Cyrtandreae* proper consist of above thirty genera, including *Rumondia* and *Huberia* from Europe, *Aschynanthus*, *Chirita*, *Didymocarpus*, and many others from Asia, *Streptocarpus* from South Africa, *Klugia* from Eastern Tropical Asia and Mexico, and perhaps *Napeanthus* from Brazil.

**CYRTANDRA.** A genus of *Cyrtandreae* *Geraneaceae*, containing a considerable number of caulescent undershrubs or herbs, natives of the Moluccas. They have opposite leaves, equal or frequently with one side dwarfed or aborted. Their flowers are in axillary fascicles or heads, seldom solitary. The calyx is tubular, with five more or less deeply-lobed lobes; the corolla funnel-shaped, with the limb spreading and cleft into five obtuse lobes; there are four to five stamens, two of which only are fertile; the ovary is cylindrical, containing many ovules attached to two two-lobed revolute parietal placentae; the stigma is obtuse or emarginate. The fruit is a many-seeded ovate berry. [W. C.]

**CYRTANTHERA.** A genus of *Acanthaceae*, natives of Tropical America, consisting of some eight species of caulescent shrubs, with broad petiolate leaves, and large scarlet flowers like those of *Aphelandra*, arranged in a beautiful dense terminal thyrse, except in one species, in which they are in axillary cymes. The calyx is cleft into five equal coloured parts; the ringent corolla has a long tube, and the limb is divided into two lips, the lower of which is trifid: there are two stamens

inserted at the base of the tube and adherent to it beyond the middle; the anthers are two-celled; the stigma is obtuse and undivided. [W. C.]

**CYRTANTHUS.** A genus of handsome *Amaryllidaceae*, consisting of bulbous herbs, with two-ranked narrow elongate leaves, and many-flowered umbels of flowers. The perianth has a curved narrow funnel-shaped tube, which is often a little ventricose, and a limb of six short subequal segments; the filaments of the six stamens straight, decurrent, inserted in the upper portion of the tube. They are South African plants, the type of the genus being *C. obliquus*. This has globose bulbs as large as a man's fist, persistent lanceolate entire leaves an inch wide, and an erect scape supporting a loose umbel of numerous pendulous flowers, orange-colour mixed with yellow and green, the tube sensibly widened upwards, an inch and a half long, and the limb spreading, nearly as long as the tube. In another group of the species the leaves are deciduous. One of them, *C. striatus*, has subacute leaves a foot long, and half an inch wide, and an umbel of three or four pendulous narrow funnel-shaped flowers two and a half inches long, red, striped with yellow. *C. odoratus* has fragrant crimson flowers; whilst in *C. colinus* they are poppy scarlet. [T. M.]

**CYRTOCERAS.** *Centrosteima*.

**CYRTOGONIUM.** *Pæciopteris*.

**CYRTOGYNE.** A genus of succulent-leaved undershrubs, belonging to the order *Crasulaceae*, having white flowers in cymes, with a five-parted corolla whose segments are much longer than those of the calyx. The stamens are inserted into the base of the corolla, with whose lobes they alternate, and within them are five small hypogynous scales. The ovary consists of five oblong carpels, gibbous at the top, and ending in long styles. *C. albiflora*, a native of the Cape of Good Hope, is in cultivation. [M. T. M.]

**CYRTOLEPIS.** A genus of *Compositae*, composed of a few small annual herbs, found in northern Africa and Asia Minor. They have much resemblance to the chamomile (*Anthemis*), and are nearly related to that genus, differing only in having winged achenes, the wings toothed, those of *Anthemis* not being winged. They have alternate pinnatisect leaves with linear segments, yellow flower-heads with an involucre of one series of roundish scales, which enclose a large number of tubular five-toothed florets. [A. A. B.]

**CYRTOMIUM.** A genus of polypodiaceous ferns, belonging to that series of the *Aspidiae* which have reticulated veins and peltate indusia. The characteristics of *Cyrtomium*, as shown in the more typical plants, consist in the veins being pinnato-furcate from a central costa, the lower anterior venules being free, and the rest angularly and irregularly anastomosing, forming unequal subhexagonal areoles,

within which two or three excurrent veinlets are produced. Sometimes only the upper venules are anastomosed. The species are robust evergreen pinnate ferns, of very ornamental character, the pinnae being of a

*Cyrtium caryotideum.*

deep shining green, broad, and of a singular rhomb-lanceolate form, sometimes approaching to hastate. The species are few, the typical ones natives of India, China, and Japan, one or two, somewhat anomalous, occurring in South America. [T. M.]

**CYRTONEMA.** Herbaceous plants of the gourd family, *Cucurbitaceae*, with tuberous rhizomes, simple tendrils, and monœcious greenish flowers, the males in clusters, the females solitary. The stamens are five, in three bundles, with straight anther-lobes, and curved filaments thickened at the top. The fruit is a spindle-shaped beaked gourd with three compartments and few seeds. The plants are natives of the Cape of Good Hope. [M. T. M.]

**CYRTOPERA.** A genus of tuberous tropical orchids with a tall radical inflorescence and membranous plaited leaves, sometimes not appearing along with the flowers. Some are American, some Asiatic, a few are South African, and one, *C. plantaginea*, is from Madagascar. *C. Woodfordi*, a plant with dense upright racemes of greenish-purple flowers, is the only one in cultivation. The genus is perhaps hardly distinct from *Eulophia*.

**CYRTOPHLEBIUM.** A name proposed for the species of *Campyloneurum*, a genus of polypodiaceous mostly simple-fronded ferns. [T. M.]

**CYRTOPODIUM.** Under this genus are collected some species of terrestrial orchids from Tropical America, with long fusiform fleshy stems, bearing membranous plaited leaves, and long racemes or panicles of showy yellow or spotted flowers, whose scape rises from the base of the stem. They are very fine objects in cultivation, well grown specimens measuring as much as five feet in height. The handsomest species are *C. Andersoni* and *cardi-ochitum*, brilliant yellow, and *C. punctatum*, the German is the same as *Cyrtopodium Andersoni*.

**CYRTOSIA.** A remarkable genus of

leafless and usually climbing orchids, allied to *Vanilla*, but producing a more or less dry capsule instead of a fleshy aromatic fruit. Few species are known, among which are the *Dendrobium cassythoides* of New Holland, or *Ledgeria aphylla* of Mueller; and the *Erythrorchia* or *Hemmatogchia* of Blume. The best known species is *Cyrtosia Lindleyana* of Sikkim, admirably represented by Dr. J. D. Hooker. This is a stout erect plant, with a great woody root-stock, a strong reddish brown stem, and panicles of bright yellow flowers, succeeded by velvety brown flat pods which after a long time open into flat valves. The seeds are surrounded by a thin jagged wing, which forms a pretty microscopical object.

**CYRTOSPERMUM.** A name applied by Mr. Benthams to a tree growing in tropical South America, forming a genus of *Anacardiaceae*, and yielding a yellow-coloured resin. The calyx is five-parted, and there are ten stamens arising from beneath a hypogynous disc; but the chief peculiarity resides in the drupe-like fruit, whose bony inner shell is divided into two compartments by a hard curved partition; one of these compartments is small and empty, the other forms a horse-shoe-shaped cavity, containing a single seed of the same form attached to the apex of the cavity. The same name has been applied to a genus of *Umbelliferae*, now known as *Lereschia*. [M. T. M.]

**CYRTOSTYLIS.** Under this name are collected a few little Australasian terrestrial orchids, with thin solitary roundish flat leaves, a slender naked scape, and two or three greenish distant flowers. They inhabit dry rocky spots on the edge of ravines.

**CYST.** The spore-case of certain fungals; also the hollow spaces in parenchyma in which oily matter collects, as in the rind of the orange.

**CYSTANTHE.** A genus of *Epacridaceae*, containing a few species, natives of the mountains of Tasmania. They are small glabrous bushes with erect naked stems, marked, as are also the lower portions of the branches, with annular scars, where the leaves, which are sheathing at the base, were inserted. They have a subfoliaceous bracteate calyx; the corolla is a closed conical calyptra, which dehisces transversely a little above its base, the upper part falling away, and the lower being very persistent; the stamens are hypogynous and persistent; the ovary is five-celled, each cell containing many ovules, attached to a pendulous placenta. The plants resemble *Syringella* and *Pittia* in stature and habit; from the first they are separated by the structure of the corolla, and from the second by the ab-

**CYSTEAE.** A fanciful alteration, which has not met with acceptance, of *Cyrtopodis*, the name of a genus of ferns. [T. M.]

**CYSTIDIA.** Saffient cells, accompanying the basidia or asci of fungi; by some regarded as antheridia. [M. J. B.]

**CYSTIDIANTHUS.** A genus of *Asclepiadaceae*, containing a few species of climbing shrubs, natives of the Indian Archipelago, with opposite leaves, and numerous pedicellate flowers in interpetiolar and terminal umbels. The calyx is five-parted; the corolla bell-shaped, five-toothed, and spreading; the staminal corona consists of five fleshy leaves attached to the short gynostegium; the anthers are terminated by a membrane adpressed to the stigma, which is convex, pentagonal, and smooth; the follicles are solitary, long and slender, with numerous comose seeds. This genus has the habit of *Centrostema*. [W. C.]

**CYSTOCAPNOS.** A genus of *Fumariaceae*, containing a glabrous climbing branched herb from the Cape of Good Hope, with stalked twice-pinnate leaves, having three-lobed segments, small white racemose flowers, and bladderly capsule. [J. T. S.]

**CYSTOCARPIUM.** A case including a great many spores; the term is confined to algae.

**CYSTOPTERIDÆ.** A section of polypodiaceous ferns, in which the sori are punctiform or dot-like, and covered by cucullate or fornicate indusia, which, being attached behind them, are inflected over them in the earlier stages. [T. M.]

**CYSTOPTERIS.** A genus of dwarf polypodiaceous ferns, typical of the group *Cystopteridaceae*. In that group, it is distinguished at once by its sori being medial on the veins, that is, placed some distance below the apex. The species, numbering about a dozen, are small membranaceous plants with a tufted or creeping caudex, and twice or thrice-pinnate annual fronds; *C. fragilis*, which has lance-shaped fronds, is a frequent British species; *C. montana*, with a creeping caudex and triangular fronds, has been gathered in a few Scottish habitats. The genus is scattered from the poles to the tropics. [T. M.]

**CYSTOPUS.** Under this name Blume has collected a few little white-flowered Java orchids near *Goodyera*.

The same name is given to a genus of *Fuciniæ*, comprising the white *Uredines* common on *Cruciferae*, but which occur also on *Convolvulus*, *Amaranthus*, &c. The protospores are arranged in necklaces. Oospores have been found deeply seated amongst the mycelium, and De Bary has observed zoospores in *C. candidus*. [M. J. B.]

**CYSTORCHIS.** A genus of terrestrial orchids, allied to *Goodyera*. Blume mentions three species with small pink or yellow flowers. They are especially known by having the glands found inside the lip in so many of these little plants enclosed in a pair of cysts or pockets, whence the name has been formed.

**CYTHESIS.** *Nephelaphyllum*.

**CYTINACEÆ.** The *Cytinus Hypocistis*, either alone or in conjunction with two African root-parasites, *Hydnora* and *Hypolepis*, has been considered as constituting an independent family of very uncertain affinities. It is a native of the Mediterranean region, growing on the roots chiefly of *Cistus monspeliensis*, and rises to a few inches above ground in the form of a tuft of succulent stems covered with imbricated scales, and terminating in a head of flowers, the whole plant of a rich yellow or orange-red colour. The flowers are polygamous, with a tubular four-lobed perianth, and four two-celled anthers, sessile on a central column attached to the perianth-tube. The ovary is inferior, one-celled, with several parietal placentas, and numerous ovules. The plants contain gallic acid, and have been used in consequence as astringents and styptics. [M. T. M.]

**CYTISE A' GRAPPES or AUBOURS or DE VIRGILE.** (Fr.) *Cytinus Laburnum*. —, PETIT. *Cytinus sessilifolius*.

**CYTISOPSIS.** A genus of *Leguminosae*, containing but one species, *C. dorycnifolia*, a small prostrate perennial plant found in the mountains of Syria and Cilicia. This has sessile leaves made up of from three to seven small oblong leaflets, which are covered with silvery hairs; and the axillary yellow flowers have a tubular calyx nearly an inch long, and a corolla of five nearly equal clawed petals, a little longer than the calyx. The pods are narrow, thick, elongated, and contain a number of seeds. The genus is nearly allied to *Anthyllis*, but differs in the sessile digitate leaves, and in the calyx and corolla falling after withering. [A. A. B.]

**CYTISUS.** An extensive and well-known genus of trees and shrubs belonging to the *Leguminosae*. *C. Laburnum*, with which all are familiar under the name of Laburnum, is a native of the mountains of France, Switzerland, and Southern Germany, where it attains the height of twenty feet and upwards. It was introduced into England previously to 1597, at which time Gerard appears to have had it in his garden under the names of *Anagyris*, *Laburnum*, and Bean Trefoil. This and the lilac are the commonest ornamental trees in suburban gardens; but the Laburnum is seen to the greatest advantage when planted in front of loftier trees in a park or extensive shrubbery. The heart wood is of a dark colour, and, though of a coarse grain, it is very hard and durable; it will take a polish, and may be stained to resemble ebony. It is much in demand among turners, and is wrought into a variety of articles which require strength and smoothness. The seeds, it should be remembered, act so violently as an emetic that they are justly deemed poisonous.

*C. purpureus* is an elegant procumbent shrub, a native of Carniola. It seldom exceeds a foot in height, and is either used for ornamenting rockwork, or is grafted on the Laburnum. *C. purpurascens* (Fr. C.

*d'Adam*), the purple Laburnum, is a hybrid between the two preceding. It was originated in Paris in 1823, by M. Adam, and has since been much cultivated in England. A peculiarity of this tree has often been noticed, which is interesting to the physiological botanist as showing the influence exercised by the stock on the scion. 'This purple Laburnum is a hybrid between the common yellow Laburnum and *C. purpureus*. The branches below the graft produce the ordinary yellow Laburnum flowers of large size; those above often exhibit a small purple Laburnum flower, as well as reddish flowers, intermediate between the two in size and colour. Occasionally the same cluster has some flowers yellow and some purple' (*Balfour*). *C. alpinus* differs principally in having its leaves rounded at the base, and in having the pods smooth and few-seeded; whereas *C. Laburnum* has the leaves white with down beneath, and the seed-pods many-seeded and downy. The *Cytisus racemosus* and *rhodopneus*, so generally to be observed among the plants offered for sale in spring in the streets of London, are referrible to *Genista*. [C. A. J.]

**CYTOBLAST.** That elementary spherule, derived from organic mucus, which produces a cell from its side, according to Schleiden. It is the nucleus of R. Brown and others.

**CYTARIA.** A curious genus of ascomycetous Fungi, consisting of a subglobose cartilaginous receptacle in which are sunk a number of ovate pits lined with the hymenium. The mouth of these at last becomes open, and the whole plant has then the appearance of a little waxlike wasp's nest, from whence the genus takes its name. There are three or four species, all of which grow parasitically upon the living branches of evergreen beeches, and one in Tierra del Fuego for several months affords the staple food of the inhabitants. It is, however, almost tasteless, and has been compared to cow-hell. The species are confined to a portion of the southern hemisphere. The individual plants are sometimes solitary, but frequently they form dense clusters, and it is probable that the same branch yields more than one crop from the same spawn. [M. J. B.]

**CHACOKIA.** The name of a group now generally regarded as a subdivision of the genus *Anthericum*, from which it is, however, still sometimes separated. It is distinguished by having the segments of the flower brought together, or connivent into a kind of bell-shaped form, and by having the stamens glabrous. [T. M.]

**DABECOTA.** A section of *Menisleria*, or as it is sometimes considered a separate genus of *Ericaceae*, distinguished chiefly by its tetramerous instead of pentamerous structure, the calyx being four-cleft, the corolla limb four-toothed, the stamens eight, and the capsule four-celled, with four valves. The plant called *D. polifolia* is the St. Dabec's Heath. [T. M.]

**DACHA.** A Hottentot name for *Cannabis sativa*.

**DACRYDIUM.** A genus of *Taxaceae*, consisting of a few evergreen trees inhabiting the East Indies and New Zealand. The distinguishing characteristics reside in the female flower, which consists of a boat-shaped bract, bearing an ovule which at first lies on the scale, but ultimately becomes erect, and when fully developed has a short outer fleshy integument, from which the inner bony investment of the seed protrudes. *D. cupressinum*, which has pendulous feathery branches and slender needle-like leaves, is a very graceful lofty tree. *D. Frankii* is the Huon Pine. *D. taxifolium* is said to acquire a height of 300 feet in New Zealand; its shoots may be made into a beverage having the same antiscorbutic properties as spruce beer. *D. laurifolium*, also a native of New Zealand, is a low growing shrub not unlike *Empetrum nigrum*. [M. T. M.]

**DACRYMYCES.** A genus of tremelloid Fungi, of which *D. stillicatus* is almost universal in the form of small bright-orange gelatinous tear-like masses on decayed pine or larch rails, accompanied sometimes by a larger species, *D. deliquescens*. The former plant has often been supposed to consist of a mass of branched threads, terminated by chains of oblong spores. These, however, are merely conidia, the perfect fruit being developed in the same way as in *Tremella*, and consisting of slightly-curved septate spores, from the edge of which minute secondary spores are given off. The scarlet gelatinous fungus so common on dead nettle stems is now believed to be a condition of *Peziza fusarioides*. [M. J. B.]

**DACTYLÆNA.** A genus of annual herbs belonging to the *Capparidaceae*, and consisting of three species, natives of Brazil. They have a calyx of four sepals, the anterior one longer than the rest; four petals, two longer than the others; five stamens, four of them having filiform filaments without anthers, and the fifth a thickened filament with an elongated bilocular anther. The capsule is stipitate and two-valved. The leaves are alternate, trifoliate, with entire leaflets; and the flowers small racemose. [M. T. M.]

**DACTYLANTHUS.** A genus of *Balanophoraceae*, founded on a root-parasite from New Zealand. It is attached to the roots of beeches and *Pithecopari* by a thick tuberous rhizome, the stems rising in clusters two or three inches from the ground, covered with imbricated scales. The flowers are dioecious, small and numerous, in dense spadices, of which several are clustered together at the summit of the stems surrounded by the upper scales.

**DACTYLICAPNOS.** A genus of *Phanerogamaceae*, distinguished by having the two outer petals bulging out at the base, the fruit berry-like, and the seeds crested. It is considered by Drs. Hooker and Thomson as merely a section of *Dicentra*, from which

it differs only in having the walls of the fruit fleshy. It contains two Indian herbs with weak stems climbing by means of tendrils, compound triternate leaves, and racemes opposite the leaves. [J. T. S.]

**DACTYLIS.** A genus of grasses belonging to the tribe *Festuceae*, and distinguished by the flowers being in very crowded panicles, and subsecund, i.e., pointing nearly all to one side. The glumes are unequal and many-flowered, acute and herbaceous, with terminal setae. *D. glomerata*, the Cock's-foot Grass, is the only British species, and one of the best known of our native grasses. It is also the strongest grower among the superior kinds, and derives its English name from the fancied resemblance the three-branched panicles of flowers bear to the foot of a fowl. It forms a portion of most good pastures, particularly where the soil is loamy or chalky. It is also suitable for sowing alone on boggy land which is in the course of being reclaimed, for, although it does not grow on this sort of soil naturally in great quantities, it produces a good crop when cultivated on it artificially. Steudel describes twenty-nine species, which have a wide range of habitats over the globe. [D. M.]

**DACTYLUM.** A genus of filamentous moulds, of which the genuine species have hyaline threads bearing at their tips clusters of septate spores. *D. roseum*, which was formerly referred to *Trichothecium* from an insufficient knowledge of its structure, belongs essentially to this genus, and is remarkable not only as being one of the most widely-diffused species, distinguished by its delicate pink hue, but as occurring not infrequently in the closed cavities of nuts. The spawn of these delicate moulds will, however, soon penetrate the firmest vegetable tissues if there be proper conditions of moisture. Another species, *D. cogenicum*, occurs in the inside of eggs, where its presence is difficult to account for without having recourse to the wild and unphilosophical notion of equivocal generation. In *D. roseum*, besides the common large spores, there are conidia of a small size, which may have greater power of penetration than the larger. The function, however, of these bodies is uncertain, and they may be spermatia rather than conidia. [M. J. B.]

**DACTYLOCTENIUM.** A genus of grasses belonging to the tribe *Chlorideae*, distinguished by the inflorescence being in finger-like spikes, the flowers on the spikelets pointing to one side; the glumes two, compressed, keeled, and subherbaceous, the exterior one cuspidate; stamens three; ovary smooth; styles two; stigma hairy and branched. There are only seven species described, all natives of Africa, with one exception, *D. radicans*, which is a New Holland grass. They are mostly annuals, and little known in cultivation. [D. M.]

**DACTYLORHIZA.** An affection of some agricultural plants, as turnips and carrots,

in which the root divides and becomes hard and worthless. It is commonly called *Fingers and Toes*, and must be distinguished from anbury, which arises from the attacks of insects. It is in fact not properly a disease, but a tendency to a reversion to the wild state, which can only be remedied by a careful selection of seed. It is sometimes thought that it arises from an unequal distribution of manure, but this is probably a mistake. [M. J. B.]

**DACTYLOSTEMON.** A genus of the spurge-wort family, composed of a number of trees or shrubs found in the tropical parts of South America, and chiefly distinguished by their flowers being destitute of a true calyx, the males containing three, or more generally from four to seven stamens. The leaves are lance-shaped, entire, and glossy; either alternate or whorled, and varying from two to eight inches in length. In their axils the little green flowers are arranged in short catkins, the males towards the apex, and the females near the base, the former entirely naked or accompanied with one or more little scales which represent the calyx, the latter also naked or having a calyx of three small divisions. The fruit is a brown polished three-lobed woody capsule, about the size of a pea, and contains three seeds. The name *Actinostema* is sometimes given to the plants of this genus. [A.A.B.]

**DÆDALEA.** A genus belonging to the spore-bearing section of the higher *Fungi*. In this genus the cavities, instead of being circular or only slightly distorted, are sinuous and intricate from the partial breaking-up of the cell-walls. *D. quercina*, a fungus of a hard corky texture, is not uncommon upon oak stumps or rails, and sometimes makes its appearance in buildings or conservatories, where the wood has been impregnated with its spawn before being felled. [M. J. B.]

**DÆDALEUS.** When a point has a large circuit, but is truncated and ragged. Or, wavy and irregularly plaited as the hymenium of some agarics.

**DÆMONOROPS.** A genus of palms closely allied to *Calamus*, in which the greater number of the forty species referred to it were formerly placed. Its distinguishing peculiarities consist in the flowers being loosely scattered along the branches of the flower spikes, not collected into catkins as in *Calamus*, and also in the spathe or bracts being complete, i.e., entirely enclosing the young spikes. All the species are natives of the eastern hemisphere, principally of the Malayan Peninsula and Islands; they have long thin flexible stems, furnished with pinnate leaves, the prickly stalks of which are frequently prolonged into whip-like tails.

*D. Draco* (formerly *Calamus Draco*) is a native of Sumatra and other islands of the Indian Archipelago, and is called the Dragon's Blood Palm, in consequence of its fruits yielding a portion of the substance known in the arts as dragon's blood. The

fruits are about the size of cherries, and, when ripe, are covered with a reddish resinous substance, which is separated by shaking them in a coarse canvass bag. The resin thus obtained forms the best kind of dragon's blood, while inferior sorts are obtained by boiling the fruits after they have undergone the shaking process. Several varieties of dragon's blood (sticks, reeds, tears, and lumps) are known in commerce, but some are yielded by plants belonging to widely different natural orders. It is chiefly used for colouring varnishes, for dyeing horn in imitation of tortoise shell, and in the composition of tooth-powders and various tinctures. [A. S.]

**DAFFODIL.** *Narcissus Pseudo-Narcissus*, also called Daffy-down-dilly. —, PERUVIAN. *Imeneo Amancaes*. —, SEA. *Imeneo calathina*.

**DAGGER-FLOWER.** *Machæranthera*.

**DAGGER PLANT.** A name for *Yucca*.

**DAHLIA.** A well-known herbaceous plant belonging to the compound flowers, and distinguished by its chuffy receptacle, the absence of a pappus, and by the double involucre of which the outer is many-leaved, the inner of one leaf divided into eight segments. The Dahlia is named after Dr. Dahl, a pupil of Linnæus, but is also known, especially on the continent, by the name *Georgina*. Countless are the varieties of this flower, there are, at the most, only two species in cultivation, *D. superflua*, of which the outer involucre is reflexed, and *D. frutescens*, in which it is spreading; while under the name *D. variabilis* both these are united. The Dahlia is a native of Mexico, where it grows in sandy meadows at an elevation of 5,000 feet above the sea, and from whence the first plants introduced to England were brought by way of Madrid in 1789, by the Marchioness of Bute. These having been lost, others were introduced, in 1804, by Lady Holland. These also having perished, a fresh importation was made from France, when the continent was thrown open by the peace of 1814. The first introduction into France had taken place about 1800; and the plant was cultivated there for the sake of its tubers, which were said to be eatable. Owing, however, to their acrid and medicinal flavour, they found no favour with the human species, and were rejected by cattle. The roots are large, spindle-shaped, and assembled into bundles from the centre of which rises the stem. The flowers, in the examples first introduced, were single, with a yellow disk and dull scarlet rays having a velvety surface. The seeds of these soon produced flowers of various tints, some double, others variegated. Flowers of a better colour and form were successively propagated; in some the petals, or rather forets (for in what is called the 'double Dahlia' the fulness of the flower is owing to the conversion of disk into ray forets), assumed the shape of a horn or funnel with

singular regularity, in others the forets were arranged in the form of a perfect rose. Finally, in the course of years, horticulturists flatter themselves that they have brought the Dahlia to the highest point of beauty, though among the numerous seedlings raised every year, there are constantly occurring individuals which are considered as surpassing their predecessors in some point of floral excellence. A race of pompons with remarkably small flower-heads has been obtained. [C. A. J.]

**DAIS.** A genus of *Thymelæaceæ* or *Daphnaceæ*. Its characters are: flowers surrounded by an involucre; calyx coloured, funnel-shaped, with a four or five-divided limb, and without scales in its throat; stamens eight to ten in two rows, included within the calyx; no hypogynous scales; ovary one-celled, with a single pendulous ovule. Fruit a drupe enclosed by the persistent calyx; albumen fleshy; embryo orthotropical. Shrubby plants found at the Cape of Good Hope and in the tropical and subtropical parts of Asia. There are seven known species. [J. H. B.]

**DAISY.** The common name for *Bellis*. —, AFRICAN. *Athanassa annua*. —, AUSTRALIAN. *Vittadenia triloba*. —, BLUE. *Globularia vulgaris*. —, CHRISTMAS. A popular name for some of the species of *Aster*. —, MICHAELMAS. A popular garden name for *Aster*, especially for *A. Tradescanti*. —, OXEYE. *Chrysanthemum Leucanthemum*. —, SWAN-RIVER. *Brachycome iberidifolia*.

**DAISY-STAR.** *Belldiastrum*.

**DALBERGIA.** A large genus of leguminous forest trees and climbing shrubs principally inhabiting the tropics of the Eastern Hemisphere. Most of the species have pinnate leaves with numerous leaflets arranged alternately, but sometimes reduced to three leaflets only. The flowers are borne in axillary racemes, and have a bell-shaped calyx, the mouth of which is cut into five divisions, a papilionaceous corolla, and nine to ten stamens, either all joined together into a sheath, which is split along the upper side, or divided into two equal bundles of five each. The pods are thin, very much flattened, not winged, and either long and straight, or short and crescent-shaped, containing one or several flat seeds.

*D. latifolia*, the Black-wood or East Indian Rose-wood tree, and the Sit-al of the Bengalese, is common on the Malabar and Coromandel coasts, and forms a magnificent tree, yielding one of the most valuable furniture woods. The timber is procurable in planks four feet broad, exclusive of the sap-wood, and is of a dark purplish colour, very heavy, close-grained, and susceptible of a fine polish. It comes to this country under the names of Black-wood and East Indian Rosewood, but it has not the agreeable perfume of the true rosewood, nor is it marked with the black lines of resinous matter which add so much to the beauty and value of the East-

lian wood. In India it is greatly used for making the most expensive descriptions of furniture. *D. sissooides*, is a smaller tree, but yields an equally valuable timber, which also goes by the names of Blackwood and Rosewood in Madras, where it is employed in the construction of gun-carriages. See *TRIPTOLOMEA*.

*D. Sissoo* is an East Indian species, but found farther north than either of the preceding, abounding principally in Bengal and the provinces as far north as the Punjab. It is a large and very rapid-growing tree, yielding a strong tenacious compact timber of a dark brown colour, but not so fine-grained as the Blackwood. This wood is called *Sissoo* or *Sissum*, and being very durable it is included among those which are authorised to be employed for the sleepers of Indian lines of railway. In Bengal it is used in the construction of gun-carriages, and it also supplies the ship-builders of that presidency with crooked timbers and knees, besides which it is extensively employed for all the ordinary purposes connected with house building. [A. S.]

**DALEA.** A genus of sub-shrubby or herbaceous plants of the pea family found in America, appearing in greatest numbers in New Mexico, and having their northern limit in the United States, and their southern in Chili, very few being found in the north-eastern part of the continent. Its most marked features are the flowers in terminal spikes, and the pods small, one-seeded, and not longer than the calyx. Its nearest affinity is with *Petalostemon*, in which the stamens are five, while here they are generally ten, and never fewer than nine. In the great bulk of the species the leaves are unequally pinnate, and composed of numerous small wedge-shaped or oblong leaflets, which are often covered with small glandular dots like those seen in the St. John's-wort. The white, yellow, pink, or purple flowers are about the size of those of a vetch, and arranged in terminal spikes or heads; the calyx nearly equally five-toothed or cleft; and the keeled petal and wings united with the staminal tube and jointed to it, but the standard or upper petal quite free. The little pod is wholly enveloped in the calyx.

One of the most remarkable species is *D. spinosa*, which inhabits the desert regions of California, and has simple narrow leaves, and large deep violet flowers arranged in a spiked manner on the spiny-pointed branches. The plant attains a height of four or five feet. Like many desert plants the stems have a bleached appearance. *D. arborescens*, found in the Sierra Nevada mountains, is remarkable as being the only one which attains the dimensions of a small tree. *D. Jamez* attains only a height of about six inches, and is altogether covered with silky hairs; it is also remarkable as being the only species with trifoliate leaves. Upwards of sixty species are enumerated. The genus is named in honour of Thomas Dale, an English botanist of the last century. [A. A. B.]

**DALECHAMPIA.** A genus of spurge-worts found in the tropics of both hemispheres. Their slender stems are generally found twining among bushes, but sometimes scrambling to a great height amongst trees. The leaves are alternate, stalked, heart-shaped, entire or three to five-lobed, sometimes divided to the base. The small green flowers are borne on stalked heads which proceed from the axils of the leaves, a circumstance that at once serves to distinguish the genus. The heads contain a number of flowers of both sexes, and are enveloped by an involucre of two leafy, beautifully veined green or coloured bracts. The male flowers have a four or five-parted calyx, and very numerous stamens; the females a calyx of five or six divisions which are often fringed with hairs, and an ovary surmounted by a cylindrical or club-shaped style, which is entire, with a terminal or lateral stigmatic opening. The fruit is a three-celled three-lobed capsule about the size of a large pea. The names *Cremophyllum* and *Rhopalostylis* are given by some authors to plants of this genus. [A. A. B.]

**DALHOUSIEA.** A simple-leaved Leguminous shrub found in Angola and the Himalayas, where it bears its white blossoms in May, and ripens its pods in the end of the season. Its beautifully veined glossy leaves are stalked, oval, and entire; the peduncles which arise from their axils are once or twice forked, and at the points of forking furnished with small round bracts; each flower is also supported by two similar bracts, which completely hide the five-toothed calyx. The upper petal or standard is deeply notched, and the ten stamens are quite free to the base. The dark brown polished pods are of a woody consistence, from three to four inches long, tapered at each end into a sharp point, and containing two or three flat seeds. The simple leaves, bracted peduncles, and free stamens, together with the nature of the pods, are its most marked features. [A. A. B.]

**DALIBARDA.** A genus of herbs or small shrubs with white or yellow flowers, belonging to the *Rosaceae*, distinguished from the allied genus *Rubus* by having dry fruit, and terminal, not lateral, styles. The herbaceous species, which are hardy, have creeping stems and solitary flowers; they may be grown in a peaty soil, and are fit for ornamenting rock-work. The shrubby species have the flowers in panicles, and being natives of Java require to be grown in a hot-house. [C. A. J.]

**DAMAR.** A viscid resinous product of *Ceanothus microcarpum*.

**DAMAS. (Fr.)** *Hesperis matronalis*.

**DAMASONIUM.** An aquatic herb belonging to the *Alismaceae*, better known under the name of *Actinocarpus Damasonium*. It is found, though somewhat rarely, in our ponds and ditches, and forms a tuft of radical floating or emergent long-stalked leaves, from amongst which issues the

flower-stem bearing usually two whorls of white flowers. They are each succeeded by six or eight two-seeded carpels, arranged in the form of a star. [T. M.]

**DAME D'ONZE HEURES.** (Fr.) *Ornithogalum umbellatum*.

**DAMIER.** (Fr.) *Fritillaria Meleagris*.

**DAMMARA.** A genus of *Coniferae* or *Pinaceae*, the name of which is derived from the native one in Amboyna. Flowers dioecious, that is, some with stamens only, and

*Dammara obtusa*.

others with pistils only on separate plants; the staminate flowers in catkins, the numerous stamens having very short filaments, and eight to fifteen-coiled anthers; the pistillate ones in ovate or globular cones with persistent scales without bracts. There is a single unequal-winged seed with two cotyledons under each scale. The species are large trees with scattered leathery leaves. They are found in the East Indian Islands, New Zealand and New Guinea.

*D. australis*, the Kauri Pine of New Zealand, is a tree from 150 to 200 feet in height, producing a hard brittle resin like copal. *D. macrophylla* is a large tree 100 feet high, found on Vanicolla, one of the Queen Charlotte Islands in the South Sea. *D. Moorit* is a tree forty feet high, found in New Caledonia. *D. obtusa* is a large timber tree used in ship-building, found in the New Hebrides. *D. orientalis*, the Amboyna Pine, is a tree of the Moluccas, 100 feet high, which yields the fine transparent resin called Dammar, [J. H. B.]

**DAMMER TREE, BLACK.** *Canarium strictum*. — **WHITE.** *Vateria indica*, the resin of which is called Dammer pitch.

**DAMOUC.** An Arab name for *Nitraria fridentata*, which is believed to be the Lotus tree of the ancients.

**DAMPIERA.** A genus of *Goodeniaceae*, named after the celebrated navigator Captain W. Dampier. It is distinguished by having a calyx whose limb is short or ob-

solete; a monopetalous, two-lipped, blue or purple corolla, the segments of the upper lip of which are auricled on the inner margin; five stamens with coherent anthers; and a style with a stigma seated at the base of a cup, termed an indusium. The flowers are axillary or terminal; and the leaves alternate. The plants, which are shrubby or herbaceous, are natives of Australia and Tasmania. [R. H.]

**DAMSON.** A small austere variety of plum. — **BITTER, or MOUNTAIN.** *Samaruba amara*.

**DANÆA.** A remarkable genus of ferns of the danæine division of the *Marattiaceae*. The species are not very numerous, and are all South American or West Indian. They have large woody rhizomes, and pinnate rarely simple fleshy coriaceous fronds, the pinna of which are usually articulated. The fertile fronds are more or less contracted. The sori are very remarkable; they are linear, occupying the whole length of the veins, and crowded so as to cover the whole under-surface of the divisions of the fertile fronds. The sporocases are consolidated into a fleshy mass, which represents an involucre, each fleshy case at length opening at the top by a small round pore, so that the contiguous fructiferous ridges appear to be each pierced by a double line of small apertures. In some species represented by *D. nodosa*, which has the joints of the fronds thickened, the sori are affixed to the veins by

*Danæa alata* (fructification).

their whole length; in others, as in *D. stenophylla*, they are said to be affixed only by the centre. [T. M.]

**DANÆACEÆ.** The name of a natural order of ferns, also called *MARATTIACEÆ*; which see.

**DANÆOPSIS.** A doubtful genus of ferns, separated from *Danæa*, on the ground of its having anastomosing veins. Nothing definite, however, appears to be known of the plant. [T. M.]

**DANCING GIRLS.** *Mantisia callistaria*.

**DANDELION.** *Taraxacum Dens Leonis*, the Dent de Lion.

**DANEWORT.** *Sambucus Ebulus*.

**DANGLE-BERRY.** An American name for *Gaylussacia frondosa*.

**DANTHONIA.** A genus of grasses belonging to the tribe *Aveneae*, distinguished by the glumes being two or many-flowered; the outer pale smooth and coriaceous below, many or sometimes nine-nerved, emarginate at the apex, with an intermediate broad tooth, which sometimes terminates in a geniculate twisted awn; stamens three; styles two. Sixty species are described, nearly all natives of South Africa, and many of them useful there as pasture grasses. [D. M.]

**DAPANIA.** A genus considered by Korthals to belong to *Chrysobalanaceae*, but referred to *Oxalidaceae* by Planchon, who considers it closely allied to *Averrhoa*. The hypogynous flowers, and five-celled fruit with pendulous exalbuminous seeds, are sufficient to distinguish it from the *Chrysobalanaceae*. [J. T. S.]

**DAPHNOCEÆ.** A natural order of monochlamydeous dicotyledonous plants, synonymous with *THYMELACEÆ* or *THYMELAOCEÆ*; which see. [J. H. B.]

**DAPHNADS.** A name used by Lindley for the *Thymelaceae*.

**DAPHNE.** A well-known thymelaceous genus of shrubs, the species of which are very widely distributed, being found in the temperate and tropical parts of Europe, Asia, America, and Australia. The flowers are hermaphrodite; the calyx tubular, its limb divided into four segments; petals none; stamens eight, inserted in two rows upon the inner surface of the tube; ovary one-celled, style short, stigma button-shaped; fruit a drupe. Many of the species are remarkable for the beauty and fragrance of their flowers; while all have a more or less stringy bark, and all are more or less acrid.

*D. Mesereum*, the Mesereon, a common shrub in cottage gardens in this country, where it is also, though rarely, found wild, is remarkable for the appearance of its fragrant pink flowers in early spring before the leaves expand. It forms a dwarf bush with erect branches, along the sides of which the flowers are placed, while the leaves occur in tufts at the extremity of the twigs. The fruits are red and pulpy, of the size of a pea, and poisonous to human beings, though birds eat them with avidity. There is a variety with white flowers and yellowish fruits. The bark of this species, and especially that of its roots, has been used in medicine as a sudorific and alterative in scrofulous, venereal, and other diseases. It is extremely acrid to the taste, and is now rarely employed.

*D. Laureola*, the Spurge Laurel, occurs in woods in this country. It is a smaller plant than the preceding, and has bright green oblong evergreen leaves, and greenish flowers which are scentless; the fruits are oval and of a bluish-black colour. This species participates in the acrid properties

of the mesereon, though it is not employed in medicine. It finds a place in shrubberies, on account of its evergreen character, and because it thrives well beneath the shade of trees.

The tough fibrous nature of the inner bark of these plants is made available for the manufacture of paper in various parts of India and China. In Nepal the bark of *D. cannabina*, *D. Edgeworthii*, and other species is thus employed. For this purpose it is scraped and boiled in water, with a small quantity of the ashes of the oak; after this it is washed and beaten to a pulp on a stone, and then spread out on a mould or frame made of bamboo mats. This paper is of various qualities; the best is strong and tough, is not liable to crack or break upon being folded, is not eaten by insects, and does not suffer from damp. From its durability it is used in many parts of India for deeds and records.

Several kinds are cultivated in this country as hardy shrubs or in greenhouses. Among them are *D. pontica*, which resembles the common spurge laurel, but is of larger growth, has more fragrant flowers, and grows well under the shade of trees; *D. alpina*, a low growing shrub with deciduous leaves and white fragrant flowers, well adapted for rock-work; as also is *D. Cneorum*, a charming plant with procumbent stems, lance-shaped evergreen leaves, and clusters of pink sweet-scented flowers. The foregoing are hardy. *D. odora*, *D. indica*, *D. chinensis* and others require the protection of a greenhouse. The Spurge Laurel is the badge of the Gramine.

**DAPHNIDIUM.** Indian trees constituting a genus of *Lauraceae*, having unisexual flowers within an involucre of scaly bracts. The perianth is six-lobed; the male flower has nine stamens in three rows, the three innermost having glands at each side of their filaments. Fruit berry-like, one-seeded, partly enclosed within the persistent base of the perianth. [M. T. M.]

**DAPHNIDOSTAPHYLIS.** A small group of shrubby plants, separated by some from *Arctostaphylos*.

**DAPHNOPSIS.** A genus of *Thymelaceae*, consisting of dictyous Brazilian plants. The male flowers have a four-lobed perianth, with eight stamens, and a rudimentary ovary. The perianth of the female flower is persistent at the base of the drupe, which is of a fibrous texture. [M. T. M.]

**DARBYA.** A North American tree or shrub, described by A. Gray as constituting a distinct genus of *Santalaceae*, but reduced by A. De Candolle to a section of *Comandra*.

**DAREA.** A section of *Asplenium*, sometimes called *Campopteris*, and characterised by the prevalence of unisporiferous segments to the fronds. [T. M.]

**DARLINGTONIA.** A remarkable one of *Sarraceniacae* found in California; only species, *D. californica*, known as

Californian Side-saddle flower or Pitcher plant, is a perennial herb growing in marshy places. Its leaves all rise from the root, the adult ones being from eighteen inches to a foot or more in length, the stalk or pitcher tubular, gradually tapering downwards and singularly twisted on the axis about half a turn, marked with strong veins and slender veinlets, and the summit vaulted and formed into a sac about the size of a hen's egg, on the under side of which is an oval orifice about half an inch in diameter opening into the cavity of the pitcher; the upper part of this tube is of a dull orange colour. The blade, which is borne on the end of the stalk or pitcher, is narrowed at the base and deeply divided into two spreading nearly lance-shaped lobes, which are curved downwards, and also often backwards, resembling the lop-ears of some varieties of rabbit. The pitcher inside the hood is furnished with short conical hairs which point downwards, and towards the base there are long slender hairs also pointing downwards; remains of insects are sometimes found at the bottom. Dr. Torrey writes 'The orifice of the pitcher being placed directly under

*Darlingtonia californica.*

the vaulted summit, cannot receive either rain-water or dew, and yet Mr. Brackenridge thinks he found some of the leaves containing water; still I cannot think the water was secreted by the hairs in the tube. The flowers are single and nodding at the apex of a smooth stalk, which is furnished with straw-coloured scales, and varies from two to four feet in length. When fully expanded the flower is about two inches in diameter; the calyx consists of five straw-coloured acute sepals; the petals, of a like number, and pale purple in colour, are narrowed and concave at the apex and broad below; the twelve to fifteen stamens are nearly hidden by the projecting summit of the ovary, which is top-shaped, slightly five-angled, and crowned by a short style with a five-lobed stigma. The fruit is a five-celled capsule about an inch in length, with numerous seeds. The forked blade of the leaf and the form of the stigma distinguish the genus from

*Sarracenia*, which has an umbrella-shaped stigma. The genus is named in honour of Dr. Darlington, of Pennsylvania.

This account is chiefly abridged from a paper of Dr. Torrey's in the *Smithsonian Contributions to Knowledge* (Washington 1853), where a full history of this interesting plant is given. It is met with as a rarity in cultivation in England. [A. A. B.]

**DARNEL.** *Lolium temulentum.*

**DARWINIA.** A small genus of *Chamaelauceae*, named after Dr. Darwin. It has a five-cleft calyx, the lobes of which are roundish-cordate, concave, and full of pellucid dots; petals wanting; stamens from ten to fifteen, often joined in threes, inserted in the limb of the calyx, and having very short flat glabrous filaments, and anthers inserted by their bases; style tapering, bearded at the apex; stigma a pruinose dot; ovary one-celled, single-seeded; seeds pentagonal pitted on the surface. Heath-like shrubs of lowly growth found in the extra-tropical portions of Australia. The leaves are marked with pellucid dots, [B. H.]

**DASYA.** A lovely genus of rose-spored *Algae*, allied to *Polysiphonia*, from which it differs in its more compound stem, with persistent coloured branchlets, which originate the pod-like receptacles of the tetraspores or stichidia. The species are far more common in the Southern Ocean. We have, however, a few fine species, of which *D. coccinea* is well known to most collectors of *Algae* from its bright scarlet tint; and there are representatives in the Northern Hemisphere of four out of the five sub-genera into which Dr. Harvey has disposed the species in his *Nereis Australis*. In *Polysiphonia*, it may be observed, the tetraspores are imbedded in the branches themselves, and not in distinct organs. [M. J. B.]

**DASYCLADEÆ.** A small natural order of green-spored *Algae*, which are either naked or coated with carbonate of lime, and have a one-celled simple or branched axis which is whorled either throughout its whole length or near the summit with jointed branchlets. The fruit is contained in free or laterally united sporangia. In *Acetabularia* the stem is filiform, and ends in a target-shaped disc composed of spore-bearing cells; from the centre of this the stem is continued bearing whorls of forked fibres, and as the fruit cells fall off below, new discs are formed above. *Dasycladus*, the typical genus, has threads free from any crust, and the axis is clothed everywhere with whorls of jointed trifid branchlets. The thread-shaped forked distinctly jointed frond of *Oymatophora*, on the contrary, is densely incrustated, the crust being pierced with pores, and the nodos fringed with hyssoid multifid fibres. We have no representative of this curious order on our coasts. Both *Dasycladus* and *Valoniaceae* were first separated by Kützinger from *Siphonot*, and are adopted by Dr. Harvey in his admirable work on North

American *Alga*, to which we have been largely indebted, [M. J. B.]

**DASYLIRION.** A genus of *Bromeliaceae*, consisting of Mexican plants with short stems, and densely crowded linear leaves which droop gracefully, and generally have a little brush-like tuft of fibres at the point. From amid these leaves the flower-stalks rise to a considerable height, the upper portion being crowded with a dense panicle of flowers, which are dioecious. The perianth consists of six nearly equal segments in two rows; and there are six stamens with filaments thickened in the middle, and having a gland at the base. The female flowers differ in having antherless stamens, a superior six-seeded one-celled ovary, with membranous angles, the six ovules in pairs; a short style with a dilated three-lobed stigma; and a nut-like fruit, one-seeded by abortion. *D. acrotrichum* is a handsome kind grown in greenhouses. [M. T. M.]

**DASYLOMA.** The generic name of plants belonging to the umbelliferous order, characterized by having five ribs on each half of the fruit, three on the back smaller than the two at the sides, the latter being larger and thicker, a character indicated by the name, which is derived from two Greek words signifying 'thick border.' The species are natives of India, and are herbaceous plants, with hollow stems, and twice pinnate leaves, the leaflets of which are wedge-shaped, toothed at the end. [G. D.]

**DASYMALLA.** A genus of small West Australian bushes of the *Myoporum* family, having their leaves and stems covered with dense white wool. The forked style and bracted flower-stalks, together with the woolly nature of the stems and leaves, are its chief distinguishing features. The four-angled stems are furnished with opposite entire leaves, oblong obovate in form. In the axils of these the flowers are found in little bundles or cymes shorter than the leaves. The calyx is five-parted, and the purple tubular corollas are widened at the top and two-lipped, the upper lip two-lobed, the lower three-lobed. In the inside of the tube and near its base the four stamens (two long and two short) are inserted. The ovary is densely hairy and crowned with a filiform style forked at the top; when ripe it becomes a somewhat dry four-celled berry with one seed in each cell. Two species are known. [A. A. B.]

**DASYNEMA.** A name once given to a few South American trees of the lime-tree family; they, however, belong to *SLOANEA*: which see. [A. A. B.]

**DASYPHYLLUM.** *Flotovia*.

**DASYPOGON.** A genus referred to *Juncaceae*, in which it is distinguished by its capsular one-celled fruit with basilar ovules, and longitudinally dehiscient incumbent anthers with filaments thickened at the apex. It comprises two undershrubs from South Australia, with simple leafy stems, and grass-like leaves rough at the

margin; flowers sessile in a globular terminal head. [J. T. B.]

**DASYSTEMON.** A name given by De Candolle to a plant from the Jardin des Plantes, which was supposed to have been raised from Australian seeds. Mr. Bentham, however, shows that it is founded on a mistake. The stamens, with thick ovoid filaments, forming the chief character of and giving the name to the genus, are not so figured by De Candolle in his *Plantas Grasses*: probably on a first hasty examination the carpels were taken for stamens. The plant is *Crassia capensis*, a South African, not an Australian, species—an error as to origin very common in botanic gardens. [J. B.]

**DATE.** *Phoenix dactylifera*. WILD, *P. sylvestris*.

**DATISCAEAE.** (*Datiscaes*.) A natural order of dicotyledonous plants included in the sub-class *Monochlamydeae*, and referred by Lindley to the cucurbital alliance. Herbs or trees with alternate leaves having no stipules; some flowers have stamens only, others have pistils only; the corollas wanting; the calyx or perianth adheres to the ovary, and is divided into three or four parts; stamens three to seven; ovary one-celled, with three or four many-seeded parietal placentas. Fruit a one-celled capsule, opening at the top; seeds having a reticulated skin, and a cup-like swelling at one end; there is no separate albumen. The plants consist of few species, which are scattered over North America, northern India, Siberia, the Indian Archipelago, and the south-eastern part of Europe. They have bitter and purgative qualities. It is said that the ovary of *Datisca coccinifera* can produce perfect seeds without the application of pollen to the pistil. *Tetrameles Horsfieldii* is a large tree of the order. There are but three known genera, *Datisca*, *Tetrameles*, and *Tricrassia*, and these comprise but four species. [J. H. B.]

**DATISCA.** A genus of plants typifying the *Datiscaes*. The characters are: flowers dioecious; calyx five-parted in the staminate flowers, three to five-toothed in the pistillate flowers; no corolla; stamens five to fifteen, collected in the middle of the flower; ovary united with the calyx, inferior, one-celled, with three to five parietal placentas; styles three to five. Fruit a one-celled capsule opening by a round hole at the apex. Seeds numerous, striated, with a cup-like covering at the base. Annual herbaceous plants found in Nepal and in Asia Minor. They have unequally-pinnate alternate leaves, and racemose bracteated greenish flowers. There are two known species. [J. H. B.]

**DATLIER COMMUN.** (Fr.) *Phoenix dactylifera*.

**DATURA.** A genus of *Solanaceae*, or, according to Mr. Miers, of *Atropaceae*, the species of which are eminently poisonous; while in small quantities they act as valuable remedial agents. They are known by their tubular calyx, the upper part of

which falls off as the fruit ripens, while a small portion remains as a circular rim around the base of the fruit; the corolla is funnel-shaped and plaited. The fruit is a capsule with four compartments and four valves.

The best known plant of this genus is the common Thorn Apple, *D. Stramonium*, which springs up in a half wild state on the borders of cultivated fields, rubbish heaps, &c., in this country, and is found in similar situations in all the warmer parts of the globe. It is a coarse strong-smelling annual, growing one or two feet high, with widely-spreading forked branches, and large ovate leaves with irregularly-waved or sinuately-toothed margins. The flowers are large, placed on short stalks arising from the forks of the stem; the calyx is tubular and angular; the corolla is double the length of the calyx, funnel-shaped, with a large plaited five-toothed limb, generally of a pure white colour, but sometimes in hot climates pink or purple; the capsule is ovate, of the size of a walnut, somewhat four-celled, bursting by four valves, which are covered with stout triangular spines, whence the name Thorn Apple. The poisonous principle of this plant is an alkaline crystalline substance called *daturin*. The effects produced by medicinal or poisonous doses of *Stramonium* are similar to those induced by belladonna, but to this is added a certain degree of acridity and of anodyne power not possessed by the other plant. *Stramonium* has been found beneficial in neuralgia, epilepsy, mania, &c.; while in some cases of asthma relief has been experienced from smoking the leaves.

*D. fastuosa*, a common Indian plant, is possessed of properties similar to those of *stramonium*, and is employed by the native doctors for the relief of rheumatic and other painful affections. The seeds are used in India and China to stupefy or even poison an enemy. *D. alba* or *D. Metel*, also an Indian plant, produces similar effects. The Rajpoot mothers are said to smear their breasts with the juice of the leaves, so as to poison their newly-born female infants. It has been conjectured that the seeds of *D. Stramonium* were used by the priests of Apollo at Delphi to produce those frantic ravings which were called prophecies, a suggestion which derives some support from the fact that in the temple of the Sun, in the city of Sagomozo (Peru?), the seeds of the Floripondio, *D. sanguinea*, are used for a similar purpose. The Peruvians also prepare an intoxicating beverage from the seeds, which induces stupefaction and furious delirium if partaken of in large quantities. The Arabs of central Africa are said by Lieut. Burton to dry the leaves, the flowers, and the rind of the rootlet, which is considered the strongest preparation, and smoke them in a common bowl, or in a water-pipe. It is esteemed by them a sovereign remedy for asthma and influenza, and although they do not use it like the Indian *Datura* poisoners, accidents

nevertheless occur from its narcotic properties. See BRUGMANSIA. [M. T. M.]

**DAUBENTONIA.** A genus of bushy plants of the pea family, comprising three species found in Texas and Buenos Ayres. They are chiefly remarkable for their curious quadrangular pods, which are three to four inches long, stalked, pointed, and furnished with wings along the angles. The only other genus with four-angled pods nearly related to this is *Pisacidia*, which has *unequally* pinnate leaves; while here there is no odd leaflet, but the leaves are made up of ten to twelve pairs of oblong leaflets, each about an inch in length. The red or yellow flowers, a good deal like those of the laburnum, are borne on axillary racemes shorter than the leaves. *D. punicea* is a common plant on the banks of the Uruguay, and in various parts of Banda Oriental and Rio Grande, where it grows into a large handsome shrub with leaves like those of the false acacia, and bears abundant racemes of brilliant red flowers, between cherry and orange-colour. The genus is named in honour of M. Daubenton, an eminent French naturalist and physician. [A. A. B.]

**DAUBENYA.** A genus of one or two species of bulbous *Liliaceæ* from the Cape of Good Hope. *D. aurea*, the typical species, has a pair of oblong leaves seated close to the earth, and in their sinus a sessile umbel of yellow flowers, whose perianth is tubulose with a two-lipped limb, both lips being three-toothed, the upper short, the lower one larger in the ray flowers and decapitated in those of the centre or disk. There are six stamens with unequal declinate filaments, somewhat joined at the base; and a filiform style with a capitate stigma. The genus is dedicated to Prof. Daubeny of Oxford. [T. M.]

**DAUCOSMA.** A North American genus of *Umbelliferae*, represented by an annual herb, with the odour of the wild carrot, whence its name. Its distinguishing characters are its petals, which are bent inwards; its five-toothed calyx; and its distinct carpophore or stalk bearing the two halves of the fruit. The first of these characters separates it from *Cynosactidium*, the second from *Ethusa*, and the last from *Eranthe*. [M. T. M.]

**DAUCUS.** A genus of *Umbelliferae*, consisting of several species of dwarf weedy-looking plants, having thin deeply-cut pinnatifid leaves; and flower-stems rising from two to three feet high, and bearing in a terminal umbel a number of small white or rosy-coloured flowers. It is distinguished by the long prickles to its carpels, the prickles being long, flat, and straight. Of one of its species cultivated as a vegetable, there are many varieties.

The Carrot, *D. Carota*, is a biennial, a native of Britain, usually found, in its wild state, in light sandy soil. Notwithstanding the great difference between its dry sticky root, and that of the large succulent root of our garden Carrot, it is

generally admitted to be the stock from which all the cultivated varieties have sprung; although Miller states that he in vain endeavoured to improve the quality of the wild plant by cultivation. As an esculent, the Carrot was known to the ancients; and Pliny says the best came to Rome from Candia. Gerard, writing in 1597, tells us they do not grow in Candia only, but are found upon the mountains in Germany, and about Geneva. How or when they were first introduced into this country is unknown, but it is generally believed to have been by the Dutch during the reign of Queen Elizabeth (1558), and that they were first grown about Sandwich in Kent.

Scarcely any vegetable is better known, or in greater demand for culinary purposes than the Carrot. Its root contains a large portion of saccharine matter, and is used in soups and stews, as well as a vegetable dish during winter. In order to supply the demand for young carrots during the spring and summer, large quantities are grown by artificial heat. The various sorts of Carrots in cultivation are divided into two classes, known as Horn Carrots and Long Carrots: the former short and early; the latter becoming mature in autumn for winter use.

Parkinson, writing in 1629, says, that in his day ladies wore Carrot leaves in place of feathers; and Loudon states (*Encycl. of Gard.*, p. 835) that in winter an elegant chimney ornament may be formed by cutting off a section from the head or thick end of a Carrot, containing the bud, and placing it in a shallow vessel of water. Young and delicate leaves unfold themselves, forming a radiated tuft of a very handsome appearance. [W. B. B.]

The Carrot yields two British species, *D. Carota* and *maritima*; but we agree with Sir W. J. Hooker in deeming them 'scarcely permanently distinct.' The Carrot of the garden and farm is a well known derivation of one of these; we almost think of the latter, as our experiments in ennobling the common *D. Carota* have been unfortunate, though we have had reports of success in this experiment by those with whom the ennobling of the parsnip has not succeeded as it has with us. [J. B.]

DAUPHINELLE. (Fr.) *Delphinium*.

DAURADE. (Fr.) *Ceterach officinarum*.

DAVALLIA. A fine and extensive genus of polypodiaceous ferns, typical of the group *Davalliee*. They have scaly creeping rhizomes, which feature has given rise to the name of Hare's Foot Fern, applied to *D. canariensis*. The fronds are sometimes pinnate, but more frequently pinnately compound, very elegantly cut into multitudes of small divisions, and bearing numerous fructifications, which form a series of cups or cysts at the margins of the segments. These cysts assume two somewhat different forms: the one, rather shallow cup-shaped, represented by *D. tenaxifolia* and *D. aculeata*, the latter of which is

quite scandent and bramble-like in habit; the other tubulose, represented by *D. elegans* and *D. solida*. The genus is well marked by natural features, and is one of the most elegant to be found in our gardens. Several offshoots have been separated from it, as *Acrophorus*, *Humata*, *Loxoscaphe*, and *Microlepia*. [T. M.]

DAVIESIA. A large genus of New Holland and Tasmanian bushes of the pea family, easily recognised among their allies with ten free stamens and two ovules, by the form of their pods, which are short, nearly triangular, with a straight upper and a much curved under edge. In some species the leaves are much like those of the juniper, and in a large number they take the form of spines like those seen on the furze, to which plant many of them bear a strong resemblance. In a few the leaves are heart-shaped and embrace the stem; in others they are oblong; and a few are entirely destitute of leaves, but in these the stems are usually flattened and perform leaf functions. The flowers are small, usually yellow, sometimes blue or purple, arranged in little tufts or racemes or stalked cymes arising from the axils of the leaves, or from those of little scales where no leaves exist.

A very common plant in greenhouses, and one of the most beautiful in the genus, is *D. latifolia*, a native of Tasmania and the south parts of New Holland. This plant has smooth oblong leaves, in the axils of which the pretty yellow flowers are found disposed in dense erect racemes. Another scarcely less beautiful species is *D. cordata*, the leaves of which, about the largest in the genus, are sessile, heart-shaped, acute, and embrace the stems at the base; they are quite smooth and beautifully veined. The flowers are in stalked corymba, each supported by two leafy bracts which envelope a number of stalked flowers having a yellow standard and a purple keel. *D. epiphyllum*, a West Australian species, is remarkable for having white flattened and variously lobed stems without leaves, but having much the appearance of the antlers of a stag. The flowers are curiously placed on the middle of the flattened portion, and arise from the axils of little scales, two or more together. *D. juncea* has rush-like branches devoid of leaves, and furnished at distant intervals with bundles of yellow flowers; and an allied species has similar but much thicker stems, nearly half an inch in diameter, with soft pith-like wood. It would be difficult to point to a genus comprising more diversity of form among its species, of which there are fifty-five known. It bears the name of the Rev. Hugh Davies, a Welsh botanist. [A. A. B.]

DAVYA. A genus of small opposite-leaved trees or scandent bushes of the *Melastomaceae*, found in various parts of tropical America, and numbering about a dozen species. They are chiefly characterised by the capsular (not horrid) fruit, and the peculiar structure of their sta-

mens, which are eight to ten in number, nearly equal in height and similar in form; the anthers linear or awl-shaped, curved outwards and opening at top by a little pore; the connective or point of junction of the anther with its stalk produced behind into an obtuse or acute horn, sometimes forked at the point and parallel to the anther. The leaves are stalked, lance-shaped, oval or elliptical, entire or toothed. The flowers are yellow, rose, or purple, disposed in terminal panicles or cymes, and having an entire or five-toothed calyx; five obovate petals, and a filiform style crowning an ovary which becomes, when ripe, a five-celled capsule with numerous seeds. The genus bears the name of Sir H. Davy, the eminent chemist. [A. A. B.]

**DAY-FLOWER.** An American name for *Commelina*.

**DEAL.** The wood of various pine and fir trees.

**DEALBATE.** Covered with a very opaque white powder.

**DECA.** In Greek composition = ten.

**DECAISNEA.** A genus of plants named after Decaisne, a celebrated French botanist.

*Decalinea insignis*.

ist, by Drs. Hooker and Thomson. It belongs to the natural order *Lardizabalaceæ*, and is an erect shrub with large pith, pinnate leaves, racemose inflorescence, and greenish flowers; sepals six, linear and awl-shaped; petals none; flowers sometimes abortive or becoming staminate or pistillate; stamens six, free or united by their filaments; ovaries three with an oblique style; ovules very numerous, on two thread-like placentas. The fruit consists of follicles filled with pulp. The only known species is *D. insignis* found at Sikkim and Bhutan in the Himalaya at the height of 6,000 to 10,000 feet, flowering in May and fruiting in October. The fruit is very palatable, and is eaten by the Lepchas of

Sikkim. The name is also a synonyme of *Cnemidia*. [J. H. B.]

**DECAMALEE or DIKAMALI.** A gum obtained in India from *Gardenia lucida*.

**DECANEMA.** A genus of *Asclepiadaceæ*, containing a single species from Madagascar. A leafless branched undershrub, remarkably like *Sarcostemma aphylla*, except in the structure of the flower. The flowers are small in terminal or lateral umbels; the calyx is five-parted; the corolla rotate and five-cleft; the staminal crown consists of two series of five lobes, the outer being opposite to the inner alternating with the lobes of the corolla, and its lobes are rounded and terminate in a long linear blade exceeding the corolla. The long round follicles contain comose seeds. [W. C.]

**DECASPORA.** A small Tasmanian genus of *Epacridaceæ*, having small ovate or lanceolate leaves, and flowers in terminal spikes of a reddish hue. The calyx with two bracts at the base; corolla campanulate, the limb slightly bearded; stamens exerted with five scales united at the base; a ten-celled ovary with a single seed in each cell. The fruit is a violet-coloured berry. [R. H.]

**DECIDUOUS.** Finally falling off; as the calyx and corolla of crucifers.

**DECKERIA.** A name recently proposed for a genus of palms, but the characters upon which it is founded not being of sufficient importance to warrant its adoption, other botanists have since referred the species to the older genus *Tristea*, to which three of them originally belonged. They are natives of tropical South America, and are remarkable on account of the singular shape of their trunk, which,

*Deckeria ventricosa*.

though cylindrical throughout its entire height, like that of numerous other palms, while young, after attaining a certain age, swells suddenly out at a point about mid-

way between the ground and its crown of leaves, to more than double its previous diameter, again contracting to its original size and cylindrical form at a short distance from the summit. This peculiarity is more particularly evident in the species called by the Indians on the Amazon *Paxiuba barriguda* (i.e. pot-bellied *Paxiuba*: *Paxiuba* being a general term applied to the *Iriartea*s), the *Peckeria* or *Iriartea ventricosa* of botanists, a common palm in the forests bordering the Amazon and Rio Negro, where the natives take advantage of its swollen trunks in the construction of their canoes, its natural shape saving them much labour. They also use the hard black wood of the outer portion of the trunk to make harpoons for spearing the cow-fish. [A. S.]

**DECLINATE.** Bent downwards.

**DECODON.** A genus of *Lythraceæ*, nearly related to *Lythrum*, and differing chiefly in the calyx-tube being shortly bell-shaped, instead of cylindrical. *D. verticillata*, the Swamp Loosestrife, grows on the borders of swamps in the United States, and is the only known species. It is a pretty bush six to eight feet high, having slender recurved stems furnished with privet-like leaves, placed in whorls of three round the stem, and bearing in their axils clusters of stalked rose-coloured flowers much like those of *Lythrum Salicaria*. The plant is also called *Nesaea verticillata*. According to Torrey it is used as an emmenagogue. [A. A. B.]

**DECOMPOUND, DECOMPOSITE.** Having various compound divisions or ramifications.

**DECUMARIA.** A climbing shrub of the Southern States of North America, forming a genus of *Philadelphaceæ*. The flowers are white, arranged in corymbs, sweet-scented, and in gardens are observed to be sometimes unisexual, though this has not been found to be the case in wild specimens. The calyx-tube is adherent to the ovary, and is marked by from seven to ten prominent nerves; the style is consolidated, expanded above into a stigma, with seven to ten rays. The capsule is divided into seven to ten compartments, and is crowned by the persistent style and limb of the calyx. It contains not only numerous seeds, each surrounded by an aril, but also, at least in dried specimens, a quantity of small crystals (raphides) interspersed among them. [M. T. M.]

**DECOUMBENT.** Reclining upon the earth, and rising again from it.

**DECURRENT.** Prolonged below the point of insertion, as if running downwards.

**DECURSIVELY PINNATE.** When a petiole is winged by the elongation of the base of the leaflets; hardly different from pinnatifid.

**DECOSSATE.** Arranged in pairs that alternately cross each other.

**DEDUPLICATION.** The supposed unlining process which some botanists believe in when one organ in a flower is produced opposite another.

**DEER BALLS.** A synonym of Hart's Truffles, *Lycoperdon Nuts*, and *Elaphomyces*. [M. J. B.]

**DEERBERRY.** *Gaultheria procumbens* also an American name for *Vaccinium stamineum*.

**DEERINGIA.** A genus of *Amaranthaceæ*, distinguished by its fruit being a many-seeded berry. They are smooth weak-stemmed shrubs from India and Australia, with alternate leaves, and spikes of small flowers, having a five-leaved calyx, five stamens united below into a cup, a short style, three stigmas, and an inflated berry. *D. celosioides*, from New Holland, bears long spikes of red berries, about the size of currants. [J. T. S.]

**DEFERENT.** Conveying anything downwards.

**DEFOLIATION.** The casting off of leaves.

**DEFORMATION.** An alteration in the usual form of an organ by accident or otherwise.

**DEGRADATION.** A change consisting of an abstraction, loss, abortion, or non-development of usual organs.

**DEHAASIA.** A genus of *Lauraceæ*, consisting of trees with hermaphrodite or monocious flowers, the perianth of which is six-cleft, the three outer divisions being much smaller than the inner ones. Stamens nine or twelve in three or four rows, the inner row sterile; of the fertile stamens, the two outer rows have their anthers opening inwardly, while those of the inner row open outwardly, the filaments of this latter series having glands on each side at the base. The fruit is a one-seeded berry placed upon a thickened fleshy flower stalk. [M. T. M.]

**DEHISCENCE.** The act of splitting into regular parts, or in some manner dependent upon organic structure.

**DELABECHEA.** The Bottle-tree of North-eastern Australia, *D. rupestris*, is the only plant of this genus, which belongs to the *Sterculiaceæ*, and is very nearly related to *Brachychiton*. The Bottle tree is of middling stature, and is chiefly remarkable for the curious form of the trunk, which is bulged out in the middle in the form of a barrel. The stem abounds in a mucilaginous or resinous substance resembling gum tragacanth, which is wholesome and nutritious, and is said to be used as an article of food by the aborigines in cases of extreme need. Dr. Lindley, in describing the tree, says, 'the wood has a remarkably loose texture; it is soft and brittle, owing to the presence of an enormous quantity of very large tubes of pitted tissue, some of which measure a line and a half across; they form the whole inner

face of each woody zone. When boiling water is poured on shavings of this wood, a clear jelly resembling tragacanth is formed, and becomes a thick viscid mass; iodine stains it brown, but no trace of starch is indicated in it. Usually the leaves are from two to four inches long, entire, stalked, and lance-shaped; sometimes, however, they are digitate and composed of seven to nine sessile leaflets of the same form as the simple leaves. The digitate leaves are probably found only on young plants. The flowers are inconspicuous, and borne on short panicles arising

*Delabecchia rupestris.*

from the axils of, and shorter than, the leaves; in the males the calyx is five-cleft, and the stamens numerous; the females are not known. The fruit is composed of five stalked smooth brown leathery foliicles, covered internally with a thick fur of starry hairs; each of these contains about six seeds, which have their lower portion covered with similar hairs, and are smooth above. The genus is named in honour of the late eminent geologist, Sir H. T. De la Bèche. [A. A. B.]

**DELAIREA.** The name sometimes given to a trailing South African Groundsel (*Senecio mikanioides*), with stalked, smooth, and fleshy leaves, which are cordate at the base, and five to seven-lobed. The flower-heads are numerous, and disposed in axillary corymbs longer than the leaves. In gardens it is called Geranian Ivy. [A. A. B.]

**DELASTREA.** A genus of *Sapotaceae*, represented by a lofty tree native of Madagascar, distinguished from its allies by the lobes of its corolla, which are eighteen in number, twelve external, six internal, opposite to which latter are six stamens, all of them fertile; and by its ovary, which contains twelve compartments. [M. T. M.]

**DELESSERIA.** A genus of rose-spored Algae, belonging to the section in which the spores form little necklaces (*Desmiodermata*) containing many of the most beautiful and delicate species which adorn

our coasts, a great part of their beauty arising from the symmetry of the frond, and the contrast between the dark midrib and the membranous border. The capsules contain a placenta formed of branched threads bearing short chains of spores, the ultimate members of the chains being the first to ripen. The species are numerous, and many of them are widely dispersed. The beautiful ash-leaved seaweed formerly called *D. sanguinea*, has fruit of a different structure, and is now referred to a distinct genus, *Wormskioidia*. [M. J. B.]

**DELIMA.** A small genus of *Dilleniaceae*, all, with the exception of one Asiatic species, natives of the tropics of the Western hemisphere. They have very small flowers disposed in loose panicles at the ends of the young branches; the calyx consisting of five permanent sepals, and the corolla of four or five white petals, which soon fall away. The ovary is solitary, nearly globular, and terminated by a curved tapering style; it ultimately becomes a small dry oval fruit, which splits open along the inner edge when ripe, exposing a solitary arillate seed.

*D. sarmentosa* is widely distributed throughout the eastern countries of tropical Asia, including Ceylon, Malaya, Ava, Sikkim, Java, Southern China, the Philippine Islands, &c. Its leaves vary very much in shape, but are generally somewhat oval; their edges either entire or cut into teeth tipped with short hard points; the upper surface of these leaves is completely covered with little asperities, which are so hard and render the leaves so rough that they are commonly employed in most of the above-mentioned countries as a substitute for sand-paper, and are thus used for polishing various domestic utensils, and other articles made of either wood or metal. In Ceylon the plant is called Korasawel, and in the Philippine Islands, Bois de râpe. [A. B.]

**DELIQUESCENT.** Branched, but so divided that the principal axis is lost trace of in ramifications; as the head of an oak tree.

**DELISSEA.** A genus of shrubs, natives of the Sandwich Isles, and included in the order *Lobeliaceae*. The main characteristics of the genus are a hemispherical calyx tube, which is united to the ovary, and is surmounted by a limb with five very short teeth; a tubular corolla with a two-lipped limb; filaments and anthers combined into a tube; fruit a somewhat globular berry, two-celled, crowned by the limb of the calyx. [M. T. M.]

**DELOSTOMA** (including *Codazzia*). A genus of *Bignoniaceae*, remarkable for its double calyx, and flat oblong capsule divided into two cells by a partition placed contrary to the direction of the valves. There are four species, all confined to the Andes of South America, where they range from New Granada to Peru. They are small trees, with simple oblong leaves generally covered with hair, and terminal panicles

bearing fine pink or purple blossoms. The outer calyx is five, the inner three-cleft; the corolla tubular, slightly curved; the stamens four in number; the capsule smooth, with the winged seeds arranged in several rows. One of the handsomest species is *D. integrifolium* (*Codazzia spectosa*), frequent in the Andes of Quindiu. *D. latifolium* is identical with *Callichamys riparia*, and *D. stenolobum* with *Stenolobium stans*. *Amphilophium* is the only other bigoniaceae genus which has a double calyx. [B. S.]

**DELPHINIUM.** A genus of *Ranunculaceae*, commonly known by the name of Larkspur. The species are numerous, and widely distributed over the temperate regions of the Northern hemisphere. They are herbaceous plants, with erect branching stems, and finely cut or palmately-divided leaves. The flowers are in loose racemes towards the end of the branches; they have a calyx of five-coloured sepals, the upper one prolonged at its base into a long tapering spur, and four (or two) petals concealed partially within the spur of the calyx. The fruit consists of from one to five many-seeded follicles. The flowers resemble those of some species of *Aconite*, but they have a spurred, not a hooded calyx, and they have not the peculiar hammer-like petals of the *aconite*. Larkspurs partake largely of the acrid properties for which the order is in general so remarkable.

*D. Staphisagria*, or *Stavesacre*, was used medicinally by the Greeks, and until recently found a place in the British pharmacopœia, though now rarely used. The seeds contain the active principle in greatest abundance, and hence are ordered to be used in the form of oilment to destroy vermin. Delphinia is an extremely acrid bitter white powder prepared from the seeds, and used externally in cases of rheumatism and neuralgia. Numerous species and varieties of this genus are cultivated in gardens. *D. Consolida* is a common European plant; its name was given in reference to its power, real or imaginary, of healing or consolidating wounds. *D. Ajacis*, a common garden plant, occasionally found in a half-wild state on the borders of fields, derives its name from certain markings on the petals, presenting more or less resemblance to the letters A I A I; hence also it has been conjectured to be the 'hyacinth' of the ancients, described as possessing similar markings. Dr. Daubeny, the latest commentator on the plants mentioned in ancient Greek and Latin writers, concludes, 'that the term *hyakinthos* was in general applied to some plant of the lily tribe; but that the poets confounded with this the larkspur, which has upon it the markings alluded to; and that the name hyacinth was given, in the first instance, to the plant which most distinctly exhibited them.'

Some of the cultivated species, such as *D. grandiflorum*, *D. chinense*, *D. sibiricum*, &c., are called Bee Larkspurs, from the re-

semblance of the petals, which are studded with yellow hairs, to a humble bee whose head is buried in the recesses of the flower. One of the most beautiful species in cultivation is *D. formosum*, with large rich blue flowers; and *D. cardinale* is remarkable for its scarlet flowers. [M. T. M.]

**DELTOÏD.** A solid, the transverse section of which has a triangular outline, like the Greek Δ. Also applied to the outline of thin bodies.

**DEMATIEL.** A natural order of filamentous moulds, separated from the white or brightly-coloured species by the dark threads, which look as if they were smoked or carbonised; and in the more typical species have an investing membrane. Some of our common moulds, as *Cladosporium herbarum*, belong here. [M. J. B.]

**DEMERSED.** Buried beneath water.

**DEMIDOVIA.** A genus of *Trilliaceae*, founded on the *Paris incompleta* of Bieberstein. It differs from *Paris* by not having any inner series of perianth segments. The leaves are six to twelve, oblong or oblong-oblancoate, acuminate; the perianth segments green, ovate acuminate, twice as long as the eight to twelve stamens; styles four, longer than the stamens. The only species, *D. polyphylla*, is a native of southern Russia. [J. T. S.]

**DENDROBIUM.** A well-known genus of epiphytal orchids, comprising more than 200 species, of which upwards of eighty have been cultivated in hothouses for the sake of their beautiful flowers. The great mass comes from India and its Archipelago; a few are found in East Australia and the Pacific Islands; and one in New Zealand. 'The genus varies extremely in the habit of its species, some being little larger than the mosses among which they grow; while others are surpassed in stature by few in the order. Like the *Oncidia* of the New World, there are some species of which the foliage is ancliptous, others having it terete, while in the majority it is in the usual flat condition. A few have no other stem than a wiry creeping rhizome; others have small conical pseudo-bulbs; many form clavate horny stems, leafy only at the summit; but the greater part produce long leafy branches. In the majority the colour of the flowers is some shade of purple; a few are destitute of all colour except green; and a rather considerable group is especially distinguishable by the rich yellow tint of their blossoms.'—*Lindley*. In arrangement, the flowers are either solitary, fascicled, or in racemes. According to Dr. Lindley, all agree in having a two-celled anther with four pollen masses, which have no caudicle or separate stigmatic gland, and are of uniform breadth at either end; the latter character separating them from *Bria*, which bears pear-shaped pollen masses; whilst, from the nearly-related genus *Bobophyllum*, they may be recognised by the sessile and not unguiculate (clawed) lip.

Of cultivated species, with flowers in which purple predominates, we have *D. nobile*, perhaps the most beautiful in the genus. It has erect stems one to two feet high, bearing at intervals two or three-flowered peduncles, the flowers when expanded being two to three inches across. The petals and sepals are faintly rose-coloured at the base, and bright purple towards apex; the lip rolled up so as to be nearly trumpet-shaped, with a recurved border which is greenish-yellow at the edges and purple at the end, while the tube is of a deep blood-red colour. There are a number of fine varieties of this plant cultivated. *D. macranthum*, from Manila, has rich rose-coloured flowers, sometimes five inches across; the ovate lip is margined with a delicate fringe of hairs, and marked at the base on either side with a deep purple blotch. *D. Macarthur*, called in Ceylon Wissak-mal, meaning rainy-month flower, has slender stems one to two feet long, and three to five-flowered racemes; the flowers of a pale purple, three inches wide. *D. Falcateri*, from Bhutan, is readily recognised by the markedly tumid joints of its slender stems; the beautiful large solitary flowers have pale rose-coloured petals and sepals tipped with dark purple, the lip having a deep purple blotch at the base bordered by a yellow ring. These are all lovely plants. In the yellow-flowered group we have *D. Ambriatum* from Nepal, with racemes of fine yellow flowers from near the apex of the naked stems; a variety of this occurs with a deep red spot at the base of the beautifully fringed lip. *D. densiflorum* has stout stems which end in a tuft of glossy leaves, setting off to great advantage the fine dense clusters of drooping golden-yellow flowers: this is one of the finest in the genus. Mr. Darwin, in his book on orchids, gives an account of the self-fertilisation of *D. chrysanthum*, which belongs to this group. Amongst a host of species with drooping stems, we have *D. Pierardi*, with delicate pale lilac flowers; and the beautiful little *D. Devonianum*, named after the late Duke of Devonshire, the lovely flowers of which have a white ground colour, the sepals and petals tipped with pink, and the heart-shaped frilled lip marked with a pink blotch at the apex, and two yellow spots near the base. No collection should want the *D. Hillii*, of Australia, which is an improvement on the better known *D. speciosum*. Its stout stems bear a number of large glossy green leaves, and a profusion of dense flowered racemes, the creamy-white narrow-petaled flowers of which have a highly agreeable odour. The generic name is derived from the Greek, signifying tree and life, from the plants living on trees. [A. A. B.]

**DENDROCHILUM.** A genus of orchids found growing on branches or trunks of trees in the Malayan Archipelago. They have short and fleshy pseudo-bulbs, each with a single coriaceous leaf, and their small green, white, or yellowish flowers are arranged in slender, terminal, or lateral

spikes six to eight inches long; the bracts arranged in a two-ranked manner. The anther is two-celled, with four incumbent pollen masses; while the column has two short horns in front, and the lip is entire. About a dozen species are known; of which one is *D. glumaceum*, a very pretty Philippine island plant, cultivated in orchid houses for the sake of its graceful drooping spikes of ivory-white flowers, the leaves resembling those of the lily of the valley; and another is the graceful little *D. filiforme*, in which the flowers are bright yellow. [A. A. B.]

**DENDROID.** Divided at the top into a number of branches, so as to resemble the head of a tree; only applied to small plants like mosses.

**DENDROLOBIUM.** A genus of small leguminous trees found in the tropical countries of the eastern hemisphere, but in greatest abundance in India. They only differ from *Desmodium* in their small jointed pods, about an inch in length, being somewhat rounded, and in the disposition of the flowers. The leaves are made up of three oblong or oval leaflets, usually downy or covered underneath with silvery hairs. The flowers, in little axillary fascicles or umbels, are white and inconspicuous. [A. A. B.]

**DENDROMECON.** A genus of shrubby *Papaveraceæ* found in California, and having two ovate caducous sepals, four petals, numerous stamens with filiform filaments and linear anthers, two short thick sessile stigmas, and a siliquaform one-celled two-valved pod, with a marginal placenta and numerous seeds. *Dendromecon*, literally Tree Poppy, is a most appropriate name, the plant having all the aspect and character of the poppy tribe, combined with a woody stem and branches. The species, *D. rigidum*, has lance-shaped glaucous leaves, and yellow flowers resembling those of *Meconopsis cambrica*. [T. M.]

**DENDRON.** In Greek compounds = a tree.

**DENDROPEMON.** A genus of *Loranthaceæ*, parasitic shrubs from the Antilles, with small white or purplish flowers in simple racemes, rarely paniculate or corymbose. It differs from *Loranthus* in having the alternate anthers abortive, the style filiform, and the flowers conspicuously bracteated. [J. T. S.]

**DENDROPTHOE.** A genus of *Loranthaceæ*, natives of Australia, Asia and the Cape of Good Hope, distinguished from *Loranthus* and its near allies by having the petals united into a tube. They are parasitic shrubs, with long green yellowish or purple flowers, the peduncles several flowered, racemose or fasciculate. [J. T. S.]

**DENDROSERIS.** A few small trees peculiar to the island of Juan Fernandez make up this composite genus, which is nearly allied to the hawk-weeds, though the plants have more the appearance of gigantic sow-

thistles, from which they are, however, easily recognised by their tawny pappus hairs, those of sow-thistles being silvery white. The stems seldom exceed twelve feet in height. The leaves vary much in form and size, some being entire and two or three inches long, while others are a foot or more in length, and pinnatifid. The flower-heads few and large in some, or numerous and small in others, are arranged in terminal panicles, and the numerous florets are either of a white or tawny-yellow colour. The achenes, compressed or triangular with winged angles, are crowned with a pappus of rough unequal hairs.

The most striking species of the genus is *D. macrantha*, whose lower leaves are stalked, oblong, coarsely toothed, and obtuse, while the upper ones are small and entire, and clasp the stem by their base. The flower-heads are more than an inch in diameter. Seven species are enumerated. The name *Rea* is sometimes given to these plants. [A. A. B.]

**DENHAMIA.** A genus of tropical Australian trees or shrubs of the spindle-tree family, chiefly distinguished by their bony capsules and numerous seeds. Their pale-green stalked leaves are oval or lance-shaped, and have entire or spiny margins. The flowers are small, green, arranged in terminal panicles, and have a five-cleft calyx, five petals, and five stamens, inserted on a sinuate fleshy ring. The fruits are imperfectly three or five-celled bony capsules, the seeds being enveloped in a beautiful red aril. *D. heterophylla* has some of its branches furnished with lance-shaped entire leaves, and others with oval leaves having spiny teeth like those of the holly. Three species are known. [A. A. B.]

**DENISONIA.** The only species of this genus, which belongs to the vervain family, is *D. ternifolia*, a North Australian bush, with straight stems clad with glandular hairs, and a great abundance of mint-like leaves, which are sessile, oval and sharply toothed. The little rose-coloured flowers are single in the axils of the leaves and shortly stalked, the corollas being two-lipped. The genus bears the name of Sir W. T. Denison, governor of New South Wales. [A. A. B.]

**DENNSTÆDTIA.** A genus of herbaceous ferns of the group *Dicksoniæ*, distinguished from *Dicksonia* itself, chiefly by having a cup-shaped instead of a two-valved indusium, this being reflexed so as to stand at a right angle to the plane of the frond. They have creeping rhizomes, and for the most part large herbaceous bipinnate or decomposed fronds. *D. punctilobula*, *D. cicutaria*, *D. apifolia*, &c., are familiar examples. The same group has been sometimes called *Sitobolium*, or by error *Sitobolium*. [T. M.]

**DENS.** A toothing; adj. **DENTATE.** Having sharp teeth with concave edges. When these teeth are themselves toothed, the part is *duplicato-dentate*; not *bidentate*, which means two-toothed.

**DENTARIA.** A genus of herbaceous perennials belonging to the *Crucifera*, and closely allied to *Cardamina*, from which it differs in having broad seed-stalks, and in its creeping roots being singularly toothed; hence the systematic name, and the English one of Toothwort. There are many species, which inhabit mostly the temperate regions of Europe and America, and are ornamental plants with terminal corymbs of light purple, sometimes white or yellow flowers. The roots of *D. diphylla* have a pungent mustard-like taste, and are used by the natives of the mountains of North America, from Pennsylvania to Canada, instead of mustard, under the name of Pepperwort. The genus is represented in England by *D. bulbifera*, a slender plant about eighteen inches high with pinnate leaves and a few pretty light purple flowers. In the axil of every stem-leaf is a small bulb of a purple hue, by which the plant, which rarely perfects seeds, is propagated. It is confined to the woods of Kent, Surrey, Middlesex, Herts, and Bucks, creeping extensively by means of its curiously toothed white roots, and forming dense patches. The root-leaves are all pinnate, those of the stem pinnatifid, the upper ones nearly simple. [C. A. J.]

**DENTATO-CRENATE.** The same as *Crenato-dentate*.

**DENTATO-LACINIATE.** When toothings are irregularly extended into long points.

**DENTATO-SERRATE.** When toothings are taper-pointed and directed forwards, like serratures.

**DENT DE CHIEN.** (Fr.) *Erythronium Dens Cantis*.

**DENT DE LION.** (Fr.) *Taraxacum Dens Leonis*.

**DENTELAIRE.** (Fr.) *Plumbago europæa*.

**DENTELLA.** Little creeping annuals, natives of marshy places in India and the Indian Islands, constituting a genus of *Cinchonaceæ*. The flowers are small, white, on axillary flower-stalks, with a roundish hairy calyx-tube united to the ovary; the limb of the calyx is five-cleft; the corolla is funnel-shaped with a dilated throat, its limb five-cleft, each of the petals having on either side a small acute tooth-like process; the stamens are concealed within the corolla; and the fruit is a two-celled berry, surmounted by the lobes of the calyx. [M. T. M.]

**DENTICULATE.** Having very fine marginal teeth.

**DENUATE.** When a surface which has once been hairy, downy, &c., becomes naked.

**DEODAR.** *Abies*, or *Cedrus*, *Deodora*.

**DEOPERCOLATE.** A term used in describing mosses, when the operculum will

not separate spontaneously from the spore-cases.

**DEPAUPERATE.** When some part is less perfectly developed than is usual in plants of the same family; thus, when the lower scales of the head of a cyperaceous plant produce no flowers, such scales are said to be depauperated, or starved.

**DEPPEA.** The name of a Mexican shrub of the cinchona family, the wood and bark of which are of a red colour. The flowers are yellow arranged in cymes; the limb of the calyx has four small teeth; the corolla is wheel-shaped; the filaments are very short, nevertheless, the anthers project from the corolla; the fruit is a capsule bursting by two valves. [M. T. M.]

**DERMA.** In Greek compounds = the bark or rind.

**DERMIS.** The skin of a plant.

**DESCENDING.** Having a direction gradually downwards.

**DESERT ROD.** *Eremostachys*.

**DES'ESPOIR DES PEINTRES.** (Fr.)  
*Saxifraga umbrosa*.

**DESFONTAINEA.** The name of a genus of Peruvian shrubs of doubtful affinity, but somewhat allied to *Solanaceae* and *Gentianaceae*. The leaves are thick with spiny margins like those of a holly; the flowers are axillary, stalked, five-parted; the corolla tubular, more than twice the length of the calyx, the lobes of its limb imbricated before expansion; stamens five, concealed within and attached to the corolla; anthers opening longitudinally; ovary one-celled with five parietal placentae; style thread-like. The fruit is berry-like with numerous seeds. *D. spinosa*, with its deep green spiny leaves, and splendid scarlet flowers, is a most ornamental greenhouse plant. [M. T. M.]

**DESICCATIO.** In very hot countries, and in dry seasons in those which have a more temperate climate, not only is the duration of annual plants cut short, but many perennials fall a sacrifice. Trees which send their roots down deeply into the soil may stand the trial better, while those with more superficial roots suffer; but even in climates like our own, two years of annual drought like 1858 and 1859 will cause the death of many a deep-rooting tree, where the vitality was previously low. Where plants have suffered from want of water, a too liberal supply at once is apt to bring mischief; and in young trees which have been long kept out of the ground, the application of damp moss to the bark in a shady place is better than immediate planting. [M. J. B.]

**DESMANTHUS.** A genus of tropical and subtropical Indian and American herbs of the leguminous family. The stems seldom exceed three feet in height, and are furnished with twice-pinnate leaves composed of numerous small leaflets like those of the sensitive plant; the

leaf-stalks are furnished with one or more glands, and at their base are two small setaceous stipules. The small green or white flowers are numerous, and borne in round stalked heads which arise from the axils of the leaves, and consist of a bell-shaped calyx, five petals, and five or ten stamens, though sometimes flowers are found in which there are neither stamens nor pistil. The pods are flat, smooth, membranaceous, several-seeded, and about an inch in length; when ripe they split into two portions, while in *Mimosa*, to which this genus is nearly allied, they break up into as many portions as there are seeds. The little brown polished seeds of *D. virgatus* are in Jamaica strung like beads, and used for making bracelets, work bags, &c. *D. brachylobus* is a Texan plant, sometimes known as *Darlingtonia*; but that name is now given to the Californian pitcher plant. [A. A. B.]

**DESMIDIACEÆ.** A natural order of green-spored *Algae*, remarkable for their mode of reproduction, and for the eccentric and varied forms assumed by many of the species. The more typical species of the group, as the name implies, consist of a chain of connected joints, increasing by the continued addition of two new half-joints in the centre, so that the two extreme members of the chain are the oldest and the two in the centre the youngest. In the majority of instances, however, the disarticulation takes place on the formation of the first new half-joints, in such a manner that the two new individuals consist of half the old plant connected with half of the new, a mode of increase which obtains also in *Diatomaceæ*. Fructification takes place, though rarely, by the conjugation of two individuals by means of lateral tubes or simple contact, as in *Conjugata*, the spore affecting a variety of interesting forms, and being often strongly spinulose, the spines being occasionally complicated in structure. The new individual is produced from this by the formation of a vertical partition in the centre, and the subsequent formation of two new half-joints, so that the proper form of the species is not attained till the third generation, if so soon.

*Desmidiaceæ* differ from *Diatomaceæ* in their green colour, and the absence of siliceous walls. The general appearance of the plants, moreover, is totally different. They occur in pools, running streams, &c., and appear to be more frequent in Europe than elsewhere; though North America produces many species, and *Closteria* occur in the Himalayan collections. We are not aware that they are ever attached at any period of growth. In one or two instances the endochrome is spiral or not equally diffused. In general the joints are deeply constricted, but this is not always the case, and in *Closterium*, in which the plant consists of two elongated curved cones applied to each other by thin bases, there is not the slightest constriction. In this genus the joints are often as distinctly

grooved or striate as in *Diatomeae*. Besides the increase of the species by means of cell division and spores, minute zoospores with lash-like appendages have been discovered in *Pediastrum*, a genus which belongs to a small group in which the cells remain united so as to form a little flat frond. In *Osterium* there is, moreover, an organ at the extremity of the frond consisting of a cell inclosing active molecules. This is probably the male apparatus. The armed spores are sometimes found in a fossil state enclosed in flints and other transparent minerals. Like *Diatomeae*, Ehrenberg has attempted to refer them to the animal kingdom, but all good authorities seem now convinced that the proper place is amongst the *Algae*. Mr. Ralfs' beautiful work on *Desmidiaceae* may be consulted by those who wish for fuller details. It does not appear that any individual of the order can be applied to any economical purpose. [M. J. B.]

**DESMIOSPERMEZ.** One of the main divisions of rose-spored *Algae*, in which the spores are not scattered or simple, but form distinct chains like little necklaces. These are attached to a placenta, which may either spring from the walls or their base, or may be strictly central. Far the larger portion of the more compound species belong to this section. [M. J. B.]

**DESMOBRYA.** A term proposed to designate that group of ferns in which the fronds are produced terminally, that is, from the apex of the caudex, and are adherent to it: see *ENKOBRYA*. [T. M.]

**DESMOCLADUS.** An Australian genus of *Restiaceae*, a sedge-like plant, with the branches of the stem rigid, the barren ones awl-shaped, the flowering ones with a single ovate few-flowered spike. [J. T. S.]

**DESMODIUM.** An extensive genus of herbs, shrubs, or small trees, of the pea family, found more or less in all extra-European countries, but chiefly confined to the tropics. They are easily recognised by the form of their pods, which are flat, straight or curved, with two or many joints, each jointed portion enclosing one seed; in form, size, and thickness, they are much like the blade of a pen-knife, but the under edge is always notched, and occasionally the upper also. The leaves are commonly made up of three leaflets, but sometimes they are simple and lance-shaped or linear. The flowers are white, pink, purple, or blue, and usually disposed in terminal or leaf-opposed racemes or panicles; they have a bell-shaped four or five-toothed calyx, five narrow petals, and ten stamens, all inserted into a tube or one of them free. The most interesting, although by no means the most beautiful, plant in the genus is *D. gyrans*, the Moving plant, a native of India, and often found in cultivation in plant stoves; its leaves are made up of three oblong or lance-shaped smooth leaflets, the two lateral ones much the smallest. The flowers are violet, and arranged in terminal racemes. The singu-

lar rotatory motion of the leaflets of this plant renders it an object of great interest. In the trembling poplar, the leaf-stalk is so constructed that the least breath of wind causes the leaf to whirl; in the sensitive plant when the leaves are touched,

*Desmodium gyrans.*

they are perceptibly affected; but in this the motion in the leaves goes on if the air be quite still, and they are scarcely influenced by mechanical irritation. The leaflets move in nearly all conceivable ways, but do not fold on themselves; two of them may be at rest and the other revolving, or all three may be moving together. Sometimes one leaf or two on the plant only are affected, and at others the movement is nearly simultaneous in all the leaves. More commonly the lateral leaflets are seen to move up or down, either steadily or by jerks. The movements are most evident if the plant be in a close hothouse with a strong sun shining. It is said that by arresting the vital action going on in the leaflets, by giving them a coating of gum, and thus preventing transpiration and respiration, the movements are stopped, but that they recommence when the gum is removed by water. Upwards of 130 species are known, chiefly from the tropics of America, Africa, and India. [A. A. B.]

**DESMONCUS.** A genus of palms inhabiting the forests of tropical America. They have long slender flexible stems, and pinnate leaves with the leaf-stalks prolonged into whip-like tails, resembling in general appearance the calami of the Eastern Hemisphere, and like them also, they climb over and amongst the branches of trees, and support themselves by means of the hooked or recurved spines attached to all parts of their leaf-stalks. The flower spikes are simply branched, and have male flowers upon the upper, and females upon the lower part of the branches. The males have a thin three-cornered calyx, a corolla

of three petals of thicker substance than the calyx, and six stamens with narrow erect anthers; and the females have a cup-shaped calyx with the rim entire or divided into three small teeth, a bell-shaped corolla with the mouth drawn in, and an ovary with one perfect and two imperfect cells, surmounted by a short style and three sharp stigmas. The fruit is small and nearly round.

*D. macracanthos*, the Jacitara of the Amazon and Rio Negro, grows fifty or sixty feet long, with a stem not thicker than an ordinary cane, and either climbs up trees or trails among the underwood, where it offers an annoying obstruction to persons wearing clothes, the sharp curved spines upon its leaves taking such firm hold of the garments that great care and patience are required to detach them. The Indians use strips of the stem for plaiting the tipitis or strainers used for squeezing out the poisonous juice of the mandioc root. [A. B.]

**DESMOPODIUM.** A subgroup of *Podium*.

**DESMOS.** In Greek compounds=anything bound to another or brought into close contact with it.

**DESMOSTACHYS.** A genus of *Teucriaceae*, founded on a climbing shrub from Madagascar, with alternate, ovate or lanceolate smooth leathery stalked leaves, and several slender spicate racemes growing out of each axil. The flowers are very small, bracteated, with a five-toothed calyx, five linear oblong thin petals, and five stamens. [J. T. S.]

**DESVAUXIACEÆ.** (*Centrolepidæ*, *Brittoniæ*.) A natural order of monocotyledonous plants with incomplete flowers, included in Lindley's glumal alliance. They are small tufted herbs with bristly leaves, and flowers enclosed in a spathe or sheath. Glumes one or two; pales either none or represented by one or two delicate scales; stamens one, rarely two; ovaries one to eighteen, attached to a common axis, distinct or united partially, one-celled, with a single stigma to each; ovules single orthotropical. Fruit consisting of one-seeded carpels, opening lengthwise; seed pendulous; embryo having a lens-like form. They are found in the South Sea Islands and in New Holland. There are about fifteen species described, and four genera, of which *Centrolepis* and *Aphelia* are examples. [J. H. B.]

**DETARIUM.** A genus of West African *Leguminosæ*, of which only one species is known. The four-lobed calyx, absence of petals, and rounded succulent fruit distinguish it from most genera; and from *Dialium* to which it is most nearly allied, it is readily recognised by having ten stamens, five of which are longer than the others. *D. senegalense* is a tree of twenty to thirty feet high, with pinnate leaves, having oval entire leaflets, and small white fragrant flowers

arranged in axillary panicles shorter than the leaves. The fruits are between oval and orbicular, slightly compressed, and about the size of an apricot. Underneath the thin outer covering there is a quantity of green farinaceous edible pulp intermixed with stringy fibres that proceed from the inner and bony covering which encloses the single seed. According to M. Richard there are two varieties of this fruit, one bitter, the other sweet. The latter is sold in the markets and prized by the negroes as well as eagerly sought after by monkeys and other animals. The fruits of both are so similar that the negroes often mistake the one for the other, and do not find out their error until after having tasted them. The bitter variety they regard as a violent poison. The wood of the tree is hard and resembles mahogany in colour. [A. A. B.]

**DEUTZIA.** A genus of *Philadelphaceæ*, consisting of shrubs, whose leaves are rough with star-shaped hairs. The flowers are handsome, arranged in panicles, with a bell-shaped calyx, five petals inserted beneath a disc which surrounds the top of the ovary, ten stamens inserted with the petals, the five between the petals longer than the others, the filaments flat, awl-shaped at the top or three-lobed, the middle lobe bearing the anther; ovary inferior, three to four-celled; styles three or four, thread-shaped, erect; stigmas club-shaped; capsule leathery, surmounted by the disc, bursting in the middle by three or four slits. *D. scabra* is a hardy shrub, whose clusters of white flowers give it a very ornamental character. Its leaves are used by polishers in Japan on account of their rigid star-shaped hairs; these latter, too, and especially those of *D. staminea*, are sought after by microscopists, as affording objects of great beauty. *D. gracilis* is a particularly elegant early-flowering green-house shrub. [M. T. M.]

**DEVEREA.** The generic name of plants belonging to the umbelliferous order, characterised by the fruit being round or ovate and covered with scales or hairs. The species are natives of Africa, usually of small size and of a bare rigid aspect, broom-like; hence named *Deverea*, after the 'goddess of brooms.' In the earlier stages the plants usually have small linear leaves; at more advanced periods of growth few of these remain, hence the peculiar habit of the species. [G. D.]

**DEVILLEA.** A genus of *Podostemaceæ*, comprising Brazilian herbaceous species, with hermaphrodite flowers unprotected by a bract; one stamen, whose anther opens inwardly; small globular stigmas; and smooth fruit, dividing by two unequal valves. *D. flagelliformis* has in its leaves somewhat the appearance of *Ranunculus aquatilis*. [M. T. M.]

**DEVIL IN A BUSH.** *Nigella*.

**DEVIL'S APRON.** The American name for the very broad form of *Laminaria sac-*

*charta*. Dr. Harvey says of the United States plant, 'numerous varieties, which perhaps demand future study, occur on the American coast. *L. Lannourouzi*, which has been sent me from Boston Harbour and from Newfoundland, looks almost like a species with its thick broadly-elliptical scarcely waved frond and its slightly-branching root.' The species, in fact, varies from one foot to six or ten feet in length, and from one to twelve inches in breadth. [M. J. B.]

DEVIL'S BIT. *Scabiosa succisa*; also *Chamaelirium luteum*, sometimes called *Helonias dioica*.

DEVIL'S GUTS. A vulgar name for the species of *Cuscuta* or Dodder.

DEVIL'S LEAF. *Urtica urentissima*.

DEVIL'S MILK. *Euphorbia Peplus*.

DEVIL TREE. *Alstonia scholaris*.

DEWAZ. The Caspian name for the grape Vine.

DEWBERRY. *Rubus coccineus*, and *R. canadensis*.

DEWEYA. A genus of the umbelliferous order, having five sharp tooth-like projections on the top of the fruit; the latter is oblong and oval, each half with five elevated ribs. The only species is perennial, herbaceous, a native of North America, with the leaves simply divided into pinnæ: the divisions large, ovate or heart-shaped, with numerous sharp teeth; the flowers pale-yellow. [G. D.]

DHAEE. The flowers of *Grislea tomentosa*, used in India, mixed with *Morinda*, for dyeing.

DHAK TREE. *Butea frondosa*, which yields *Butea kino*.

DHAL or DHOL. *Cajanus indicus*.

DHAMNOO. The timber of *Grewia elastica*.

DHAROOS. A Bengalee name for *Abelmoschus esculentus*.

DHENROOS. A Bengalee name for the fibre of *Abelmoschus esculentus*.

DHOONA. The balsamic resin of *Shorea robusta*.

DHOONA-TIL. The Cinghalese name for the balsam obtained from *Dipterocarpus*.

DHOOP. *Vateria indica*.

DHOORIA. An Indian name for worm-wood.

DHURRA DOURAH or DURRA. An Indian name for the grain-bearing *Sorghum vulgare*.

DI. In Greek compounds = two.

DIACHYMA. The green cellular matter of leaves.

DIACALPE. A beautiful eastern fern allied, on the one hand, to *Peranema* (the

*Sphaeropteris* of some authors), from which it is distinguished by having the globose involucre, which enclose the spore-cases, sessile instead of being stalked; and on the other to *Woodia*, from which it may be known by the hard texture of the Indusia, and by their irregular mode of bursting. *D. deparioides* is a herbaceous species, with finely divided decomposed fronds, and is found in Java and some parts of India. Two other species have been described, one from Java, the other from Madagascar, but little is known respecting them. [T. M.]

DIADELPHOUS. Consisting of two parcels or fraternities of stamens.

DIADENIUM *micranthum* is a stemless orchid about a span high, found growing on trees in Peru. The leaves are oblong-lanceolate, seldom more than two or three in number, and the small, rose-coloured flowers are arranged in a loose panicle. The anther is two-celled with two waxy pollen masses attached to the end of the caudicle which is dilated above, and furnished with two glands at the apex, whence the generic name. *Comparrhia* is the most nearly related genus, but that has two instead of one caudicle to the pollen masses. [A. A. B.]

DIAGNOSIS. The short character or description by which one plant is distinguished from another.

DIALIUM. A genus of leguminous trees found in tropical India, Africa, and America, and numbering about seven species. The chief distinguishing features of the genus are found in the flowers having but two stamens (most leguminous plants have ten), and in the fruits being round or slightly compressed, and containing an edible pulp surrounding the seeds. All have unequally pinnate leaves, and terminal panicles of small white or rose-coloured flowers. These have a five-parted calyx, and are usually destitute of petals; some flowers, however, are found with a solitary petal. *D. guineense*, the Velvet Tamarind of Sierra Leone, is a tree of about twenty feet high with slender branches, and pinnate leaves of five to seven smooth oval entire leaflets; the flowers are pale rose-colour; and the pod, about the size and form of a filbert, is covered with a beautiful black velvet down, while the farinaceous pulp which surrounds the seeds has an agreeable acid taste, and is commonly eaten. The fruits of *D. ovoideum*, a Ceylon plant, are sold in the bazaars; they have also an agreeable acid flavour. The wood of this plant is said to be strong, durable, and suitable for ornamental furniture. *D. floribundum*, a Brazilian species, has round smooth fruits about the size of a marble, containing one or two seeds surrounded with a pulp which has a taste and smell like that of currants. The Tamarind Plum of the East Indies, *D. indicum*, has a delicious pulp resembling that of the tamarind, but not quite so acid. [A. A. B.]

**DIALYPETALÆ.** Plants with distinct petals, in contradistinction to *Gamopetalæ*, which have the petals united into a single corolla. The term is a modern one proposed to be substituted for *Polyptetalæ*, which is more generally used in the same sense, although it signifies literally plants with many petals.

**DIALYPETALOUS.** The same as *Polyptetalous*.

**DIALYPHYLLOUS.** The same as *Polysepalous*.

**DIAMORPHA.** The name of a small crassulaceous North American herbaceous plant, with whorled branches, alternate cylindrical leaves, and small white flowers with four-parted whorls. The ovary consists of four carpels adherent at the base, but divergent at the top; the fruit is a four-celled capsule. [M. T. M.]

**DIANELLA.** A genus of *Liliaceæ*, containing herbs from Australia and Tropical Asia, distinguished by their fruit being berry-like, their stem leafy, the flowers perfect, the stamens inserted at the very bottom of the six-parted perianth, and the filaments incurved, thickened at the apex. They have fibrous roots, grass-like leaves, and paniculate blue flowers on drooping pedicels. The berries are blue, many-seeded. [J. T. S.]

**DIANTHUS.** The Pink. An extensive genus of *Caryophyllaceæ*, distinguished by having two styles, and a cylindrical calyx tube bracteated at the base. Most of the species are natives of Europe, temperate Asia, and the North of Africa. The leaves are often rigid, glaucous and grass-like; the flowers crimson or pink in more or less regular dichotomous cymes, sometimes reduced to fascicles or compact heads; in these latter the central flowers have no bracts at the base of the calyx tube, but in this case the lateral flowers, and in by far the greater number of species, all the flowers have two or more close-fitting scales or bracts, often like a small outer calyx. In Britain the following occur: *D. profler* and *D. Armeria*, both annuals with clustered flowers; and *D. plumarius*, or Pinksant's Eye; *D. Caryophyllus*, or Clove Pink; *D. carsius* and *D. deltoides*, all which are perennials with separate or solitary flowers. *D. Caryophyllus* is the original of the garden Carnations. *D. barbatus*, which has fasciculate corymbose flowers and broad leaves, is often seen in cultivation under the name of Sweet William. [J. T. S.]

**DIAPENSACEÆ** (*Diapensideæ*.) A small order of corollifloral dicotyledons, established by Lindley in 1830, and by him referred to his gottlandian alliance; and recently reconstructed by Dr. Asa Gray. Perennial herbs, sometimes suffrutescent, with alternate leaves, and pentamerous gamopetalous flowers. Calyx persistent; rotation quinquefidal; stamens adnate to and alternating with the segments of the corolla, the fila-

ments often dilated; ovary 3 (rarely 4) locular, style one, stigma naked subtrilobate; ovules numerous indefinite, placentas axillary; capsule loculicidal; albumen fleshy; cotyledons very short. As thus defined, the order includes *GALAX* and *Smertia*; which see, besides *Pycnanthera* and *Diapensia*, as when first established. The plants inhabit the northern parts of Europe and North America. [J. Br.]

**DIAPENSIA.** Two beautiful little Alpine plants are the only representatives of this genus, which gives the name to its family. The best known is *D. lapponica*, originally discovered in Lapland, but since found in many parts of Northern Europe, Asia, and America, where it has been gathered as far south as the White Mountains in New Hampshire: it is also found in Japan. *D. himalaica* was found by Dr. Hooker in Sikkim growing on rocks and in moist places in the sub-Alpine valleys at an elevation of 8,000 to 10,000 feet. Both are evergreen, and grow in dense tufts scarcely rising more than an inch above the ground. The stems are clad with closely imbricated spatulate, and entire leaves, which in *D. lapponica* are nearly half an inch long, and in *D. himalaica* much smaller; in the former the stems are terminated by a peduncle about an inch long bearing a solitary white bell-shaped flower about half an inch across, surrounded by a five-leaved calyx; the border of the corolla has five rounded flat lobes, and alternating with these lobes are five stamens which have their filaments dilated upwards. The Himalayan species has much the habit of the procumbent *Azalea* of the Scotch mountains, and its purple flowers with short stalks call to mind those of the opposite-leaved saxifrage. The flower-stalks continue growing after the flower withers, and when the capsule is ripe are frequently more than two inches long. The allied genus *Pycnanthera* is distinguished by having awned points to the anther-cells, while in *Diapensia* the anthers are awnless. [A. A. B.]

**DIAPHANOUS.** Transparent, or nearly so.

**DIAPHYSIS.** A præternatural extension of the centre of the flower, or of an inflorescence.

**DIARRHENA.** A genus of grasses belonging to the tribe *Festuceæ*, distinguished by the panicles of inflorescence being simple and contracted; the spikelets roundish, two to five-flowered; glumes two, unequal, acute, mucronate; stamens two or three; styles two, feathery. Only one species is described, *D. americana*, which has creeping stoloniferous roots, and erect simple stems, three to five feet high. [D. M.]

**DIASCIA.** A genus of *Scrophulariaceæ*, consisting of South African herbs, mostly annuals, very nearly allied to *Nemesia* and *Hemimeris*. They differ from the former in the corolla, which is flattened or cou-

cave, with two spurs or pouches at the base instead of one, and in the capsule, which is not flat; while from *Hemimeris* they are chiefly distinguished by their four stamens, all usually bearing anthers, the filaments of the lower ones curved round at the base so as to embrace the upper ones. There are about twenty species known.

**DIASPASIS.** A genus of *Goodeniaceae*, containing a single species, *D. filifolia*, a native of the south-west coast of Australia. This has an adnate calyx with five short teeth, a nearly regular salver-shaped rose-coloured corolla with a five-parted limb, and free included stamens. The peduncles are axillary and single-flowered; the leaves alternate and nearly terete. [R. H.]

**DIATEMELLA.** A genus of *Gesneraceae*, containing a single species from Costa Rica. It is a slender hairy herbaceous plant, with ovate serrate and petiolate leaves, and flowers in axillary racemes. The corolla is slightly oblique and ringent, and the limb bilabiate, with the upper lip two-lobed, and the lower one trifid. The four stamens are included, and with the rudimentary fifth are inserted on the base of the corolla. The capsular fruit is membranaceous. [W. C.]

**DIATEMMA.** A genus of *Gesneraceae*, containing thirteen species natives of South America. They are perennial stoloniferous scaly herbs with opposite leaves, and small flowers in axillary corymba. The calyx is adherent to the base of the ovary; the corolla is oblique, erect in the calyx, with a tube subcylindrical or increasing upwards, and a five-lobed spreading limb; the four stamens are included, the fifth rudimentary; the anthers are small and coherent. The ovary is surrounded by five elongate glands, and surmounted by a bilamellate stigma. [W. C.]

**DIATOMACEÆ.** A very distinct natural order of green-spored *Algae*, remarkable for the enormous quantity of silicx contained in their frond, and for their yellow-brown colour. The mode of increase so closely resembles that of *Desmidiaceæ*, that in this respect, we refer for information to that article. Their claims to a place amongst animals was even more strongly contested than in that order, but Mr. Raife's discovery of the formation of spores by conjugation in several genera has effectually put an end to controversy. The species are often attached by a slender peduncle when young, and in some genera this is repeatedly dichotomous. The joints often remain connected for a long time, separating in some instances alternately above and below so as to form a curious chain. When connected they form various shaped fronds, as linear, flabelliform, circular, &c.; but in a multitude of instances disarticulation takes place with the formation of each new individual. The separate joints which have received the name of frustules exhibit frequently a totally different outline when seen dorsally and laterally, and they are almost always adorned with deli-

cate streaks and other markings. In *Coscinodiscus* they form a disk with circular apertures like a colander. In many cases the frustules have distinct external apertures in the siliceous coat, without which it is not easy to see how there could have been a proper communication with the surrounding medium from which they must derive their nourishment. In consequence of the large proportion of silicx which they contain, the frustules are capable of retaining their form after all vegetable constituents have fled, and thus they are admirably adapted for preservation in a fossil state. Vast beds accordingly occur, many feet in thickness, consisting entirely of effete frustules, known under the name of Tripoli, and affording an admirable material for polishing, for which they are used extensively. 'The phonolite stones of the Rhine,' says Dr. Hooker, 'and the Tripoli stones, contain species identical with what are now contributing to form a sedimentary deposit, and perhaps at some future period a bed of rock extending in one continuous stratum for 400 measured miles. I allude to the shores of the Victoria barrier, along whose coasts the soundings examined were invariably charged with diatomaceous remains constituting a bank which stretches 200 miles north from the base of the Victoria barrier, while the average depth of water above it is 300 fathoms or 1800 feet. Vast quantities again occur in bed under the guise of a white powder, which is called mountain meal, and is actually mixed with flour in some parts of Sweden, though it is perfectly inert, and can serve merely to increase the bulk of the food, a circumstance of some importance where it is scarce.\* The walls of the frustules are so thin, and the little cells of silicx so light, that they are often wafted to great distances by the trade and other winds, so that species of remote regions may occasionally occur in a dead state in countries where they could not maintain their existence. *Diatomaceæ* form a large portion of the food of some of the lower mollusks, which in turn are preyed on by sea birds; and as the shells are capable of resisting digestion, they are found, frequently in great quantities, in the beds of manure which are collected for agricultural purposes under the name of guano. Many unique species have been obtained by travellers from the stomachs of fish, which sometimes afford an abundant harvest for the microscope. *Diatomaceæ* occur in all parts of the world, and abound amongst the ice and in the deep sea of polar regions. They probably are the plants above all others capable of enduring extreme degrees of cold without annihilation; while, on the contrary, several occur in springs of high temperature. The striae on the walls

\* Experiments in cattle-feeding show that the relative quantity of nutritious matter in food, independent of the bulk, is not the only point worthy of observation. The stomach must be properly filled, or, as it is termed in French, *lesté*, or the due effect of the nutriment will not be obtained.

are often so regular that the frustules form admirable tests for ascertaining the comparative merit of microscopes.

Though *Diatomaceæ* are for the most part free or only attached for a time, there are a few genera in which an enormous quantity of mucus is thrown out by the frustules, which accordingly, as in *Schizone-ma*, *Dickia*, &c., form variously shaped filiform or alveolar fronds. In *Cymbellæ*, a suborder, the quantity of siliceous is comparatively so small that the plants are more easily destructible than in the other sections. The peculiar motions in the genus *Bacillaria* have been noticed above. In many other genera motion has been observed, but it is now well known that even active motion is not incompatible with the nature of vegetables. For full information we refer to Mr. Smith's beautiful work on *Diatomaceæ*. [M. J. B.]

**DIBLEMMA.** The name of a Philippine Island fern, in which the sort are of two kinds: the first linear continuous, seated on a submarginal receptacle; the second roundish or oblong, and irregularly scattered. *D. samarensis* has simple fronds and uniformly reticulated venation, short free venicels being included in the unequal areoles. [T. M.]

**DICALYX.** The name given by Loureiro to a few Asiatic bushes which were described as belonging to the tea family. Modern authors have shown, however, that they are genuine species of *SYMPLOCOS*: which see. [A. A. B.]

**DICELLA.** A genus of Brazilian climbing shrubs belonging to the *Malpighiaceæ*. The calyx has five segments each provided with two glands at its base; the petals are stalked, unequal in size, and downy on the outside; the stamens are ten, united below into a tube, the anthers hairy; the ovary is two-celled, surmounted by two hook-like styles. Drupe woody, one-celled, one-seeded. [M. T. M.]

**DICENTRA.** A genus of *Fumariaceæ*, the *Dicentra* of De Candolle, afterwards changed to *Diclytra*. They are known by the two outer petals being spurred or bulging at the base, the seeds crested, and the capsule with two dry valves. The species are natives of the Northern Hemisphere, and are generally stemless herbs with ternately compound leaves, and succulent stems terminating in a raceme of large nodding flowers, which are white, rose-coloured, or purplish. The section *Eucapnos* has the outer petals merely bulging at the base, and the racemes compressed; while *Cucullaria* has the outer petals produced backwards into two long spurs at the base, and its racemes are simple. The two most common American species, which belong to the second group, have white flowers. *D. Cucullaria* is known in the United States as Dutchman's Breeches, from the shape of the spurred flower, and *D. canadensis*, which is fragrant, as Squirrel Corn. A stemless species from Virginia and North Carolina, with rose-coloured flowers, *D.*

*formosa*, is often cultivated in gardens; but the best known and most beautiful is *D. spectabilis*, from Northern China, which has a leafy stem, and flowers nearly an inch long, of a beautiful rose colour, with the narrow constricted inner petals white; the leaves are like those of the Mountain peony in miniature. [J. T. S.]

**DICERANDRA.** The name of a genus belonging to the labiate order, chiefly distinguished from its congeners by the presence of two straight and pointed appendages on the upper part of each stamen, hence the name, derived from Greek words which together signify 'two-horned stamens.' *D. carolinensis* is a small shrub, a native of the United States, having erect stems and narrow entire leaves. [G. D.]

**DICEROS.** A name successively given by different authors to species of *Artisanema*, *Linnophila*, and *Vandellia*.

**DICLEA.** A genus of orchids found growing on tree stems in the West Indies and the adjoining mainland. They are small tufted plants having short erect or creeping stems, thickly clad with small ovate-oblong or linear leaves arranged in a two-ranked manner, and solitary inconspicuous axillary greenish flowers. About a dozen species are known. [A. A. B.]

**DICHÆTA.** A genus of small annual Californian composite herbs, of which two species are known. They seldom exceed six inches in height, and are found on the margins of pools or in wet places. The stems and leaves are covered when young with loose white wool. The lower leaves are generally pinnatifid with linear segments, and the upper entire; and the yellow flower-heads are single on the ends of the stems. The genus is nearly allied to *Burrielia*, but differs in the pappus being composed of from four to eight oblong-obtuse scales, with generally two which are awl-shaped and awned. [A. A. B.]

**DICHASIMUM.** A name once given to an Indian fern which proves to be the same as the English *Lastrea Filix-mas palacæa*.

**DICHERANTHUS.** A genus of *Illecebraceæ* allied to *Pteranthus*. Small shrubs from the Canary Islands, with opposite or verticillate fleshy linear-cylindrical leaves, dilated and clasping at the base; and flowers in small dense compound corymbose cymes at the apex of the branches; calyx segments mucronate, hooked when in fruit; corolla none. [J. T. S.]

**DICHILIS.** A genus of slender erect or prostrate South African leguminous herbs, nearly related to *Argyrobolus*, but differing in the keeled petal being rather longer than the vexillum, and in the pods being swollen at intervals (torulose), not flat, and clad with silky hairs. The stalked leaves are made up of three narrow leaflets. The little yellow flowers are either solitary or racemed in the axils of the leaves, their calyx distinctly two-lipped, and the pod is smooth, narrow, and

inch or more in length. Three species are known. [A. A. B.]

**DICHLAMYDEOUS.** Having both calyx and corolla.

**DICHOGAMOUS.** When the florets of an inflorescence are of two separate sexes.

**DICHONDRA.** A genus of *Convolvulaceae* containing two species, one a native of the tropical and sub-tropical regions both of the Old and the New Worlds, the other found in tropical America. They are prostrate herbs with small flowers. The calyx five-parted; the corolla campanulate and deeply five-lobed; the ovary consisting of two distinct carpels with one ovule in each of the two cells. The two styles are distinct from the base, with thickened stigmas. [W. C.]

**DICHORISANDRA.** A genus of *Commelyneaceae* with the habit of *Tradescantia*, but with the filaments neither hairy nor dilated at the apex. They are Brazilian herbs, with lanceolate acuminate leaves, and racemose flowers, either terminal or produced from the base of the stem. [J. T. S.]

**DICHOSEMA.** There is a group of small leguminous West Australian bushes in which the stamens are ten in number and quite free, and the pods have their margins rolled inwards, so that they are imperfect or altogether two-celled, and a cross section of them would be somewhat like the figure 8. To that group *Dichosma* belongs. It differs from the others in having a very broad vexillum which is bilobed at the apex, and much longer than the wings; these in their turn being a little longer than the keel. There are about half a dozen species, all of them little spiny bushes seldom more than two feet high. The slender stems are clad with minute linear or oblong leaves generally arranged in parcels of three, and accompanied by slender spines which often exceed them in length. The flowers are small, yellow, or purple, solitary in the leaf-axils or arranged in short racemes. [A. A. B.]

**DICHOTOMIA** (adj. **DICHOTOMOUS**). Having the divisions always in pairs; a term equally applied to branches, or veins, or forks.

**DICHROCEPHALA.** A genus of Asiatic, African, and Australian *Compositae*, which differs from its near allies chiefly in the convex receptacle of the flower-heads. They are branching herbs, with oval coarsely toothed or lyrate sometimes pinnatifid leaves; the branches being terminated by panicles of nearly globular flower-heads, about the size of a small pea. The achenes are compressed, those of the outer florets without pappus, as those of the inner series with a pappus of one or two short hairs. Of the five species known, all are common weeds in the countries where they grow, and of no beauty. [A. A. B.]

**DICHYNCHOSIA.** A genus of *Cunoniaceae* from Celebes. A tree with opposite pinnate leaves, the few leaflets of

which are oblong ovate, coarsely serrated, with the under surface (as well as the branchlets and inflorescence) covered with stellate down. The stipules are large and kidney-shaped. The flowers grow in axillary panicles, which are much branched in a corymbose manner; the calyx five or six-parted, persistent; stigmas two, diverging; capsule two-beaked; seeds numerous, with a membranous wing. [J. T. S.]

**DICKIEA.** A curious genus of *Diatomaceae*, in which the frond assumes an ulvoid form, as it does a filiform in *Monema* and *Schizonema* and a globose in *Berkelia*. When the gelatinous element in these genera is removed, the frustules are found to be of precisely the same nature as those in genera where the gelatinous element is extremely reduced, or where it only tends to keep a quantity of frustules together in an irregular stratum. [M. J. B.]

**DICKSONIA.** A genus of noble mostly arborescent ferns of the polypodiaceous group, and typical of the section *Dicksonia*. Their stems are often thick and trunk-like, but sometimes decumbent. The fronds are large, generally decoupaned, and leathery, forming a noble tuft or crown; and the sori are globose or shortly oblong, transverse, and marginal, with a coriaceous indusium of two valves, of which the outer, formed of a lobe of the frond, is cucullate, and the inner usually smaller and less convex; the veins are free. *D. antarctica* is a very beautiful tree fern often seen in green-houses, having been freely imported from our Australasian colonies. Others occur in St. Helena, Brazil, Juan Fernandez, Columbia and Java. One pinnate species, *D. abrupta*, which is only found in Bourbon, has quite the aspect of a *Nephrolepis*. The sori are always more or less recurved from the plane of the frond. [T. M.]

**DICLESIMUM.** A one-seeded indehiscent fruit enclosed within a hardened perianth, as in the marvel of Peru.

**DICLIDANTHERA.** A genus of dicotyledons, founded on two Brazilian shrubs which are in many respects allied to *Sapoteae*. Differing, however, as it does in a slight irregularity in the flowers, in the curious two-valved anthers, and in the structure of the ovary, some eminent botanists have proposed associating it severally with *Polygalaceae*, *Hamamelidaceae*, or even *Ettneriaceae*. Benthams and Hooker regard it as being allied to the *Caryaceae*.

**DICLIDIUM.** A genus of plants belonging to the *Cyperaceae*. Only one species is described, namely, *D. ferax*, a native of South America. [D. M.]

**DICLIDOGARPUS.** A synonym of *Taxodermum*; which see.

**DICLIDOPTERIS.** A genus of polypodiaceous ferns belonging to the *Pleurogrammaeae*, having linear continuous sori, sunk in a deep oblique furrow on each side and near to the costa, towards which the opening is directed. The veins are

reduced to the costa, and the intermarginal receptacle parallel with it. The only species, *D. angustissima*, found in the Pacific Islands, is a very small plant, with narrow simple fronds. The genus is related closely to *Monogramma* and *Pleurogramma*. [T. M.]

**DICLIDOSTIGMA.** — cucurbitaceous plant of Cuba, with the aspect of *Bryonia*. Both calyx and corolla are five-cleft, the segments of the latter, in the male as well as in the female flowers, being rough and glandular: there are five stamens in three parcels with separate wavy anthers; in the female flowers there is a five-lobed glandular disk surrounding the base of the style, which latter is terminated by three stigmas, each of which is divided into two plates. The fruit contains six to nine seeds. [M. T. M.]

**DICLINOUS.** Having the stamens in one flower and the pistil in another.

**DICLIPTERA.** A considerable genus of *Acanthaceae*, containing nearly seventy species, dispersed over the tropical and subtropical regions of the New and Old Worlds. They are herbs with entire leaves, and with flowers in axillary clusters and short cymes, usually surrounded by four bracts, of which the outer two are the larger. The calyx consists of five sepals; the corolla is two-lipped, and the tube is so twisted that the upper entire or two-toothed lip becomes the lower; there are two stamens whose anthers have each two similar cells, but with the one inserted much below the other. [W. C.]

**DICLIS.** A genus of *Scrophulariaceae*, consisting of slender herbaceous creepers resembling in habit *Lénaria Cymbalaria*, and with very similar corollas, but the anthers have only one cell, and the capsule is nearly globular, opening loculicidally in two valves. There are three species known, all from south-eastern Africa or Madagascar.

**DICLISODON.** A name proposed for a curious genus of ferns, in which the sori occupy small projecting marginal teeth, and have scale-like covers. Hence it has been regarded as having a two-valved indusium, and as associating with the *Dicksonia*, the outer valve being described as a small rounded herbaceous projecting lobe of the frond; and the inner a proper indusium, larger than the lobe, membranaceous, and distinctly reniform, affixed by the sinus. The sori, though not stalked, project from the margin so as to resemble those of *Deparia*, but instead of a marginal cup, as in that genus, the involucre consists of the two valves lying flat in the plane of the frond; the veins are free. Some writers, however, regard the plant as a *Laetia* with exserted sori. *D. deparioides* is a very beautiful bipinnate fern, found in Ceylon. [T. M.]

**DICLYTRA.** The name of a genus of *Fumariaceae*, afterwards changed to *Dielstra*.

**DICOCCOUS.** Splitting into two coed.

**DICOLORATIO.** As petals are mere modifications of leaves, we need not be surprised if leaves themselves, though not in a state of transmutation to petals, occasionally exhibit vivid colours, especially in variegated plants. It does not appear, however, that coloured varieties grafted on those which are not coloured, communicate their colour in the same way in which variegated grafts affect the stock. The change of colour observable in leaves as autumn advances, appears rather to be a chemical than a vital action, and is owing, doubtless, to some change in the chlorophyll on which the healthy green tint of the leaves depends. The contents of the cells, like the cell walls themselves, have performed their office, and are therefore, like other inert bodies, subject to chemical changes, which would not affect them while their vital powers were active. [M. J. B.]

**DICOMA.** A genus of *Compositae* consisting of small undershrubs chiefly natives of the Cape of Good Hope, whence eleven species are enumerated, but represented also in India and Senegal. They have alternate entire or toothed leaves, and solitary heads of whitish flowers. The involucre is ———— patulate, equaling the disk, with the scales imbricate in many rows, coriaceous, entire, acuminate, often pungent; pappus in two or many rows. The name signifies 'twice-haired,' referring to the double pappus of the first described species, *D. capensis*. *Schagaueria* and *Xeropyppus* are now included. [J. Br.]

**DICORYNIA.** A genus of large trees of Brazil and Guiana belonging to the Leguminous family. Some attain a height of sixty, and a diameter of three to four feet. All have pinnate leaves a foot or more in length, made up of five or seven smooth leaflets. The branches are terminated by very large panicles of numerous white flowers, which are interspersed with fawn-coloured bracts. Each flower is about half an inch long, and composed of a calyx of three divisions; five unequal petals, the two exterior like the calyx leaves, the upper broadly orbicular at the point and narrowed below into a claw, and the two lateral obliquely orbicular and shorter; two stamens with broad and thick filaments of unequal length; and an ovary crowned by a curved style. The pods are obliquely oval, thin, about one and a half inch long, and contain one or two seeds. Four species are known. [A. A. B.]

**DICORYPHE.** A genus belonging to the order of witch-hazels. The name indicates one of its obvious characters, viz, the presence of two horn-like appendages on the upper part of the fruit. *D. stipitata* is a native of Madagascar, having slender branches with oblong, entire, and shortly-stalked alternate leaves, and below

each, a pair of unequal heart-shaped appendages, the stipules. [G. D.]

**DICOTYLEDONOUS.** Having two cotyledons.

**DICOTYLEDONS, DICOTYLEDONEÆ.** Plants having two seed-leaves or seedlobes, which are called cotyledons. This is one of the primary divisions or classes of the vegetable kingdom, including about 7,000 known genera, and about 70,000 known species of flowering plants. The class also receives the name of *Ezogonæ* or *Exogonæ*, from the structure of the stems. The plants in this great class have spiral vessels; their stems are formed by additions externally in the form of zones or rings; stomata or pores exist in the leaves, which have a reticulated or netted venation. The plants have stamens and pistils, either in the same or in different flowers. The symmetry of the flowers is represented by five or two, or multiples of these numbers. The ovules are contained in an ovary, or more rarely are naked; and the embryo has two, sometimes more, cotyledons.

In De Candolle's system this class of Dicotyledons is divided into four sub-classes:—1. *Thalamifloræ*, petals distinct; stamens hypogynous; 2. *Calyctifloræ*, petals distinct or united; stamens perigynous or epigynous; 3. *Corollifloræ*, petals united; stamens usually attached to the corolla, which is hypogynous; 4. *Monochlamydeæ*, including *Gymnospermeæ*, a calyx only, or no floral covering. Lindley divides the class into four subclasses: 1. *Dicotyles*, those plants which have separate staminate and pistillate flowers. Those which have stamens and pistil in every flower are divided into—2. *Hypogynous*, stamens not adhering either to calyx or corolla; 3. *Perigynous*, stamens adhering to either calyx or corolla; and 4. *Epigynous*, stamens, calyx, and corolla, all adhering to the side of the ovary. Gymnogens, or plants with naked seeds, represent a separate class according to Lindley. The age of Dicotyledonous trees can be computed by counting the number of annual concentric rings of wood. [J. H. B.]

**DICORÆA.** Herbaceous plants, natives of Madagascar, &c., constituting a genus of *Podostemaceæ*, characterised by hermaphrodite flowers unprotected by a bract; monadelphous stamens; and ribbed fruit opening by two equal valves. [M. T. M.]

**DICRANODNUM.** *Gymnogramma leptophylla*.

**DICRANOGLOSSUM.** A genus of polypodiaceous ferns of the group *Tantidea*, in which the sori are naked, linear, continuous, and submarginal as in *Tantopsis*; but the veins, instead of being straight and free, or combined by the transverse receptacle, describe a series of simple elongated arcs, each one uniting with the next, and thus forming a continuous irregular curved sub-marginal receptacle to which the spore cases are affixed. *D. subpinnatifidum*, a South American and West

Indian plant, with furcately-lobed fronds, is the only species. [T. M.]

**DICRANOLEPIS.** A genus of thymelaeaceous plants, the flowers of which have a salver-shaped perianth with a five-parted limb, and ten scales inserted in its throat; stamens ten, attached to the perianth; ovary stalked, with a cup-like disk at the base, one-celled, containing a single pendulous ovule. There is only one species, *D. disticha*, which grows at Sierra Leone: a shrubby plant with distichous leaves, and solitary axillary flowers. [J. H. B.]

**DICRANOPTERIS.** A synonyme of *Gleichenia*; also applied by some writers to a section of *Polypodium*.

**DICRANOSTIGMA.** A genus of *Papa-veraceæ*, represented by a plant indigenous in the Himalayan mountains. It has numerous radical pinnately-lobed leaves covered with short hairs; the stems are about a foot in height, and bear at the top two or three golden-coloured flowers, with a flask-shaped ovary, surmounted by thickened stigmas with two erect awl-shaped arms alternating with the placentas. It is now united by its authors (Hooker and Thomson) with Nuttall's North American genus *Seytophorum*. [M. T. M.]

**DICRANUM.** A large and important genus of acrocarpous mosses, distinguished by the unequal cernuous capsule, the hood-like calyptra, rostrate lid, and single peristome consisting of sixteen equidistant teeth which are confluent at the base, and split half way down or more into two unequal portions, the medial lobe being continued to the base, and occasionally perforated. *Leucobryum* is distinguished by the peculiar structure of the leaves, and their consequent pallid hue. The species, from the different habits which they assume, are distributed into several distinct sections. They grow variously on rocks, or on the ground, or more rarely on the trunks of trees. Some of them, as *D. scoparium*, are amongst the larger mosses, and remarkable for their long and often curved leaves, while others are minute. It is observed by Wilson, in his *Bryologia*, that in several of the larger species, which have the stem covered with a dense layer of radical fibres, the male plants appear to be replaced by minute bulbs, nestling among the fibres; and this is all that is known of the male inflorescence of certain species; but in *D. scoparium* the inflorescence may sometimes be traced from these radicular gemmæ up to the perfect development of male plants. A somewhat analogous process is observable also in a few species of *Lyptrum*. [M. J. B.]

**DICTAME BLANC.** (Fr.) *Dictamnus albus*. — **DE CRÈTE.** *Origanum Dictamnus*.

**DICTAMNUS.** A small genus of *Rutaceæ*, found in southern Europe, Asia Minor, &c. *D. Fraginella* and *D. albus* are both cultivated in gardens for their fragrant leaves, as well as for the hand-

some appearance of their flowers. They are perennial plants with unequally-pinnate leaves, the main stalk between the four or five pairs of leaflets being winged and leaf-like. The inflorescence, as well as the outer parts of the flowers themselves, is covered with glands secreting a resinous or oily matter, so volatile, that their surrounding it becomes inflammable in hot weather. The calyx has five sepals, the two lowermost of which are longer than the rest; the five petals, which are stalked and inserted into the stalk bearing the ovary, are of unequal size, the four upper ones erect, and the lowest one bent downwards; the stamens are ten, bent downwards; the five ovaries are placed on a short stalk, each one-celled. The fruit consists of a capsule, the constituent carpels of which are confluent below but separate above, and when mature burst each into two pieces: they contain two or three seeds. [M. T. M.]

**DICTYANTHUS.** A genus of *Asclepiadaceae*, containing twenty species, natives of Central America. They are twining undershrubs, with cordate membranaceous leaves on long petioles, and one or two-flowered peduncles. The corolla is campanulate, spreading, and five-cleft, and the staminal crown consists of five small lobes adnate to the tube; the stigma is fleshy with five prominent angles, and very small glandular corpuscles. [W. C.]

**DICTYDIUM.** A beautiful genus of *Fungi* allied to *Cribbaria*, but distinguished by the outer coat of the peridium disappearing so the very base, and leaving behind a beautiful net-work. In *D. umbellatum*, which is not uncommon on decayed fir stumps, the peridium is deeply umbilicate, and looks like an elegant balloon. [M. J. B.]

**DICTYMIA.** *Dictyopteris*.

**DICTYOCALYX.** Creeping pubescent herbs, allied to *Nicotiana*, but constituting a distinct genus of *Solanaceae* or *Atropaceae*, characterised by the presence of a cylindrical five-lobed calyx, the tube of which becomes distended after the expansion of the corolla, and is marked by a network of prominent veins. The corolla is membranous and funnel-shaped. [M. T. M.]

**DICTYOCLINE.** A genus of interesting hemionitoid ferns, which grow in India and China. *D. Griffithii*, found in Assam and Khasya, is a coarse herbaceous pinnate fern, with three or four pairs of pinnae, and having the sori reticulated between the primary pinnate veins, which transversely anastomose so as to form two or three series of roundish hexagonal areoles between them. The aspect of the plant approaches that of some of the larger species of *Aspidium*. [T. M.]

**DICTYOGENS.** (*Dictyogena*.) A sub-class of monocotyledons or Endogens according to Lindley. The plants are characterised by having net-veined in place of parallel-

veined leaves, which usually disarticulate with the stem. The woody matter on the rhizomes of the plant is often disposed in a circular wedge-like manner. The name is derived from the Greek word *dictyon*, a net. This subclass includes *Dioscoreaceae* or *yams*, *Smilacaceae* or *sarsaparillas*, and *Trilliaceae*, *Rozburghiaceae* and *Philistaceae*. Some *Araceae* and *Liliaceae* have, however, net-veined leaves. [J. H. B.]

**DICTYOGLOSSUM.** A genus of acrostichoid ferns, now called *Hymenidium*.

**DICTYOGRAMMA.** A genus of polypodiaceous ferns, found in Japan and the Feejees, and belonging to the group *Hemionitideae*, with naked linear reticulated sori, among which *Dictyogramma* is distinguished by having the primary veins arcuate so as to form costal areoles, and the venules reticulated, except those of the margin, which are free. The sori are narrow, linear, and sub-parallel, the lines sparingly united towards either end. The fronds are pinnate and somewhat leathery, with a few large pinnae. *D. japonica*, the typical species, is, as its name implies, found in Japan. *D. elongata*, from the Feejees, is the same fern which has been called *Syngamma pinnata*. The name has been used in place of *Selaginæ*. [T. M.]

**DICTYOLOMA.** A genus of Brazilian trees belonging to the *Simarubaceae*. The flowers are unisexual; calyx minute five-parted; petals five, sharply-pointed, or prolonged into a linear appendage; stamens five, attached below to a two-cleft scale. In the female flower there are five ovaries, five styles, and a five-toothed stigma. [M. T. M.]

**DICTYOPTERIS.** A genus of ferns belonging to the reticulated division of the *Polypodiaceae*, and comprising a few species found in the East and in Australia. They have either simple or bipinnate fronds, sometimes of large size; and dot-like naked sori, which are seated at the confluence of several veinlets (compital). The areoles of the reticulated veins are without free included veinlets, which, together with their uniformly reticulated, not confluent-anastomosing venation, separates them from all other genera of ferns with netted veins, and naked dot-like sori. [T. M.]

**DICTYOSTEGIA.** A genus of *Burmanniaceae*, consisting of a very few species from tropical America, all small slender leafless annuals, with very small flowers in a terminal cyme or head. They grow on rotten leaves in damp shady woods, and differ from *Burmannia* chiefly in their capsules opening by lateral pores.

**DICTYOTA.** A small genus of dark seeded *Algae*, with thin flat ulva-like forked fronds, producing spores in little superficial disks. The species are of an olive-green, and are widely diffused in either hemisphere. *D. dichotoma* is one of the commonest *Algae* on our coast, and assumes a great variety of forms as regards the length, breadth, and division of its fronds.

The development of the frond is curious, each division ending in a 'single cell by the constant division of which at its lower side the other cells of the frond are formed, the terminal cell being then continually pushed onwards.' This is the same mode of growth as that which obtains in exogenous stems. [M. J. B.]

**DICTYOTÆ.** An order of dark-seeded *Algae* with superficial spores or cysts, disposed in definite spots or lines. The fronds are sometimes flat, sometimes thread-like, and occasionally branched and tubular. In *Hydroclathrus* it is pierced with large holes. Some beautiful *Algae*, as *Padina*, *Zonaria*, *Hatieria*, belong to this order, which has representatives in every part of the world, but very few are found in high latitudes. *Padina pavonia*, the turkey feather laver, is common in warm countries, but extends to our own coasts as far as lat. 51°, though in North America it does not pass farther than lat. 25°. In *Cutleria* there is reason to believe that true spermatozooids are produced; but in some other genera, as *Stelophora*, two kinds of fruit occur, the one of which produces large, the other small zoospores, both of which have lash-like appendages. The cysts, which produce the large zoospores, are called *Trichosporangia*; those which produce the smaller, *Oosporangia*. [M. J. B.]

**DICTYOXIPHUM.** A genus of poly-podiaceous ferns related to *Lindsaea*, from which it is distinguished in the first place by its compoundly-reticulated veins having free included veinlets in their areoles; and in the second, by its indusium exceeding and being inflexed over the margin of the frond. The fronds are simple, narrower in the fertile parts, and the sori are linear continuous and marginal, with the indusium opening outwardly. There are only a couple of species, which are found in Panama and New Grenada. [T. M.]

**DICYPELIUM.** The name of a Brazilian tree of the laurel family. The flowers are dioecious. The male flowers are not described, but the female ones have a six-parted perianth; twelve barren stamens in four rows, the outermost petal-like, the innermost small and scale-like, the intermediate ones glandular. The fruit consists of a one-seeded berry, surrounded by the thickened fleshy perianth, which, with the sterile stamens, is persistent. The bark of *D. caryophyllatum* furnishes Clove Cassia. [M. T. M.]

**DICYRTA.** A genus of *Gesneraceæ*, containing a single species, a native of Guatemala. It is a perennial stoloniferous herb, with opposite leaves on long petioles, and solitary axillary flowers, the small corollas of which have a slightly-curved tube and an equally five-lobed limb. There are four didynamous stamens, with the rudiment of a fifth, inserted at the base of the tube. The disk is fleshy five-lobed; the stigma capitate, depressed. [W. G.]

**DIDERMA.** A genus of myxogastrous

*Fungi*, characterised by a double peridium, of which the outer is quite smooth and crustaceous; the inner delicate and attached to the straggling hairs amongst which the spores are seated. In some species the peridium bursts by regular radiating fissures, so as to look like a little flower, while in others it is ruptured irregularly. One of the most common species, *D. vernicosum*, is characterised by its obovate shining chestnut-coloured outer peridium. It is common in woods, on mosses, twigs, &c., and is often very conspicuous. The flower-like species are by no means common. The genus is found more or less frequently in all temperate regions. [M. J. B.]

**DIDICLIS.** *Selaginella*.

**DIDISCUS.** A genus of umbellifers, characterised by the fruit being very much flattened laterally, each half with five ridges, the middle ridge most prominent. The name of this genus is intended to indicate the double disk-like fruit. The species are herbaceous and natives of Australia. *D. cernuus* is a showy plant, covered with hairs; its leaves three-parted, each division again subdivided; its flowers blue. The fruit when mature is covered with small tubercles. Another species, *D. albiflorus*, has no hairs, and the flowers are white. [G. D.]

**DIDISMUS.** A genus of *Cruciferae*, with pods breaking across into joints which have one or two seeds in each, the uppermost joint ending in a striated beak, the lower one truncate at the apex. Flowers white or yellow. The species occur in Greece, Syria, and N. Africa. [J. T. S.]

**DIDYMIUM.** A genus of myxogastrous *Fungi*, distinguished by the outer coat of the peridium being scurfy, mealy, scaly, tomentose, &c., and bursting irregularly. The species are numerous and sometimes beautiful. One of the most common is *D. cinereum*, which occurs everywhere, and is easily known by its stemless cinereous peridium, and the snow-white flattish hairs amongst which the dark spores are dispersed. The genus belongs essentially to temperate climates. [M. J. B.]

**DIDYMOCARPUS.** A genus of *Cyrtandraeæ*, containing fully thirty species, natives of India. They are caulescent or stemless herbs or undershrubs, with the leaves serrate or crenate petiolate, those on the stem being opposite or rarely alternate; the flowers blue or white, in cymes; the calyx five-cleft; and the corolla funnel-shaped and unequally five-lobed. There are four stamens, two of which only are generally fertile; the long capsule bursts longitudinally, and contains many naked sessile pendulous seeds. [W. G.]

**DIDYMOCHETON.** A genus of *Melastomaceæ* trees, now united with *Diospyrum*, natives of the Moluccas. They have soft compound leaves, and flowers in axillary spikes or heads. The corolla has five linear petals, attached below to the tube of the stamens,

which is divided at the top into ten lobes, and contains within it ten anthers. The ovary is sessile, five-celled, surrounded by a gourd-shaped five-lobed disk; and the fruit is berry-like. [M. T. M.]

**DIDYMOCHLÆNA.** A genus of poly-podiaceous ferns, having indusiate sori of an oblong form attached longitudinally along its centre to a crest-like elevation of the receptacle, and free all round the margin; besides which the veins are free. *D. lunulata* is a fine South American arborescent fern with bipinnate fronds, the articulated pinnules of which are dark green, coriaceous, and shining. *D. dimidiata*, a South African plant, differs in having ecostate pinnules. [T. M.]

**DIDYMOGLOSSUM.** A division of the genus *Trichomanes*, in which the funnel-shaped involucre are two-lipped instead of truncate at the mouth, which is, in fact, an approach towards the two-valved involucre of *Hymenophyllum*. The group is considered by some writers to form a distinct genus. [T. M.]

**DIDYMOTHECA.** A genus of *Phytolaccaceæ*, from Tasmania. A smooth-branched undershrub with scattered linear semicylindrical leaves and axillary divisions; flowers on short stalks; the perianth four-lobed, two of the lobes larger than the others. [J. T. S.]

**DIDYMOUS.** Double; growing in pairs, as the fruit of umbellifers.

**DIDYNAMOUS.** Having two stamens longer than the two others.

**DIEFFENBACHIA.** A genus of arads, consisting of about fifteen species, all inhabitants of tropical South America and the West Indian Islands, where they flourish in moist shady places in the woods. Their stems are fleshy, and vary from two to six or eight feet long, partly lying upon the ground and partly erect, the erect portion bearing the greatest number of leaves. The leaves have fleshy foot-stalks, the lower part of which expands and forms a sheath round the stem; they are generally of an oblong form; in most species they are green, but some are marked or variegated with white or yellowish irregularly shaped spots, and all have numerous veins diverging from the midrib, and running parallel with each other until near the margin, where they curve upwards and unite. The spadix or flower spike is enclosed in a green or yellowish spathe, which does not wither like that of some allied genera, but remains fresh until the fruit is ripe; the lower part of the spike bears female flowers only, each consisting merely of an ovary surmounted by a stalkless stigma, and surrounded by from two to four rudimentary or imperfect stamens; the upper part is free and thickly covered with male flowers only.

*D. seguina* has acquired the name of Dumb Cane in the West Indies, in consequence of its fleshy cane-like stems rendering speechless any person who may happen

to bite them, the juice of the plant being so excessively acrid as to cause the mouth to swell, and thus to prevent articulation for several days. It is said that the West Indian planters were formerly in the habit of punishing their refractory slaves, by cruelly forcing them to bite a piece of this plant; and accidents have occasionally occurred with it in this country, where, however, it is only to be found growing in the hothouses of the curious. The negroes in the West Indies make an ointment for rubbing dropsical swellings, by boiling the juice of the plant in hog's lard; and a physician in the reign of Charles II. recommended the juice to be administered internally as a cure for dropsy, but it is so excessively acrid that it is almost impossible to swallow it. Notwithstanding the acidity, however, a wholesome starch has been obtained from the stem. The plant grows from six to eight feet long, and has a stem an inch and a half thick, bearing green leaves about ten inches long by four broad. When the leaves are pulled away the stem has a cane-like appearance. [A. B.]

**DIELLIA.** *Schizoloma*.

**DIELYTRA.** The names sometimes given to a very handsome genus of *Fumariaceæ* made familiar in gardens by the beautiful Chinese perennial called *D. spectabilis*. It was originally written *Didytra*, and is now referred to *Diondra*. [T. M.]

**DIENIA.** A small genus of terrestrial orchids, the species of which are found in the Himalayas, Siberia, and Mexico. They seldom exceed a foot in height; the stems in some being furnished with one leaf, in others with several. These are membranaceous, plaited, and usually ovate or ovate-lanceolate in form. The flowers are minute, green or yellowish, and disposed in slender erect spikes.

The four pollen masses are collateral (oooo), while in the nearly-related British genus *Malaxis* they are incumbent (88). *Microstylis*, also nearly related, has the lip at right angles to the column instead of parallel with it, as in *Dienia*. [A. A. B.]

**DIERVILLA.** A genus of caprifoliæ, distinguished from the honeysuckle and others allied to it, by its funnel-shaped three-cleft corolla, and one-celled fruit. The name was assigned by Tournefort in compliment to Dierville, a Frenchman, who discovered a species in Acadia, and sent it to that botanist. The species are erect shrubs, natives of North America and of Japan. That best known in cultivation is *D. canadensis*, a shrub from three to four feet high, with the leaves shortly stalked, smooth, sharply ovate, the edges serrate; the flowers are yellow and appear in early summer. In its wild state it is widely distributed in Canada, and is found about Hudson's Bay and on part of the Rocky Mountains.

Those which are natives of Japan are reported by Siebold, in his account of the plants of that country, as notable on account of the beauty of their flowers. These

showy eastern species are the *Weigelas* of our modern gardens. [G. D.]

**DIFFUSE.** Spreading widely.

**DIGITALIFORM.** Like campanulate, but longer and irregular, as the corolla of *Digitalis*.

**DIGITALIS.** A genus of *Scrophulariaceae*, represented in this country by the well-known Foxglove; which is the badge of the Farquharsons. The genus consists of several species, which are biennials or perennials, with flowers having a calyx deeply divided into five unequal segments; an irregular tubular corolla, the tube of which is distended in the middle, the limb four or five-lobed, the lowest lobe the longest; four concealed stamens; and the fruit a capsule opening by two valves.

*D. purpurea*, the common foxglove, is a well-known ornament of woods and roadsides in this country and the central parts of Europe. It has an erect stem three to four feet high, marked with a few longitudinal ridges and covered with greyish down; the leaves are alternate, ovate-lanceolate or oblong, covered with down, especially on the under surface, their margins crenate or divided into small rounded lobes, and the base tapered gradually into the leafstalks. The raceme is at the extremity of the stem, and consists of a number of flowers each protected by a bract, and all drooping on one side of the stem; the corollas are irregularly bell-shaped, and upwards of an inch in length, and of a pinkish-purple colour, marked in the interior with circular dark spots, which are interspersed among a number of delicate light-coloured hairs. This plant from its stately beauty is cultivated in shrubberies and gardens, where likewise a variety with white flowers may be frequently observed. In cultivated plants there frequently occurs a malformation, whereby some one or two of the uppermost flowers become united together, and form an erect, regular, cup-shaped flower, through the centre of which the upper extremity of the stem is more or less prolonged. All parts of this plant possess powerful medicinal properties, which are due to an extremely poisonous substance called *digitalis*. In medicine the leaves are the parts used, in the form of tincture and infusion. The effects of this drug are various and remarkable; that most frequently observed is a lessening of the force and frequency of the pulse. This occasionally takes place to a dangerous degree, and more than one instance is recorded, of a patient under the influence of this medicine, having died immediately on making a sudden effort to change his posture. The heart, enfeebled by the drug, has been unequal to the fulfilment of its functions under the increased requirements made upon it by the change in position. Hence, although it may be, and is sometimes used in large doses with impunity, its action must always be watched with great care, the more particularly as occasionally when employed in small but

frequently repeated doses dangerous symptoms accrue. Foxglove likewise acts as a diuretic, and in large doses causes vomiting, purging, and fainting. It is now most frequently employed in certain cases of dropsy and of heart disease with great benefit, though its use demands care and vigilance on the part of the practitioner. Lately it has been recommended in large doses in delirium tremens.

Several other species are grown in gardens, such as *D. grandiflora* and *D. lutea*, with yellow flowers, and *D. ferruginea* with brown flowers, but none rival our indigenuous foxglove in beauty, though they may do so in their poisonous qualities. [M.T.M.]

**DIGITARIA.** A genus of grasses belonging to the tribe *Panicæ*, distinguished by the inflorescence being in fingered spikes; spikelets in pairs, on one side of the flattened rachis, awnless, one-flowered with an inferior rudiment of a second; seed invested with the hardened pales. This genus is nearly allied to *Panicum*, under which all the species are described by Steudel. They are mostly natives of the middle and south of Europe, one, *D. humifusa*, reaching to the southern counties of England. [D. M.]

**DIGITATE.** When several distinct leaflets radiate from the point of a leaf-stalk.

**DIGITINERVED.** When the ribs of a leaf radiate from the top of the petiole.

**DIGITUS** (adj. **DIGITALIS**). The length of the Index finger.

**DIGLOTTIS.** A name applied to a Brazilian shrub of the rue family, characterised by its bell-shaped calyx; its corolla of five partially united petals; its five stamens, three of which are sterile and adherent to the tube of the corolla, while the two fertile stamens have flattened filaments, hairy at the top, and anthers whose connectives are prolonged into acute hairy strap-like processes; ovaries five. [M. T. M.]

**DIGRAMMARIA.** A genus of polypodiaceous ferns proposed by Presl, and figured by him in his *Tentamen Pteridographiæ*, but somewhat doubtful as to its identity, no fern with indusia such as he describes being known to possess venation such as he figures. Some regard *Calopteris andigua* as the plant intended by Presl; while others consider it to be the plant he afterwards named *Heteropontium*, which latter view we adopt. This fern has linear oblong naked sori, borne on the two branches of the forked veins, and looking like double lines of spore-cases united below; hence appropriate to the name. The veins too are arcuate, forming costal areoles, with free venules. [T. M.]

**DIGRAPHIS.** *Phalaris*.

**DIKA.** *Iringia Bartschii*, the seeds of which furnish a kind of grease analogous to the butter of *Cacao*.

**DILIVARIA.** A small genus of *Ascomaceæ*, containing probably not more than three species, erect shrubs, natives of

India and Africa. They have entire or generally spinose and dentate leaves, and showy bracteate flowers in leafless spikes; the corolla consisting of a single three-lobed lip enclosing four didynamous stamens, with one-celled anthers, the margins of which are ciliated. [W.C.]

DILL. *Anethum graveolens*.

DILLENIACEÆ (*Dilleniaceæ*). A natural order of thalamifloral dicotyledons included in Lindley's ranal alliance, consisting of trees, shrubs, or undershrubs with exstipulate alternate leaves; five persistent sepals in two rows; five deciduous imbricated petals; stamens more than twenty, often turned to one side. Fruit consisting of two or five distinct or united carpels; seeds surrounded by an aril; albumen homogeneous. There are about thirty known genera and 230 species. They are found chiefly in Australia, India, and Equinoctial America. They have astringent qualities. Some are large timber trees. *Dillenia speciosa* is an Indian tree with showy flowers and an edible acid fruit. There are two suborders: 1. *Dilleneæ*, connective of the anthers equal or narrow at the point, found in Asia and Australia; 2. *Delmeæ*, connective of the anthers dilated at the point, found chiefly in America. Illustrative genera: *Dillenia*, *Candollea*, *Delima*, and *Tetracera*. [J.H.B.]

DILLENIÆ. The species of this genus of dilleniads are handsome lofty trees inhabiting dense forests in India and the Malayan Peninsula and Islands, one only reaching as far as the base of the Himalayan mountains. They have large alternate generally oval or oblong leaves, strongly marked with parallel veins running from the midrib to the margin, where they form the points of sharp teeth. The flowers, which are frequently large and showy, have five fleshy concave sepals, and five white or yellow petals, the sepals increasing in size after flowering and eventually closely covering the ripe fruit. The stamens are very numerous, and arranged in several series round the pistil, those composing the inner rows facing outwards, while the outer ones face inwards, the anthers opening by pores or holes at the top. The fruit consists of from five to twenty cells (or carpels) growing together round a fleshy centre, and surmounted by as many radiating styles; each cell containing numerous seeds, surrounded by a gelatinous pulp.

*D. pentagyna* is common throughout the peninsula of India, Birman, and Malaya, and forms a handsome forest tree, with a broad spreading head. Its leaves are of extraordinary size, averaging from one to two feet long, but in young trees sometimes as much as four or five feet; they are pointed at the top, and gradually taper from the middle to the base, the edges being either toothed or wavy. The flowers are yellow, about an inch in diameter, and produced in clusters upon the naked branches before the appearance of the

leaves; they have only ten stamens and five styles. According to Dr. Cleghorn, it is probable that this tree, and not the *Calophyllum inophyllum*, as generally supposed, furnishes the valuable poon spars used for Indian shipping.

*D. speciosa* is also a very handsome tree, growing about forty feet high, and commonly cultivated in India on account of its ornamental appearance. It is found in all parts of tropical India, as well as in the Malayan Islands and peninsula. The leaves are from ten inches to a foot in length seated upon broad foot-stalks; and the flowers are produced at the same time as the leaves, which are of great size and beauty, measuring, when fully expanded, as much as nine inches in diameter; the petals white and contrasting with the bright yellow stamens, which are extremely numerous, and form a dense globular mass in the centre of the flower, with the stigmas radiating like a white star upon the summit. The fruit is about three inches in diameter, enclosed in the swollen and fleshy calyx, which, as well as the fruit, is edible but very acid, and is also said to be slightly laxative. The natives in India use it in their curries or for making jelly, and the acid juice sweetened with sugar forms a cooling fever drink. The hard tough wood, also, is used for making gun-stocks. The fruits and calices of another species, *D. scabrella*, are likewise used in the same way as those of the last species; and the Chinese employ a decoction of the leaves of *D. retusa*, for cleansing foul ulcers. [A.S.]

DILL-SEED. The name applied by Ben-  
tham to *Anethum graveolens*.

DILLWYNIA. A genus of pretty yellow-flowered juniper-leaved bushes of the leguminous family, numbering about a dozen species, three of which are found in Tasmania, and the remainder in the southern and western parts of Australia. The leaves have no stipules, the pedicels are furnished with little bracts, and the vexillum or upper petal is broad. These characters taken together serve to distinguish the genus from *Pultenea*, to which it is most nearly allied. In a few the leaves are more like those of a heath than a juniper; they are either smooth or slightly rough, and sometimes covered with a grey pubescence. The little yellow pea-flowers, scarcely half an inch across, make up for their minuteness by their great profusion; they are arranged in axillary or terminal clusters which seldom exceed the leaves. The minute pods, unless carefully searched for, will be readily overlooked; they are nearly oval, ventricose, and one or two-seeded.

A number of these plants have long been in cultivation in greenhouses, and richly repay the attention of the cultivator in the great profusion of their yellow blossoms. One of the best is *D. ericifolia*, which has solitary or twin bright yellow flowers, arranged so closely towards the ends of the branches as nearly to hide the leaves: this plant is sometimes called *D. floribunda* from the abundance of its

flowers. In *D. parvifolia* the leaves are scarcely a quarter of an inch long, and the flowers are in terminal clusters of four or five, of a pale-yellow colour, with the standard marked at the base by a reddish tint. One of the most desirable species, from its flowering while not more than eight inches high, is *D. scabra*, which has linear leaves about half an inch long covered with minute tubercles; this is remarkable in having stalked corymbs of bright nearly scarlet flowers at the ends of the twigs. The genus is named after L. W. Dillwyn, Esq., an English botanist. [A. A. B.]

**DILOPHIA.** A genus of *Cruciferae* from Tibet, a small annual with spatulate leaves, and the flowering racemes contracted into umbels; pouch tuberculated with a partition, having a wide opening through it. [J. T. S.]

**DIMIDIATE.** When one half of an organ is so much smaller than the other as to seem as if missing; hardly different from oblique except in degree; also slit half-way up.

**DIMIDIATO-CORDATE.** When the larger half of a dimidiate leaf is cordate.

**DIMORPHANTHUS.** A genus belonging to ivywort. The name means 'two-formed flower,' indicating that there are some flowers which are in every respect perfect and produce fruit, and others in which no perfect seeds are formed. The flowers of the first kind have the calyx oblong and bell-shaped, or ovate and pentagonal; the styles or appendages on the upper part of the seed-vessel are more or less spreading; in the other flowers the tube of the calyx is in the form of a hemisphere and very short, while the styles approach each other. The species are shrubs or herbs, natives of China and Japan; some are prickly, others unarmed; the leaves are alternate, once or twice pinnate, the leaflets serrate. Dr. Lindley, in his *Vegetable Kingdom*, states that '*D. edulis* is employed in China for exciting the action of the skin and producing perspiration; its young shoots are a delicate article of food, and its root, which is bitter, aromatic, and pleasant to the taste, is employed by the Japanese in winter, as we use *Scorzonera*.' [G. D.]

**DIMORPHOLEPIS.** An Australian genus of the composite family represented by one species, *D. australis*, an annual branching herb one to three inches high, with linear nearly smooth leaves, and stems clothed with loose tawny hairs, and terminated by small yellow flower-heads, which have an involucre of two sorts of scales, while the florets are all tubular, and the few outer female ones three-toothed. [A. A. B.]

**DIMORPHOTHECA.** A South African genus of herbaceous or half-shrubby Composite plants, embracing nineteen species. The heads are solitary and terminal, with yellow, brown, or rarely purple disk-florets, and rays either white above and purple

beneath, or purple and yellow. The best known species is *D. annua* (also called *D. pluvialis* from the closing of the flowers before rain), which is cultivated in gardens under the name of Cape Marigold. The name of the genus has reference to the two forms presented by the achenes. French, *Souci pluvial* or *hygromitre*. [J. Br.]

**DINEMANDRA.** A genus of heath-like Peruvian shrubs, belonging to the *Malpighiaceae*. They bear flowers in clusters, on small jointed stalks; the calyx in five divisions, each provided with one or more glands at its base; the stamens ten, united below, eight being sterile and short. The fruits consist of three-winged carpels. [M. T. M.]

**DINKEL.** (Fr.) *Triticum monococcum*.

**DINOPHORA.** A genus of the *Melastoma* family, nearly related to *Spennera*, from which it differs in its five, not three-celled ovary. It is represented by a single species, *D. spenneroides*, which is a smooth slender branching bush of three to five feet, found in moist places in Fernando Po, and bearing opposite stalked oval-acute leaves, the branches terminated by loose panicles of little pink flowers, which have a top-shaped calyx tube, five oval acute petals, and ten stamens. [A. A. B.]

**DIODIA.** A genus of *Cinchonaceae*, consisting of herbaceous plants or small shrubs, natives of Tropical America and Africa. They have small white flowers, with a calyx divided into two or four equal or unequal segments; a funnel-shaped corolla, the tube of which is lined with hairs, and the limb divided into four lanceolate divisions; four stamens inserted into the throat of the corolla; and an ovary adherent to the calyx tube, surmounted by a fleshy disk, and internally divided into two compartments, each containing a single ovule. [M. T. M.]

**DICECIA** (adj. **DICECIOUS**, **DIOICUS**). When the sexes of a plant are borne in different flowers by distinct individuals, as in willows. Expressed by the signs ♂ ♀.

**DIOICO-POLYGAMOUS.** When some of the flowers of a dioecious plant produce hermaphrodite flowers.

**DIOLENA.** A genus of *Melastomaceae* found in Venezuela, and nearly allied to *Sonerila*, but differing in having the parts of the flower in fives; and also to *Bertolonia*, from which it is recognised by the form of the anthers, which are ten in number, short obovate and open at top by two pores, while at the junction of the anther with its stalks there are two slender erect spur-like appendages. The only known species, *D. hygrophylla*, is a dwarf unbranched herb, with opposite long-stalked oval pointed entire leaves, and terminal one-sided raceme of small white flowers, succeeded by three-celled and three-winged capsules. [A. A. B.]

**DIONÉE ATTRAPE-MOUCHE.** (Fr.) *Dionaea muscipula*.

**DIONEÆ.** A singular plant referred to in most works on structural and physiological botany, as affording a striking instance of vegetable irritability. *D. muscipula*, Venus's Flytrap, the only species, belongs to the order *Droseraceæ*, and is an humble marsh plant bearing from the root, on a smooth leafless stalk a few inches high, a corymb of white flowers. The root is composed of scales almost like a bulb with a few fibres. From this proceed in a radiating manner a number of leaves on longish stalks, which are winged like those of the orange-tree. The lamina of the leaf itself is divided by the midrib into two nearly semicircular halves, each of which is fringed with stiff hairs, and furnished near the middle with three minute bristles arranged in a triangle, which bristles are extremely irritable, and when touched by a fly or other insect cause the two sides of the leaf to collapse with a sudden spring, imprisoning the intruder until it is either

*Dionaea muscipula.*

dead or ceases to move. Some time after all motion has ceased, they open again spontaneously. It is a native of the swamps of N. Carolina and Florida, but is often cultivated in English stoves. *Dionaea* is derived from Dione, one of the Greek names of Venus; *muscipula* is in Latin 'a fly-trap.' As might be expected, the same result is produced by touching the irritable bristles with any fine-pointed substance, as a pin or bit of straw. French, *L'attrape-mouches*; German, *Venus die fliegenfängerin*. [C. A. J.]

**DIONYSIA.** A genus of *Primulaceæ*, closely allied to *Gregoria*, and including all the Oriental species previously described under the latter name, but distinguished by Boissier from the European *G. italiana* on account of some slight differences in the seeds and in the shape of the corolla. They are all small Alpine tufted plants, with flowers intermediate between those of a *Primula* and of an *Androsace*.

**DION.** A family of Mexican *Cycadaceæ* with a simple *Samia*-like stem clothed with woolly hairs, and bearing light-green fanate leaves, whose leaflets are sword-shaped, very sharp, attached to the petiole

by their whole base. The female cone is about the size of a child's head, and consists of flat lance-shaped scales, covered with wool, and two-lobed at the base; each scale bears two large seeds of the size of chestnuts. The seeds of *D. edulis* yield a large quantity of starch which is used as arrowroot. [M. T. M.]

**DIORYCTANDRA.** This name, which has but slender claims to euphony, is applied to a shrub of the Violet family, in allusion to the passage of the style through the anthers. The genus is usually united with *Alcedia* from which it differs in the greenish petals, which are stalked, not sessile; and in the stamens which have slender filaments as long as the stalks of the petals. [M. T. M.]

**DIOSCOREACEÆ.** (Yams.) A natural order of monocotyledonous or Endogenous plants belonging to the subclass of *Dictyogeneræ*. Twining shrubs or herbs with tubers either above or below ground, usually alternate leaves with reticulated venation, and small staminate and pistillate flowers growing in spikes. Perianth six-cleft, in two rows, herbaceous and adherent; stamens six, inserted into the base of the perianth; ovary inferior, three-celled; ovules one or two, suspended; style three-cleft. Fruit compressed, three-celled, two cells often abortive; seeds albuminous; embryo in a cavity. They are found chiefly in tropical countries. *Tamus* is, however, a native of Europe and of the temperate parts of Asia.

Acridity prevails in the order, but it is often associated with a large amount of starch. Various *Dioscoreas* produce edible tubers, which are known as yams and are used like potatoes. *Tamus communis*, black bryony, has an acrid purgative and emetic tuber, and a berried fruit of a red colour. *Testudinaria Elephantopus* has a remarkably tuberculated stem, and has been called elephant's foot or the tortoise-plant of the Cape. The central part is eaten by the Hottentots. There are seven genera and 160 species. *Tamus*, *Testudinaria*, and *Dioscorea*, are examples. [J. H. B.]

**DIOSCOREA.** The typical genus of the order of yams. Upwards of 160 species are described, most of them being confined to tropical countries, principally in America and Asia, the majority, however, belonging to the former continent; about a dozen are found in Africa, and three or four in Australia. They are herbaceous perennials or undershrubs, with twining stems generally turning to the left hand; and fleshy tubercous roots; their leaves are usually produced alternately, but occasionally opposite, and, except in a few species where they are divided into several radiating lobes, they are always entire, and have several strongly-marked veins running throughout their entire length. The flowers, which are very small and inconspicuous, are produced in spikes from the bases of the leaves, and consist of a perianth of variable form, but usually

either bell or funnel-shaped; the males have six stamens, and the females a three-lobed ovary, surmounted by a style separating into three stigmas.

Under the name of Yams, the large fleshy tuberous roots of several species of this genus are extensively used for food in many tropical and subtropical countries, where they are largely cultivated, and take the place of our potatoes. Among the species most commonly employed for this purpose are: *D. sativa*, which is a native of Malabar, Java, and the Philippines; *D. alata* of the Moluccas and Java, and *D. aculeata* of Malabar, Cochín China, and Java, all of which are cultivated in various parts of tropical Asia, and likewise in the West Indies, where they have been introduced; besides which, *D. globosa*, *D. purpurea*, *D. rubella*, and *D. fasciculata* are cultivated in India, and other species elsewhere. Yams vary greatly in size and colour, according to the species or variety producing them; many attain a length of two or three feet, and weigh from 30 to 40 lbs.; some are white, others purplish throughout, while some have a purple skin with whitish flesh, and others are pink, or even black. Like potatoes they contain a large quantity of starch; and a nutritious meal, used for making cakes, puddings, &c., is prepared from them in the West Indies, where, also, they are commonly sliced and dried in the sun in order to preserve them.

One species, the Chinese or Japanese Yam, *D. Batatas*, has recently come into notice in this country, where it has been recommended for cultivation as a substitute for the potato; but although it succeeds very well when properly managed, it has not as yet found much favour among agriculturists. The chief drawback connected with it, is the great depth to which the roots penetrate into the earth, and the consequent difficulty of extracting them. It is extensively grown and used for food in China and Japan. [A. S.]

**DIOSMA.** A genus of heath-like plants, natives of the Cape of Good Hope, and belonging to *Rutaceæ*. It is nearly allied to *Barosma*, but differs in that the flowers have five fertile stamens, and no sterile ones, in the style being shorter than the stamens, in the more narrow leaves, and in other minor points. They possess a fragrance not unlike that of the kinds of *Bucku* (*Barosma*), and many of them are cultivated for their white or pinkish flowers, the most frequently met with being *D. capitata* and *ericoides*. [M. T. M.]

**DIOSPYROS.** Large hard-wooded trees, or rarely shrubs, belonging to the *Ebenaceæ*, which is so named in consequence of several species of this genus yielding the black wood called ebony. There are upwards of 100 species, the greater part of them natives of Asia and the Mauritius, only about a dozen being found on the American continent, and three or four in Africa; for the most part they are confined to the tropics, but a few extend as far north as

latitude 44°. They have flowers of separate sexes on different trees, and borne in little clusters, or singly at the bases of the leaves; the calyx divided into from four to six lobes; and the corolla tubular or bell-shaped. The fruit is fleshy or pulpy, generally either globose or egg-shaped, and varies greatly in size.

Ebony wood is obtained from several species of this genus. The best and most costly kind, with the blackest and finest grain, is that imported from the Mauritius, which is yielded by *D. reticulata*. East Indian ebony is mostly procured from two species, *D. Melanoxylon* and *D. Ebenaster*; while the best kind of Ceylon ebony is obtained from *D. Ebenum*. It is only the inner part of the trunk or heart-wood, as it is called, that yields the black ebony, the outer portion or sap-wood being white and soft. The chief uses of ebony are for fancy cabinet-making, mosaic work, and turnery, and for making a vast number of small articles, such as knife handles, door knobs and plates, pianoforte keys, &c.

*D. guajita* produces the beautiful wood called Calamander in Ceylon, and which the Chinese use for making the finest kinds of ornamental furniture. It is a very large tree, and the wood is so extremely hard that it is only worked with great difficulty. *D. Embryopteris* is a tree called Gaub by the Hindus. Its fruit is powerfully astringent, and is employed for tanning purposes. The juice of the unripe fruit is very viscid, and is used in India for paying the seams of boats; fishing nets are also coated with it to render them more durable.

The fruit of the Kaki or Chinese Date Plum, *D. Kaki*, is as large as an ordinary apple, of a bright red colour, and contains a yellow semi-transparent pulp resembling the flesh of a plum, both in appearance and flavour. The Chinese dry them in the sun, and make them into sweetmeats. The tree is a native of China and Japan, but is cultivated in India. *D. virginiana* is the Virginian Date Plum or Persimmon, a native of the United States, where it attains a height of fifty or sixty feet, with a trunk about a foot and a half in diameter, the heart-wood of which is of a brown colour, hard and elastic, but liable to split. The fruit of the Persimmon is an inch or more in diameter, nearly round, and of a yellowish orange colour, very austere and astringent even when quite ripe, but when blotted or softened by the action of frost it becomes eatable. In the Southern States, Persimmons are pounded and made into cakes with bran, and by adding yeast and hops to an infusion of the cakes a kind of beer is brewed; or, by fermenting and distilling them they yield a spirituous liquor. The bark of the tree is very bitter, and possesses febrifugal properties; it has been successfully employed by American physicians in cases of cholera infantum and diarrhoea. [A. S.]

**DIOTIS.** This name is usually applied to a genus of *Compositæ*, consisting of but one

species, *D. maritima*, or *candidissima*, a native of the shores of Europe from France southwards and eastwards, of the east and south coasts of England, and of N. Africa. It is an erect branched perennial herb, everywhere clothed with dense greyish wool. Its name 'two-eared' alludes to the ear-like corolla-lobes. The name has also been given to a Siberian Chenopodiaceous shrub, which is, however, generally and more properly united with *Eunomia*: which see. [J. Br.]

**DIPETALOUS.** Consisting of two petals.

**DIPHYLLEIA.** A genus of *Barberridaceae* containing a North American herb, with thick horizontal rhizomes, sending up a large roundish petate umbrella-like leaf deeply-lobed, or a flowering stem with two alternate excentrically petate deeply-cleft leaves with wedge-shaped segments, and a terminal cyme of rather small white flowers, having six sepals, six petals, and six stamens: fruit a blue few-seeded berry. The only species, *D. cymosa*, a native of Japan, and of the southern United States, is there called the *Umbrella Leaf*. [J. T. S.]

**DIPHYLLOUS.** Two-leaved.

**DIPHYSCIUM.** A curious genus of mosses allied to *Buxbaumia*, with large oblique nearly sessile capsules, an obscure or obsolete outer peristome, the inner being formed of a conical membrane with sixteen folds thickened at the prominent angles, as though so many thread-shaped outer teeth were united with it. There is but one well-established species which occurs on shady banks and barren places in mountainous districts. The leaves are narrow and linear, and resemble somewhat those of *Polytrichum*. The plant looks like a monstrous *Phascum*. [M. J. B.]

**DIPLACUS.** A genus of *Scrophulariaceae*, closely allied to *Mimulus*, from which it chiefly differs in a shrubby habit, and in the capsule which, on opening, carries away the seed-bearing placenta attached to the valves. There are three or four species known, all natives of Mexico or California. *D. glutinosus*, a native of Northern California, has long been cultivated in our gardens under the names of *Mimulus glutinosus*, *M. aurantiacus*, or *D. punctatus*. It is an erect branching plant, becoming more or less shrubby at the base, the young branches being often very viscid. The leaves are opposite, varying from broadly-oblong to narrow-lanceolate. The flowers are rather large, solitary in the upper axils, and vary from a pale yellow to a rich orange or scarlet.

**DIPLADENIA.** The generic name of plants belonging to the order of dogbanes, distinguished principally by the presence of two blunt glands at the base of the seed-vessel, each of which is apparently formed of two conjoined. The name *Dipladenia*, "double gland," appropriately indicates the chief character. The species are climb-

ing shrubs or undershrubs, natives of Central America, having opposite entire leaves, and at their point of attachment often provided with glands or bristles; the flowers are handsome, springing from near the point of insertion of the leaves, or in terminal clusters. These plants are near allies of the well-known genus *Echites*, in which indeed some of them were formerly included.

The species of *Dipladenia* are divided into two sections: 1. Those in which the glands at the base of the seed-vessel are large and well developed, and the appendages at the insertion of the leaves, small or wanting; 2. Those having the glands small. There are some differences in the general outline of the corolla. In certain species it is almost salver-shaped, the tube slightly inflated at the top; in others the tubular part is cylindrical below, and funnel-shaped above. Some approach the herbaceous character, with narrow leaves; others are undershrubs with broader leaves. Several species must be ranked with the finest of our stove plants, and are among the more important and recent acquisitions of collectors.

The twining habit, the large and graceful flowers and general appearance of the foliage are sufficient recommendations. *D. crassinoda*, *nobilis*, *splendens*, and others, occupy a prominent place as stove climbers. The charming and finely-coloured convolvulus-like flowers of *D. splendens* succeed each other for weeks. [G. D.]

**DIPLANDRA.** A genus of onagrads, distinguished by having the calyx in four lanceolate divisions, two of which are often joined; the corolla has four divisions, one larger than the others, all attached to the calyx and shorter than it. The name *Diplandra* indicates another character, viz. the presence of two stamens only, opposite to two pieces of the calyx. The only species, *D. lopezoides*, a native of Mexico, is a branched hairy shrub, with opposite shortly-stalked leaves, which are oblong and narrow toward the end, almost entire, and hairy on both surfaces. The flowers are purple, forming clusters. [G. D.]

**DIPLANTHERA.** A scrophulariaceous tree, native of tropical Australia, with large four-lobed stalked leaves, which have two glands at their base, and terminal clusters of handsome flowers, with yellow two-tipped corolla, and four projecting stamens. [M. T. M.]

**DIPLARCHE.** A genus of *Ericaceae*, consisting of evergreen, heath-like undershrubs, with prostrate stems, and small rose-coloured flowers arranged in terminal heads. It is botanically characterized by the presence of ten stamens in two rows, the upper placed upon the corolla (perigynous), the lower arising from beneath the ovary (hypogynous), a most unusual circumstance. These shrubs are natives of the Himalayan mountains. [M. T. M.]

**DIPLASPIA.** A genus of *Umbelliferae*, consisting of two species, natives of the

South Eastern Alps of Australia and of Tasmania. They are small herbs with radical stalked cordate or reniform leaves, and simple scapes bearing a small simple umbel of flowers. They have thus the habit of *Hydrocotyle*, whilst the fruit is nearly that of a *Bolax*.

**DIPLEX.** A genus of grasses belonging to the tribe *Oryzæ*, distinguished by the inflorescence being in panicles, the spikelets two-flowered; glumes two, unequal, the inferior one nerved, blunt and ovate, the superior much larger; lower floret sterile; stamens two or one; styles short and smooth. *D. avenacea*, the only species, is a native of New Zealand. [D. M.]

**DIPLAZIUM.** A genus of polypodiaceous ferns, belonging to that group of the *Aspleniceæ* which have the indusia connate in pairs set back to back on the same vein, the veins in this case being free. The limit between *Diplazium* and *Asplenium* is not very definite, certain of the species bearing but few of the double sori of *Diplazium* amongst many of the single sori characteristic of *Asplenium*. On this account the two groups have been reunited by some modern botanists. It is, however, more convenient to keep them distinct. The species are rather numerous and very varied in size, form, and habit, some bearing simple fronds like *Scolopendrium*, others very large bipinnate or tripinnate fronds. There is a tendency in many of them to develop a short stem. [T. M.]

**DIPLECOLOBEÆ.** A subdivision of cruciferous plants, embracing those in which the cotyledons are twice folded, and the embryo, when cut across, presents this appearance, O || || ||, in which O represents the cut radicle, which is placed on the back of the two cotyledons marked by lines || to show that they are cut across three times. Among the genera in this section of *Cruciferae* are placed *Senebiera*, *Brachycarpea*, *Subularia*, *Heliophila*, *Schizopetalum*, and a few others. [J. H. B.]

**DIPLESTHES.** A name sometimes given to the Cape species of *Salacia*.

**DIPLOCALYMNA.** An imperfectly described genus, included by its author, Sprengel, among *Pentandria*, and subsequently referred to *Thunbergia* (*Acanthaceæ*), but incorrectly if Sprengel's description can be trusted; and also to *Convolvulaceæ*, with no genus of which, however, does it seem to be allied. The genus is founded on a twining plant, without a locality, having the appearance of a *Convolvulus*. It is described as possessing a double calyx, the outer two-valved and the inner ten-toothed; the corolla infundibuliform, and subuplicate; the anthers sagittate and included; the stigma urceolate and sublobed. [W. C.]

**DIPLOCENTRUM.** A genus of epiphytal orchids found growing on tree stems in the Madras presidency. The three known species, *D. rostratum*, *lanifolium*, and *compressum*, are furnished with strap-like chan-

neled leaves notched at the apex, and axillary racemes, or panicles of small pink flowers with a crimson lip, or the petals are dull brown with a lilac lip. The lip has two instead of one short spur, whence the name, and this is the only character which separates the genus from the well-known *Vanda*. [A. A. B.]

**DIPLOCLINIUM.** A genus of begonias, separated from *Begonia* by Lindley, but subsequently restricted by Klotzsch. It contains plants which are found in the East Indies and in Java. The staminate flowers have four, the pistillate three sepals; anthers oblong with narrow lateral filaments; filaments slightly united at the base; style persistent with two lunate branches furnished with a continuous papillose band; placentas split lengthwise. There are five species. The name refers to the divided placenta. [J. H. B.]

**DIPLOCLISIA.** This genus of *Menispermaceæ*, proposed by Miers, has been referred by Drs. Hooker and Thomson to the genus *Cocculus*, from which it differs only in the elongated drupe, a character not of sufficient importance in the judgment of those authors to constitute a new genus. [M. T. M.]

**DIPLOE.** That part of the parenchyme of a leaf which intervenes between the two layers of epiderm.

**DIPLOGENEA.** A genus of *Melastomaceæ*, nearly related to *Medinilla*. The only known species, *D. viscoidea*, is found in Madagascar, where it grows on trees, and has somewhat the appearance of mistletoe, but is not like that, a parasite. It has fleshy smooth three-nerved leaves, between oval and elliptical in form, and small flowers arranged in axillary cymes. These have a bell-shaped calyx, with a nearly entire fleshy border, four oval petals, and eight equal stamens. Its leaves are said to be furnished with dots like those seen in myrtles. [A. A. B.]

**DIPLOLÆNA.** A genus of shrubs natives of New Holland, belonging to *Rutaceæ*. They have alternate stalked dotted leaves with stellate hairs on the upper surface, and thick white down on the lower. The flowers are borne within a many-parted involucre, the bracts of which are arranged in three rows, the outermost being woolly, the inner petaloid. [M. T. M.]

**DIPLOLOMA.** A genus of *Borraginaceæ* allied to *Cynoglossum* and more nearly to *Solenanthus*. It has a tubular corolla with five bosses at the throat and an erect five-cleft limb; stamens longer than the corolla; nuts adhering to a central column by their inner angle, crowned and margined by a ring. A native of the Altai. [J. T. &]

**DIPLOMORPHA.** A name at one time given to a few plants of the daphnoid family which are now generally known as species of *Wikstrœmia*. [A. A. B.]

**DIPLOPAPPUS.** A genus of perennial bushes or dwarf herbs of the composite

family, very near *Aster*, and only differing in the nature of the pappus, which is double, the outer row of short stiff bristles, the inner of capillary bristles as long as the disk florets; whilst in *Aster* the pappus is single. About twenty species are known, some found in South Africa, others in China and the Himalayas, and the remainder chiefly in North America. The most of the Cape species are smooth bushes with small linear or oblong leaves, and solitary stalked flower-heads terminating the twigs. *D. asper*, of the same country, is an herb about a foot high, with sessile lance-shaped leaves, entire or toothed at the margin, and handsome flower-heads, which are solitary and supported on long naked stalks, and nearly two inches across, the ray florets being strap-shaped and purple, those of the disk tubular and yellow. A goodly number of those found in the Himalayas are handsome Alpine plants, with short unbranched stems, furnished with oblong toothed or entire leaves, and terminated by single flower-heads one to two inches in diameter, the outer florets strap-shaped and violet, the inner yellow and tubular. The North American species are mostly shrubby, with linear or lanceolate leaves, and terminal corymbs of flower-heads of which the ray florets are either blue, purple, or white. Almost the only species found in South America is *D. lavandulifolia*, a large handsome bush found on the Peruvian Andes at an elevation of 11,000 to 12,000 feet; its closely packed leaves are covered underneath with white down, and the numerous little twigs are each terminated by a purple-rayed flower-head. This plant and a few of the North American species are also known under the generic name of *Diplostephium*, and some of the former are known also by the name *Eucephalus*. [A. A. B.]

**DIPLOPELTIS.** A genus of *Sapindaceæ* composed of three W. and N. Australian shrubs from one to three feet high, with alternate wedge-shaped and toothed, or sometimes pinnatifid leaves, and terminal panicles of white, pink, or violet flowers, each about half an inch across. All the parts of the plant are usually covered with a short white glandular pubescence. The flowers are male and female on the same plant, the former with a calyx of five leaves, five oblong petals, and usually eight stamens; the latter with a similar calyx and corolla, and a three-lobed ovary crowned with a simple twisted style. The somewhat herbaceous appearance of the plants is almost enough to distinguish them in the family, which is for the most part composed of bushes or trees, with pinnate or trifoliate evergreen leaves. [A. A. B.]

**DIPLOPHYLLUM.** A name at one time given to *Veronica arvensis galii*; a species much like *V. Eusebaumi*, which is naturalized in Britain. [A. A. B.]

**DIPLOPOGON.** A genus of grasses belonging to the tribe *Pappophoræ*, distinguished by the inflorescence being in close

head-like spikes; spikelets one-flowered; glumes two, lax, membranaceous, and awned; stamens three; ovary sessile; styles two, joined at the base; stigmas feathery. *D. setaceus*, the only species, is a native of New Holland. [D. M.]

**DIPLOPTERYS.** A genus of *Malpighiaceæ*, consisting of a climbing shrub native of Guiana, with yellow flowers disposed in an umbellate manner, and surrounded by a series of bracts. The calyx has five segments, four of which are provided with two glands; stamens ten, slightly coherent at the base; ovary three-lobed, three-celled; styles three; fruit with five somewhat woody wings. [M. T. M.]

**DIPLOSIPHON.** A genus of *Hydrocharidaceæ*, an annual herb growing in rice fields in India, with radicle leaves arranged in a rosette; and axillary perfect flowers from a spathe split at the apex. The perianth tube is twice as long as the spathe, the three outer segments of the limb herbaceous, the three inner larger, petaloid, white; stamens three; style long, adhering to the perianth tube; fruit membranous, many-seeded. [J. T. S.]

**DIPLOSPORA.** A Chinese shrub of the cinchona family, but imperfectly known. The calyx tube is obovate, its limb somewhat bell-shaped, four-toothed: the corolla with a wide tube, hairy at the throat, and with a limb divided into four fleshy spreading segments; the anthers four, sessile, projecting. *D. dubia* or *Canthium dubium* is a shrub with axillary tufts of white flowers. [M. T. M.]

**DIPLOSTEMONOUS.** Having twice as many stamens as petals.

**DIPLOSTEPHIUM.** *Diplopappus*.

**DIPLOTAXIS.** A family of unimportant herbaceous plants, belonging to the *Cruciferae* and allied to *Sinapis*, distinguished by having the seeds arranged in two rows in a long compressed pod. *D. tenuifolia* is a slender glabrous perennial plant with a branched stem shrubby at the base, bluntly divided leaves, and rather large light-yellow flowers. It grows in quarries, on rubbish and walls, near large towns. *D. muralis* is a smaller species, an annual whose stems and leaves are rough with scattered hairs. [C. A. J.]

**DIPLOTEGIA.** An inferior capsule.

**DIPLODODON.** A genus of *Lythraceæ*, consisting of Brazilian herbs and shrubs with opposite often four-angled branches, opposite or verticillate entire leaves, and solitary axillary nearly sessile flowers, arranged in a racemose or even capitate manner. They have a bell-shaped twelve-toothed calyx, with the teeth arranged in two rows: six petals, and from twelve to forty stamens. [J. T. S.]

**DIPODIUM.** A genus of terrestrial leafless orchids of Australia and New Caledonia, belonging to the tribe *Vandææ*. They have thick branching roots, and

stems one to two feet high furnished at intervals with brown scales, and terminating in large racemes of numerous rose-coloured nearly regular flowers about an inch across. The oblong clawed lip is two-eared at the base and slightly bearded at the apex. There are two pollen masses each with a separate caudicle, whence the generic name signifying two feet. There are three known species. A beautiful figure of *D. punctatum* will be found among the illustrations to Dr. Hooker's *Flora of Tasmania*. [A. A. B.]

**DIPSACACEÆ (Teazelworts.)** A natural order of gamopetalous calycifloral dicotyledons or Exogens, belonging to Lindley's campanal alliance, embracing herbs or undershrubs with opposite or whorled ex-stipulate leaves, and flowers in heads surrounded by an involucre; calyx adherent, membranous, surrounded by a separate covering or involucrel; corolla tubular, with an oblique four to five-lobed limb; stamens four; anthers distinct; ovary one-celled; ovule pendulous. Fruit dry, not opening, crowned by the pappus-like calyx; seed albuminous. Natives chiefly of the south of Europe, Barbary, the Levant and the Cape of Good Hope. Astringent qualities reside in some of the species. Some are used in dressing cloth. *Dipsacus Fullonum* is the fuller's teazel, the dried heads of which, with their hooked spiny bracts, are used in fulling cloth. The opposite leaves of the wild teazel, *D. sylvestris*, unite at their bases so as to form a cavity in which water collects; hence the plant was called *Dipsacus* or thirsty. There are six known genera and about 170 species. *Morina*, *Dipsacus*, *Cephalaria*, and *Scabiosa* afford examples. [J. H. B.]

**DIPSACUS.** The Teazel family, typical of the order *Dipsacaceæ*. It forms a small genus of prickly biennial plants, natives of Europe and Northern Asia, having oblong or globular heads of flowers, surrounded by an involucre of several narrow bracts, the individual flowers separated by long prickly scales, and inserted into a small angular outer calyx (involucrel). The true calyx has a small cup-shaped border surmounting the involucrel, and the corolla is divided into four unequal lobes.

*D. sylvestris*, the common Teazel, is a native of the southern parts of England and Ireland, also of central and south Europe, and Russian Asia. It grows from four to six feet high, and is very prickly in all parts; the leaves long, lance-shaped, and stalked, those on the upper part of the stem growing together by their bases, and forming a cup, which is generally found full of clear water. The heads of flowers are cylindrical, and between two and three inches long, by one and a half broad, having an involucre of from eight to twelve stiff prickly bracts curved upwards, and the scales separating the flowers terminate in a long straight sharp point.

*D. Fullonum*, the Fuller's Teazel, is by most botanists supposed to be merely a

variety of the preceding, from which it only differs in the scales of the flower-heads being hooked instead of straight, and the involucrel bracts being shorter and spreading. The flower-heads of this plant, under the name of Teazels, form an article of considerable importance to the cloth manufacturer, who employs them for raising the nap on cloth, no machine having yet been invented to supplant them. For this purpose they are fixed in regular order upon cylinders, which are made to revolve in such a manner that the hooks of the Teazels come in contact with the surface of the cloth, and thus raise a nap, which is afterwards cut level. The plant is cultivated in some parts of this country, also in France, Austria, and other parts of Europe. In 1855 the enormous number of 18,907,120 teazel-heads were imported, all of which came from France, and were valued at five shillings per thousand. [A. S.]

**DIPTERACANTHUS.** A large genus of *Acanthaceæ*, containing nearly 100 described species, chiefly from Central and South America and Asia, with a few from Africa and Australia. They are creeping or erect herbs or rarely shrubs, with solitary or fasciculate flowers, collected at the ends of the stem and branches into racemes. The lower flowers have large leafy bracts, which become small and narrow in the crowded racemes; the calyx is more or less deeply five-cleft, and the corolla is funnel-shaped with a five-cleft limb; the four didynamous stamens are included, and the stigma is bilamellate. [W. G.]

**DIPTERACEÆ (Dipterocarpeæ, Dipterocads.)** A natural order of thalamifloral dicotyledons or Exogens, belonging to Lindley's guttiferal alliance, containing large trees with resinous juice; alternate involute leaves with convolute stipules; long unequal calyx lobes; twisted petals, and stamens above twenty, distinct or united in several bundles. Fruit leathery, one-celled, surrounded by the calyx, the enlarged divisions of which form winged appendages; seeds single, without albumen. Tropical Indian trees found especially in the islands of the Indian Archipelago. They yield a resinous balsamic juice. *Dipterocarpus laevis* or *turbinatus*, the gurgun of Chittagong, yields wood-oil which exudes from the trunk, and is used as pitch, varnish, and medicine. *Dryobalanops Camphora* or *aromatica*, a tree from 100 to 130 feet high, supplies the hard camphor of Sumatra, which exists in a solid state in the interior of the stem, sometimes in pieces weighing from 10 to 12 lbs. It also yields by incision a resinous oily fluid called the liquid camphor or camphor-oil of Borneo. Sometimes five gallons of the liquid are found in a cavity in the trunk. The wood of *Vateria* or *Shorea robusta* is used in India under the name of sal. Dhooa pitch is also procured from the plant. *Vateria indica* yields the piney resin or piney dammer of India, which is used as a varnish, and for lighting. There

are seven known genera and forty-seven species, including *Dipterocarpus*, *Dryobalanops*, *Vateria*, and *Shorea*. [J. H. B.]

**DIPTERIS.** A beautiful genus of polypodiaceous ferns, sometimes referred to *Polypodium* itself, but differing in the netted venation, and in the bilate digitato-palmately-lobed or repeatedly dichotomously-partite fan-like fronds. Two or three species only are known, and these are beautiful plants of India and the Archipelago, with tall slender rod-like stipes, and fan-shaped palm-like coriaceous fronds, which rise from a freely creeping woody rhizome. The sori are small, round, and very numerous in *D. conjugata* and *D. Wallichii*, in which the costa is dichotomously-branched in the ultimate segments of the frond; but uniserial in *D. Lobbiana*, in which there is a simple central costa in each of the narrow and more completely separated ultimate divisions. The reticulation of the veins is highly compound. [T. M.]

**DIPTERIX.** One of the few genera of leguminous plants bearing a single-seeded fruit, which does not open naturally at maturity; the pod which bears this is called drupaceous. There are eight species belonging to the genus, all of them large trees inhabiting the forests of Brazil, Guiana, and the Mosquito country, and having pinnate leaves and panicles of flowers. The flower is characterised by having a two-lipped calyx, the upper lip consisting of two large lobes spreading like wings, while the lower is very small and either of three teeth or only one; the stamens are eight or ten in number and united together into a sheath, which is split on the upper side.

*D. odorata* yields the fragrant seed called Tonquin, Tonka, or Tonga bean, used for scenting snuff. Perfumers also obtain an extract from it, which forms an ingredient in some bouquets, and the pulverised seed is employed in the preparation of sachet powders. The odour resembles that of new-mown hay, and is due to the presence of *coumarine*. The tree producing these seeds grows sixty or eighty feet high, and is a native of Oryenne. The fruit bears some resemblance to that of the almond tree, and the seed or bean is shaped like an almond, but much longer, and is covered with a shining black skin.

*D. ebenata*, the Eboe tree of the Mosquito shore, has a fruit and seed greatly resembling the preceding in appearance, but entirely destitute of the odoriferous principle. It, however, contains a large quantity of fatty oil, which the natives of the Mosquito country extract and use for anointing their hair, for which purpose it is said to be peculiarly suitable. It is a large tree, and produces an excessively heavy yellowish-tinted timber. [A. S.]

**DIPTEROCARPUS.** A name indicative of the two calycine wings, which surmount the fruit of these plants, which give their name to the order of *Dipteraceae* or *Dipterocarpeae*. The genus consists of

lofty trees, abounding in resinous juice, with leathery leaves, covered in some instances with star-shaped hairs. The flowers are in clusters, large, white or pink, fragrant; the calyx divided into five unequal segments, two of them becoming very large and leaf-like; petals five; stamens numerous, with linear anthers; ovary with two ovules in each of its three compartments, included within the tube of the calyx. Fruit woody, one-celled, one-seeded by abortion, surmounted by the persistent and enlarged calyx. These trees are natives of the Indian islands, where the resin is made use of medicinally, and for burning in torches. *D. laviia* yields in Eastern India and the Malay Islands a thin liquid balsam called wood-oil, which is employed for painting ships and houses. The resinous fluid is collected by cutting

*Dipterocarpus trinervis.*

a deep notch in the trunk of the tree near the ground, where a fire is kept until the wood is charred, when the liquid begins to ooze out. This wood-oil is now imported into this country as a substitute for balsam of Copaliba, which it greatly resembles. By the application of heat it becomes concentrated and semi-solid. The resin mixed with dammer is valuable in preserving timber from the ravages of white ants, according to Dr. Wight. [M. T. M.]

**DIPTEROUS.** Having two wing-like processes.

**DIPTERYGium.** A herbaceous plant, native of Arabia, Nubia, and N.-W. India, with thickish leaves, and flowers in terminal clusters provided with bracts. The calyx and corolla four-parted; stamens six, four somewhat longer than the other two; ovary four-cornered, one-celled, with a cylindrical style and capitate stigma; pod indehiscent, compressed, provided with a membranous wing, one-celled, one-seeded. This plant seems to have nearly equal claims to be comprised among *Oncofera* and *Capparidaceae*. [M. T. M.]

**DIPYRENA.** A genus of *Verbenaceae*, found in Ouhil, and represented by *D. glabrescens*, an erect rigid bush, with narrow oblong somewhat fleshy entire

leaves, alternate on the stems, and often arranged in bundles of four or five. The twigs terminated by a loose spike of tubular sweet-scented flowers resembling those of the *Verbenas* so commonly seen in our flower-beds. Indeed the plant would be a *Verbena* were it not that the fruit is composed of two little nuts or pyrenes (whence the name) instead of four. A still closer relationship exists between this plant and *Priva*; the latter, however, has an herbaceous stem. [A. A. B.]

**DIPYRENOUS.** Containing two stones or pyrenae.

**DIRCA.** A genus of *Thymelaeaceae*, with hermaphrodite flowers, the perianth coloured, somewhat bell-shaped and oblique; the stamens eight, inserted in two rows in the tube of the perianth; the ovary one-celled, with a single pendulous ovule. The fruit is drupaceous. There is one species, *D. palustris*, a North American shrub called Leather-wood, Moose-wood, and Wicopy; the twigs are used as thongs; fruit poisonous; leaves alternate entire; flowers pale yellow. [J. H. B.]

**DIRCÆA.** A genus of *Gesneriaceae*, consisting of Brazilian herbs with tuberous rhizomes, and herbaceous stems bearing large opposite leaves, and long-tubed showy panicle flowers, often of a rich scarlet colour. The group is typified by the species formerly known as *Gesnera faucialis*, *bulbosa*, &c., and is distinguished by the great development of the upper lip of the corolla. [T. M.]

**DIS.** An Algerian name for the fibrous stems of *Festuca patula* and *Arundo tenax*, which are used for cordage.

**DISA.** A numerous genus of terrestrial orchids peculiar to South Africa and

*Disa grandiflora.*

Abyssinia. The species vary much in habit, but most agree in having the sepals

usually much larger than the petals, and the posterior sepal instead of the labellum, as in *Habenaria* and other allied genera, is furnished with a more or less evident hood-like spur. *D. grandiflora* is perhaps the most beautiful of all terrestrial orchids, and is spoken of by Dr. Harvey as the pride of Table Mountain, where it grows in great profusion on the borders of streams and water pools which are dry in summer, producing its gorgeous flowers in February and March. The stems grow two and a half feet high, and are furnished with a number of broad grassy leaves, and terminated by from one to four splendid flowers, measuring from three to five inches across. The lateral sepals are of a bright crimson, the dorsal one paler on the outside, and bluish-coloured and delicately veined with crimson within. Unfortunately this plant is very difficult to cultivate, and is therefore not so frequently seen in our gardens as it deserves to be. It is beautifully represented in *Lindley's Sertum Orchidaceum*, t. 48. *D. spatulata* is a most remarkable species from the long and slender stalk of the lip, which much exceeds the flower in length, and has a trowel-shaped more or less lacerated apex. Many species have rose-coloured flowers, but in a goodly number there is a charming mixture of blue, white, green, and purple, in the same flower. [A. A. B.]

**DISANDRA.** A trailing plant often seen in greenhouses, referred by some botanists to *Sibthorpia*.

**DISCANTHUS.** A palm-like plant from the Andes of Eastern Peru, forming a genus of *Cyclanthaceae*. It has the long radical trifid leaves, and the inflorescence of a *Carludovicia* or of a *Cyclanthus*, and most of the characters of the latter genus; but it differs chiefly in the perianth consisting of distinct disks embracing the spadix, and in the ovules being naked from their first appearance. The lobes of the leaves have also only one strong rib, and are not plicate as in *Cyclanthus*.

**DISCARIA.** A genus of *Rhamnaceae*, nearly allied to *Colletia*, but differing in having no petals. One species, *D. australis*, is common to Tasmania, New Zealand, and Australia, and the others are found in extra-tropical South America. All of the twelve known species are spiny undershrubs of no beauty, some almost leafless, and others with minute oblong or spatulate smooth leaves. The small opposite secondary branches terminate in a sharp spine, and towards their base are found, in twos or threes, the little flowers, which have a short bell-shaped calyx tube, and from four to five small scale-like hooded petals. [A. A. B.]

**DISCHISMA.** A genus of *Selaginaceae*, containing nine species from Southern Africa. They are herbs or herbaceous shrubs, with linear entire or dentate leaves, and flowers in more or less hairy terminal bracteate spikes, the corolla tube

short, and the limb fissured in front, and consisting of a single four-lobed lip; there are four sub-seaile stamens with one-celled anthers. [W. C.]

**DISCIFORM.** Flat and circular; the same as Orbicular. Also a name given to the chambered pith of such plants as the walnut.

**DISCIPLINE DE RELIGIEUSE.** (Fr.) *Amaranthus caudatus*.

**DISOCACTUS.** A genus of *Cactaceæ*, consisting of two or three species, natives of the West Indies and Brazil, remarkable for having very short flat fleshy stems, which are only about two inches in height, and from four to six broad, with eight or ten ridges bearing at intervals little bundles of stiff prickles. The flowers are produced from out of a mass of silky wool and slender spines with which the plant is crowned; they have a long narrow tube, the sepals spreading and coloured, the petals white and spreading out very flat, the stamens of different lengths closing up the tube of the flower, and the style thread-like, shorter than the stamens, and divided at the top into five radiating stigmas. The flowers of *D. insignis* have a very pleasant odour, somewhat resembling that of orange flowers; while that of *D. alticola* is not so pleasant. [A. S.]

**DISOCAPNOS.** A genus of *Fumariaceæ*, distinguished by having the fruit membranous, orbicular, flattened, and winged all round. The flowers are nearly as in *Corydalis*, but with the inner petals united. It is a Cape annual with bipinnate leaves glaucous beneath, and climbing by the petioles. [J. T. S.]

**DISOCARPUM.** A collection of fruits placed within a hollowed receptacle, as in many roseworts.

**DISOCARPUS.** *Disocarpus*.

**DISCOIDAL.** Orbicular, with perceptible thickness, slightly convex, and a rounded border.

**DISCOLOR.** Parts having one surface of one colour, and the other of another colour. Also any green colour altered by a mixture of purple.

**DISCOPHORA.** A genus of *Isacnaceæ*, containing a shrub from Guiana, with large smooth leathery shortly-stalked leaves, and axillary racemes of small flowers articulated with the flower-stalks. [J. T. S.]

**DISCOPIDIUM.** The foot or stalk on which some kinds of disks are elevated.

**DISCOSTEGIA.** A name proposed for a few marattiaceous ferns including *Marattia alata*. [T. M.]

**DISCOSTIGMA.** *Garcinia*.

**DISEASES OF PLANTS.** Plants like animals are subject to diseases both functional and organic. They arise from various causes, being often strictly constitutional and hereditary; and frequently, on

the other hand, induced by bad food, imperfect nutriment, depraved atmosphere, defect of light, &c. A very important class again arises from the attacks of parasitic animals and *Fungi*, while others are the direct consequences of injury from external agents. Many of the objects of cultivation, in which some particular organ or element of the plant is preternaturally developed, are really in a diseased state, the peculiar condition being induced artificially, or, at least, encouraged to supply the wants of man, exactly as the livers of geese are compelled to put on a diseased action to afford materials for the pâté. The blanched stems and leafstalks of celery, the swollen stems of kohlrabi, the enlarged roots of turnips and carrots, &c., are all so many instances of diseased action compelled to administer to our necessities.

The study of vegetable diseases is essential to good cultivation, for though little can be done towards arresting disease in any individual plant, much may be done, either rationally or empirically, in preventing the spread of those which are infectious or contagious, and more by guarding against those conditions which induce disease. The principal maladies to which plants are subject will be noticed briefly under their respective heads. [M. J. B.]

**DISEMMA.** A genus of *Passifloraceæ*, closely allied to *Passiflora*, but distinguished from it by the corone, which consists of an outer row of thread-like processes, and an inner tube with longitudinal plaits. They are shrubs, natives of tropical Australia, and have entirely the appearance of passionflowers. [M. T. M.]

**DISEPALUM.** A Borneo tree forming a genus of *Anonaceæ*, remarkable for the sepals and the petals of each series being two only, instead of three, as in the rest of the order.

**DISETTE.** (Fr.) A kind of Beet.

**DISK.** An organ intervening between the stamens and ovary; it assumes many forms, the most common of which is a ring or scales; it is apparently composed of metamorphosed stamens. Also the receptacle of certain fungi, or the hymenium of others.

**DISOCACTUS.** A small Cactaceous genus, scarcely separable from *Phyllocactus*. The only species, *D. biformis*, is a native of Honduras, and forms a weak trailing shrub or bush, with stem and older branches nearly cylindrical, gradually tapering upwards, and woody; while the younger branches are broad and flat, with blunt teeth, resembling leaves in appearance, but of a succulent or fleshy nature. Like most plants of the order, it has no real leaves. The flowers are produced singly from one of the notches at the upper end of the young branches, and are characterised by having only four sepals and four petals, both of a deep pink colour, and about two inches in length, the sepals very narrow and bent

backwards, and the petals broader and growing so close together for the greater part of their length as to form a tube. The fruit is of a beautiful shining deep crimson colour, shaped like a little Florence-flask; it contains numerous seeds, imbedded in a soft pinkish pulp, which has a sweetish sub-acid taste. [A. S.]

**DISOCARPUS**, more correctly **DISOCARPUS**. A small genus of South American trees, belonging to the *Euphorbiaceae*, with smooth oval entire leaves two or three inches long, a good deal like those of the Portugal laurel, and axillary bundles of small sessile flowers of which the male and female are on different plants. The males have a cup-shaped calyx of five unequal divisions, no petals, and five stamens; while the females have five petals, five rudimentary stamens, and a three-lobed ovary. Three species are known. The genus differs from its near allies in the absence of petals in the male flowers, and the presence of rudimentary stamens in the females. [A. A. B.]

**DISOON**. A genus of *Myoporaceae*, represented by *D. floribundum*, a smooth slender graceful bush, six feet high, found in South-eastern Australia. It has alternate linear leaves, and a great profusion of little bell-shaped flowers arranged in axillary clusters, and having a five-toothed calyx which does not grow larger after the flower withers, a five-toothed border to the corolla, and four protruding stamens. The fruit is a little two-celled drupe with two seeds. The nature of the fruit, and the calyx not enlarging after the fading of the flower, are the most marked characters. [A. A. B.]

**DISPHENIA**. A small set of cyatheaceous ferns, now generally included in *Cyathea* itself, but separated by some authors on account of the elevated receptacle being split into two wedge-shaped divisions. [T. M.]

**DISPORUM**. A genus of *Melanthaceae*, belonging to the group connecting that order with *Liliaceae*, of which *Uvularia* is the type. The species which occur in India are herbs with subsessile leaves and few-flowered axillary peduncles, the perianth six-cleft, with each division keeled and bulging at the base, the whole forming an angular tube. [J. T. S.]

**DISSECTED**. Cut into many deep lobes.

**DISSEPIMENTS**. The partitions in a fruit caused by the adhesion of the sides of carpellary leaves. — **SPURIOUS**. Any partitions in fruit which have not the origin just explained.

**DISSOMERIA**. A genus of *Homaliaceae*, represented by a shrub native of Western tropical Africa, the parts of whose flowers are arranged in fours, the eight petals alternate with as many glands; the stamens numerous, in eight bundles opposite to the petals, the anther-lobes separated by a thick fleshy connective: ovary one-

celled; styles four or three. Fruit indehiscent, seeds few by abortion. [M. T. M.]

**DISSOTHRIX**. A genus of the composite family found in Brazil. *D. Gardneri*, the only species, is a slender annual herb, a foot and a half high, with erect stems terminating in a loose panicle of small flower-heads, and furnished with stalked nearly oval leaves toothed at the margin, opposite on the lower part of the stem and alternate above. Each flower-head has from five to eight tubular five-toothed florets, enclosed in an involucre formed of two series of lance-shaped scales. The achenes are five-angled, and crowned with a pappus of numerous hairs of two sorts, the greater proportion capillary, but five longer than the rest, more rigid, and corresponding to the angles of the achenes. The nature of the pappus serves to distinguish the genus from *Stevia*, to which it is most nearly allied. [A. A. B.]

**DISSOTIS**. A genus of Tropical African melastomaceous plants, nearly allied to *Oubekia*, from which it differs in having dissimilar stamens. Twenty species are described, herbs or shrubs, from one to three feet high, with opposite lance shaped three to five-nerved leaves, which as well as the four-sided stems, are clothed with soft-spreading hairs. The rosy or purple flowers generally in threes at the ends of the twigs, and about an inch across, have the tube of the calyx beset with hairy tubercles, and its border five-toothed; five rounded petals; and ten stamens, the latter of two sorts, the five opposite the petals having their anthers joined to the filament by a long slender connective, while those opposite the calyx teeth have a very short or almost obsolete connective. *D. Irvingiana*, a pretty species found in Abbeokuta, is now cultivated in England. [A. A. B.]

**DISTEGANTHUS**. The name of a parasitical bromeliaceous plant, with yellow flowers, which have a six-parted perianth, the three inner divisions of which form a kind of spiral tube below, while above they are petal-like and somewhat concave; stamens six, thick, hidden by the scales of the inner divisions of the perianth; style twisted at the base, divided above into papillose convolute stigmas. [M. T. M.]

**DISTEGOCARPUS**. A name sometimes given to a few Japanese species of hornbeam, *Carpinus*, which differ from the others in having the bracts of the male catkins narrowed into a stalk. In other respects they are very like the common hornbeam of our shrubberies. [A. A. B.]

**DISTEPHANUS**. A genus of shrubs of the composite family from Mauritius and Madagascar, nearly related to *Vernonia*, and differing in having appendiculate apices to the scales of the involucre. Of the three known species, the most common is *D. populifolius*, a bush with stalked oval pointed leaves covered on both surfaces with soft white pubescence. The flower-heads, each about half an inch in diameter,

are numerous, and disposed in terminal corymbs; the florets being numerous and all tubular. [A. A. B.]

**DISTICHIA.** A genus of *Juncaceæ*, from elevated table-land in Peru, forming small tufted plants with dichotomous stems, subulate distichous leaves sheathing at the base, and a six-parted perianth with three stamens. [J. T. S.]

**DISTICHIS.** A name at one time applied to a few terrestrial orchids of India and Mauritius, now shown by Dr. Lindley to belong to *Liparis*. [A. A. B.]

**DISTICHOS.** When parts are arranged in two rows, the one opposite to the other, as the florets of many grasses.

**DISTICTIS.** A genus of *Bignoniaceæ*, containing a few species, natives of America and the West Indies. They are slender climbing shrubs, with opposite petiolate leaves, sometimes trifoliate, more generally doubly bifoliate; the apex of the petiole is commonly produced into a tendril. The white flowers are in terminal few-flowered racemose panicles, the corolla funnel-shaped, cut into five unequal roundish lobes, and enclosing four didynamous stamens, with the filaments knee and hairy on the inner surface of the angle; the fifth is sterile. [W. C.]

**DISTRACILE.** Divided into two parts as if torn asunder, like the connective of some anthers.

**DISTYLIS.** A genus of *Goodeniaceæ*, found on the West coast of Australia, and containing only a single species. It is distinguished by having a five-parted calyx adnate to the ovary; a five-parted spreading somewhat bilabiate corolla, the segments of which have winged margins and the tube cleft behind. There are five distinct stamens and a bipartite style. The fruit is a capsule, which is crowned by the permanent calyx. *D. Bernardina* is an annual plant, with alternate toothed leaves, and yellow axillary solitary flowers on long footstalks. [R. H.]

**DISTYLUM.** A genus of *Hamamelidææ*, of two or three species of evergreen trees, natives of China, Japan, and Khakya. The flowers are sometimes perfect, having stamens and pistils; while others have stamens only or pistils only. One marked character implied by the name, is the presence of two cylindrical erect appendages, the styles, which remain attached to the fruit. [G. L.]

**DITASSA.** A considerable genus of *Asclepiadaceæ*, containing nearly forty species of small twining or erect undershrubs, natives of tropical America. They have opposite coriaceous leaves, and small whitish interpetiolar flowers, either solitary or umbellate, with rotate five-cleft corollas; the staminal crown double, its outer whorl consisting of five linear or ovate-acuminate lobes; and its inner of five generally shorter leaflets opposite the outer lobes; the foli-  
cles are long, round, and smooth. [W. C.]

**DITAXIS.** A genus of *Euphorbiaceæ*, comprising about seven species, which are found in various parts of America, south of Mexico. They are white-barked shrubs, with alternate entire or finely-toothed lance-shaped or oboval leaves, and have small green flowers, either male and female on the same, or on different plants, and arranged in little axillary racemes or cymes. The males have a calyx of five deep divisions, five fringed petals, and ten stamens arranged in a candelabra-like manner in two tiers, their filaments united below into a column, round the base of which is a disk of five glands; the females are nearly similar, having calyx and corolla; and a three-lobed hairy or nearly smooth ovary, crowned with a three-forked style. A purplish colouring matter is found in the leaves and flowers of some species. The calyx-leaves do not overlap in the buds, this serves to distinguish the genus from *Jatropha* and other of its allies. [A. A. B.]

**DITTANDER.** *Lepidium latifolium*.

**DITTANY.** *Cunila mariana*. —, **BASTARD.** *Dictamnus Frazinella*. — **OF CRETE.** *Origanum Dictamnus*.

**DIURNAL, DIURNUS.** Enduring but for a day, as the flower of *Tigridia*.

**DIURIS.** A genus of terrestrial tuberous-rooted orchids found in Australia and Tasmania. They are slender herbs, having stems one to two feet high, furnished below with several grassy leaves, and terminating in a loose raceme of pretty flowers, which are usually of a rich yellow colour marked with purple spots; more rarely white or purple. The two lateral sepals are long and narrow, suggesting the generic name—from the Greek, signifying two tails. The lip is trilobed, and the column is furnished on either side with a short erect petal-like appendage. Four of the species are well represented in Dr. Hooker's *Flora of Tasmania*. [A. A. B.]

**DIVARICATE, DIVARICATING.** Straggling, spreading abruptly, and at an obtuse angle, such as 140°.

**DIVERSIFLOROUS.** When a plant or inflorescence bears flowers of two or more sorts.

**DIVIDIVI.** The astringent pods of *Oesalpinia coriaria*.

**DIVI LADNER.** A Cinghalese tree, *Ta-bernemontana dichotoma*.

**D'JURNANG.** A natural secretion of the fruit of *Calamus Draco*, commonly known as Dragon's-blood.

**DOBERA.** The latinised form of an Arabic name for a tree with oppositely-stalked leaves, whose stalks are thickened, and of a yellow colour, and whose flowers grow in terminal panicles, and have a four-toothed calyx, four petals, and four stamens with the filaments combined below into a tube, and having four little scales between them and the petals; the ovary is

superior, and becomes an ovate fleshy one-seeded edible warted fruit. The genus is referred to the *Salvadoraceae*. [M. T. M.]

**DOBINEA.** An Eastern Himalayan bush of the maple family. It grows to about ten feet in height, and has opposite stalked lance-shaped or oval toothed leaves, and minute flowers, male and female on the same plant, disposed in long terminal panicles. The males have a four-toothed bell-shaped calyx, four oblong clawed petals, and eight stamens. The females are quite naked, and sit on the middle of a thin yellowish beautifully-veined bract, which is nearly round, and about half an inch in diameter. The circumstance of the female flower arising from near the middle of a veined bract is highly curious, and not paralleled in the family, nor is it met with in any family more nearly related than that of the lime tree. [A. A. B.]

**DOCK.** The common name for *Rumex*. — **GROVE.** *Rumex Nemolopanthum*. — **WATER.** *Rumex Hydrolapathum*.

**DODARTIA orientalis** is an erect glabrous herb with stiff rush-like very spreading branches, and few small leaves, forming a genus of *Scrophulariaceae*, with flowers much like those of the smaller *Antirrhinum*s, but with a globular capsule opening in two short nearly equal valves. It is a native of the dry saline steppes of southern Russia.

**DODDER.** *Cuscuta*.

**DODDER-CAKE.** An oil cake made from the refuse of *Camelina sativa*.

**DODDER-LAURELS.** A name applied by Lindley to the *Cassythaceae*.

**DODECA.** In Greek compounds = 12.

**DODECAS.** A genus of *Lythraceae* from Surinam. It consists of glabrous shrubs with four-angled branches, opposite oblong-obovate entire leaves, and axillary usually one-flowered peduncles; the calyx is urceolate with a four-cleft spreading limb, the petals four, small and round, and the stamens twelve. [J. T. S.]

**DODECATHÉON.** A genus of *Primulaceae*, known by the reflexed segments of the deeply-cleft corolla, and the cylindrical capsule opening at the apex by five teeth. They are smooth perennial herbs, with fibrous roots, and rosettes of oblong or obovate root leaves; the scape is simple, bearing an umbel of large nodding rose-purple or white flowers, with long reflexed segments, and five short monadelphous filaments with long anthers which are exerted and form a slender cone. The well-known American Cowslip, *D. Meadia*, grows in woods in the warmer parts of North America. In the Western States, where it is more common, it is called the Shooting Star. The name, signifying twelve divinities, is one of fanciful application. [J. T. S.]

**DODONÆA.** A genus of viscous shrubs

of the order *Sapindaceae*, comprising about fifty species, the greater proportion of which are found in extratropical Australia, and the remainder are thinly scattered over other tropical countries. Few of them exceed ten feet in height, and almost all have their leaves more or less covered with a clammy gum. In the most commonly diffused group these organs are lance-shaped or spatulate; in another they are linear; in a third they are wedge-shaped and toothed; while in a fourth they are pinnate, made up of numerous little wedge-shaped or linear leaflets. The apetalous flowers are unisexual or polygamous, arranged in axillary or terminal racemes or panicles. The fruits are membranous, with their angles produced into thin papery rounded wings. The leaves of *D. viscosa*, one of the most widely diffused species, have a somewhat sour and bitter taste, and the plant is from this circumstance, called in Jamaica, Switche Sorrel. According to Dr. Bennett, this plant is known in Tahiti as Apri, and 'fillets of it were once used for binding round the heads and waists of victors after a battle, and during the pursuit of the vanquished.' The leaves of *D. Thunbergiana*, a native of South Africa, are said to be used against fevers, and as a purgative. The genus bears the name of Dodonæus, a Belgian botanist and physician of the sixteenth century. [A. A. B.]

**DODRANS** (adj. **DODRANTALIS**). Nine inches, or the space between the thumb and the little finger separated as widely as possible.

**DOGBANES.** A name given by Lindley to the *Apocynaceae*.

**DOGBERRY-TREE.** *Cornus sanguinea*.

**DOG MERCURY.** *Mercurialis perennis*.

**DOG-POISON.** *Aethusa Cynapium*.

**DOG'S-BANE.** A common name for *Apocynum*; also *Aconitum Cynoctonum*.

**DOG'S-CHOP.** *Meembryanthemum caninum*.

**DOGWOOD.** *Cornus sanguinea* and *Rhamnus Frangula*. — **AMERICAN.** *Cornus florida*. — **BLACK.** *Piscidia orthogynensis*. — **JAMAICA.** *Piscidia Erythrina*. — **NEW SOUTH WALES.** *Jacquinia scoparia*. — **TASMANIAN or VICTORIAN.** *Bedfordia salicina*. — **WHITE.** *Piscidia Erythrina*.

**DOH.** A Javanese name for the horse-hair-like fibres of the Gomuti palm, *Saguerus saccharifer*.

**DOLABRIFORM.** Fleahy, nearly straight, somewhat terete at the base, compressed towards the upper end; one border thick and straight, the other enlarged, convex, and thin.

**DOLIA.** A genus of *Nolanaceae*, containing a few South American littoral plants with the habit of some of the smaller maritime *Chenopodiaceae*. Heath-like branched shrubs with fleshy linear

leaves and small flowers, with salver-shaped corollas, and eight or ten ovaries variously united. [J. T. S.]

**DOLICHANDRA.** A small genus of *Bignoniaceae*, inhabiting extratropical parts of Brazil, and remarkable as the only known climber of the order having a capsule the partition of which runs in a contrary direction to that of the valves. In habit it much resembles *Macfadena*, the branches being climbing, the leaves either trifoliate or conjugate and furnished with tendrils, and the flowers in the axils of the leaves; the calyx is spathaceous; the corolla is long and tubular, whilst the stamens (four in number with the rudiment of a fifth), as well as the stigma, project beyond the corolla. The typical species is *D. cynanchoides*. [B. S.]

**DOLICHANDRONE.** A small genus of *bignoniaceous* trees, inhabiting tropical Asia and Australia. Their leaves are either simple or impari-pinnate, and the leaflets either ovate, lanceolate, or, in *D. filiformis* of New Holland, reduced to very narrow linear bodies. The flowers are white and arranged in panicles; the calyx is spathaceous, and the corolla has a tube twice or thrice the length of the calyx; the stamens are four in number, with the rudiment of a fifth; the fruit is a flat capsule opening at the margin, but being divided by a partition, which runs contrary to the direction of the valves. Some of the Asiatic species yield timber. [B. S.]

**DOLICHOS.** A genus of leguminous plants, consisting of herbaceous or shrubby species, which for the most part have twining stems. As many as 60 or 70 forms have been described, but the number of species is probably much fewer. They are distributed throughout the tropical and temperate regions of Asia, Africa, and America. The plants, formerly called *D. Lablab* (*Lablab vulgaris*), *D. sinensis* (*Vigna sinensis*), *D. bulbosus* (*Pachyrhizus angulatus*), *D. Outang* (*Vigna Outang*), all produce edible legumes and pulses. The species of *Dolichos* have trifoliate leaves; and their flowers are produced, either solitary or in racemes, from the bases of the leaves. The pods are generally more or less flattened, and neither winged nor prominently nerved.

*D. sesquipedalis* is a native of the West Indies and tropical South America, but is cultivated in warm sheltered places in France, and some parts of the south of Europe. The French call it *Dolich asperge*. It has smooth twining stems, six or eight feet in height, with large egg-shaped pointed leaflets, and yellowish-green flowers. Its pods are from a foot to a foot and a half long, cylindrical and pendulous, and of a shining light-green colour, containing from seven to ten kidney-shaped seeds. The young or green pods of this plant are cooked and used as a table vegetable, and, being without the tough parchment-like skin of the common pea-pod, they form an excellent dish. *D. tuberosus*, a native of Martinique, has a fleshy tu-

berous root, which the inhabitants cook as an article of food, and they also use the pulse for the same purpose. It has a shrubby stem, with twining branches, and leaves with roundish-pointed leaflets. *D. uniflorus* is an annual plant having an erect stem and twining branches, with leaves composed of three egg-shaped leaflets, and yellow flowers, which produce narrow flat pods curved something like a reaper's sickle, and covered with soft hairs. This plant is a native of the East Indies, where it is grown for food under the name of Horse Gram. [A. S.]

**DOLIOCARPUS.** A small genus of *Ellie-niads*, consisting of about eighteen species, nearly all of which are climbing shrubs, inhabitants of tropical South America. It is closely allied to *Delima*, but the leaves are not rough, and the flowers are produced from the sides instead of the ends of the branches; besides which, the fruit is pulpy and does not burst open when ripe. *D. Cuneata* is a climbing shrub with woody stems, having oblong pointed leaves, and small white flowers collected into dense heads, a portion only perfect, the rest being male or female. The fruit is a small fleshy shining berry. [A. S.]

**DOLOMIÆA.** A genus of *Compositæ*, nearly related to *Saussurea*, but differing in the pappus-hairs being rough instead of feathery. *D. macrocephala*, the only known species, is a perennial stemless herb found at elevations of 10,000 to 13,000 feet in N. W. India; it has pinnately parted much-lobed leaves clothed with white down beneath, while the centre of the plant is occupied by a cluster of shortly-stalked flower-heads, each an inch or more in length, and furnished with an involucre of numerous lance-shaped scales, which enclose many purplish tubulous florets. According to Royle, it is used by the inhabitants of the hills in their religious ceremonies, and is called by them Googlan. [A. A. B.]

**DOMBA-OIL.** A fragrant oil obtained from the seeds of *Calophyllum Inophyllum*.

**DOMBEYEA.** A tribe of plants included in the natural order *Sterculiaceæ*. The petals are flat; stamens fifteen to forty, united at their base, usually some of them sterile. Ovary with five or many cells, having two or more ovules in each. Fruit a capsule; embryo within fleshy albumen. Trees or shrubs growing in tropical regions of the Old World. In this tribe are included the genera, *Pentopetes*, *Kutia*, *Dombeya*, *Melastoma*, *Astragalus*, and a few others. [J. H. B.]

**DOMBEYA.** A genus of handsome African shrubs or small trees of the *Sterculia* family, a goodly number of them cultivated in plant stoves for the sake of their handsome foliage and flowers. They are found in the greatest number in Madagascar and Mauritius, and extend as far north as Abyssinia. The leaves are often like those of the maple or the plane, but

in some are much smaller, heart-shaped and nearly entire; while the flowers are borne in axillary cymes or umbels, each flower being supported by an involucre of three small leaves which fall early. It has a five-parted calyx, five petals, and fifteen to twenty stamens, accompanied by five filiform or strap-shaped sterile ones, all slightly united at the base into a ring. The fruits are little hairy five-celled capsules. Ropes and various sorts of cordage are made in Madagascar from the bark of *D. platanifolia*, as well as from some other of the species. *D. mollis* has large heart-shaped leaves, three-lobed at the apex, covered with a soft dense down, and its rose-coloured flowers with narrow petals, are disposed in dense stalked umbels, and smell like hawthorn. The genus bears the name of M. Dombey, a French botanist and traveller in S. America. [A. A. B.]

**DOMPTE-VENIN.** (Fr.) *Vincetoxicum officinale*.

**DONALDIA.** A genus of S. American begonias whose staminate flowers have two, and pistillate five sepals; anthers elongated, with a dark-brown small connective, the filaments not united; the style is persistent, its branches furnished with a continuous papillose band, which makes three spiral turns; the placentas are split lengthwise. There are two species, viz., *D. ulmifolia* and *D. Ottonis*, both formerly included in *Begonia*. [J. H. B.]

**DONATIA.** A genus of *Saxifragaceae* from the Straits of Magalhães: small herbs resembling *Saxifraga groenlandica*, with tufted stems, and thick linear lanceolate obtuse glabrous leaves having wool in their axils; flowers, terminal, sessile, white, with the calyx tube adhering to the ovary, and the limb four or five-toothed, and having eight or ten petals. [J. T. S.]

**DONDIA.** *Hacquetia*.

**DONDISIA.** The name applied to an Indian shrub of the order *Cinchonaceae*. The tube of the corolla is lined with rigid hooked hairs; its limb is divided into five acute lobes; stamens five, inserted into the throat of the corolla; style thread-like dilated in the middle; stigma ovate. [M. T. M.]

**DONIA.** The name sometimes applied to an American genus of yellow-flowered composite plants, better known as *Grindelia*. It has been also applied to *Cleistanthus*.

**DONKELERIA.** A garden name sometimes applied to *Centradenia*.

**DONZELLIA.** A genus of polypetalous dicotyledons, established by Tenore on a shrub grown in the plant-houses in the Botanic Garden of Naples. It is, however, so imperfectly described, that it has not been recognised in our own collections.

**DOOB or DOORBA.** Indian names for *Cynodon Dactylon*, which is there a fodder grass.

**DOODIA.** A group of polypodiaceous ferns related to *Woodwardia*, with which they are incorporated by many modern botanists notwithstanding considerable differences of size, habit, and aspect. They differ from *Woodwardia* chiefly in having superficial instead of sunken sori, and in having the indusium less convex or vaulted, and more lunate. These differences seem rather to indicate sectional than generic distinction. [T. M.]

**DOOGHAN.** *Myristica spuria*.

**DOOLOO.** A kind of rhubarb.

**DOONA zeylanica** is a large resinous dipteraceous tree with rose-coloured flowers in panicles. Three of the five sepals of its flowers are larger than the other two, and increase in size after the fall of the corolla; the petals are united at the base; there are sixteen stamens in two rows with dilated filaments, and four-sided anthers with a club-shaped appendage; ovary three-celled, six-seeded. [M. T. M.]

**DOOPADA.** Indian Copal or Piney Varnish, a resin obtained from *Vateria indica*.

**DOORA.** *Sorghum vulgare*.

**DOORNIA.** A genus of *Pandanaceae*, native of Bourbon or Madagascar, having the appearance of screw pines. The female flowers, which alone are known, are seated on a branched spadix, and consist of ovaries arranged in groups of three or four. The fruit consists of a number of fibrous or woody drupes arranged in groups, and separated from neighbouring parcels by a fibrous material. These collections of drupes form six-sided conical masses on a common stalk. [M. T. M.]

**DOORWA.** *Cynodon Dactylon*, a fodder grass of India.

**DOOR-WEED.** *Polygonum aviculare*.

**DORADILLE.** (Fr.) *Asplenium*.

**DORATOMETRA.** A genus of begonias, consisting of East Indian undershrubs, whose staminate flowers have four, and whose pistillate flowers five sepals; the anthers are short, rounded on both sides, with united filaments; the style is persistent, its branches surrounded by a continuous papillose band which makes two spiral turns; the placentas are undivided and stalked, their transverse sections cordate-ovate acute. The seed-vessels have three equal wings, and are attenuated at the apex. There is only one species, *D. Wallichiana*, which has been separated from *Begonia*. [J. H. B.]

**DORELLE.** (Fr.) *Limosyris vulgaris*.

**DOREMA.** A genus of *Umbelliferae* or *Aptaceae*, comprising certain Persian herbs with branching proliferous umbels, and flowers imbedded in a woolly substance, but having no involucre; the calyx is slightly toothed at the margin. The fruit is compressed, surrounded by a broad border, and marked on the back by five ridges, the three central ones thread-like,

and more prominent than the two lateral oil channels four, on the inner surface of each half of the fruit. *D. ammoniacum* furnishes the drug now known as ammoniacum. It is a native of Persia, and abounds in a milky juice which exudes upon the slightest puncture being made, and dries upon the stem in little rounded lumps, or tears as they are called. This gum resin is used as a stimulant expectorant, and as an external application, but its powers are not great. The ammoniacum of the ancients is said to have been the produce of *Ferula tingitana*. [M. T. M.]

**DORINE.** (Fr.) *Chrysosplenium*.

**DORITIS.** A small genus of caulescent epiphytal orchids found in Cochin-china and New Guinea. They have ovate or oblong leaves, and axillary panicles of small white or purple flowers. The sepals are oblong, the lateral ones decurrent with the column; the petals, nearly equal and wedge-shaped; the lip tri-lobed, with a long claw attached by an elastic joint to the produced foot of the column, and the two bilobed pollen masses are borne on the end of a long slender caudicle attached to an ovate gland. [A. A. B.]

**DORONICUM.** A genus of herbaceous perennials belonging to the order of compound flowers. The florets of the ray are destitute of a pappus, while those of the disk have a hairy pappus. *D. Pardalianches*, though enumerated among British plants, is not generally considered to be indigenous to the soil. It is to be found in waste ground near houses in several parts of England, and yet more frequently in Scotland. Under the name of *Pardalianches*, or *Leopard's-bane*, it had the reputation of possessing 'virtues so ambiguous,' says Gerard, 'and so doubtful: yea, and so full of controversies, that I dare not to commit that to the world which I have read. It is reported and affirmed that it killeth panthers, swine, wolves, and all kinds of wild beasts, being given them with flesh. Theophrastus saith that it killeth cattle, sheepe, oxen, and all four-footed beasts within the compass of a day: yet he writeth further, that the roote being drunke is a remedie against the stings of scorpions, which sheweth that this herbe or the roote thereof is not deadly to man, but to divers beasts onely, which thing also is found out by trial and manifest experience: for Conradus Gesnerus, a man in our time singularly learned, and a most diligent searcher of many things, sheweth that he himself, in a certain epistle written to Adolphus Occo, hath oftentimes inwardly taken the roote hereof Greene, drie, whole, preserved with honie, and also beaten to powder, and that even on the very same day in which he wrote these things, he had drunke, with warme water, two drams of the rootes made into fine powder, neither felt he any hurt thereby.' The fact appears to be that the leopards and other 'four-footed beasts' were poisoned with aconite, one

of the author's synonyms for *Pardalianches*: while the human experimentalist found the powdered root of the latter plant inert. *Leopard's-bane* is a robust plant, with large roughish leaves and conspicuous yellow flower-heads. There are several species natives of Europe or Asia, some of which are cultivated as ornamental plants. French, *Doronic*; German, *Gemsenwurz*. [C. A. J.]

**DORSIFEROUS.** Bearing something on the back.

**DORSTENIA.** A genus of moraceous plants named after Dorsten, a German author. It is associated with mulberries

*Dorstenia ceratosanthes*.

and figs. The genus has a flat and somewhat concave receptacle bearing numerous flowers. The staminate flowers have no perianth, but two or more stamens. The pistillate flowers are also without a perianth; the ovary is one-celled with a lateral style and blind stigma, containing one ovule. The fruit-bearing receptacle becomes somewhat succulent. There are thirty-six known species. They are herbaceous plants found in tropical America. They have radical leaves which are palmate or pinnatifid, and the receptacle terminating the scape is quadrangular or rounded, or occasionally linear and forked. *D. Contrayerva* and other species have a stimulant and tonic rhizome, which is used medicinally under the name of *Contrayerva-root*. [J. H. B.]

**DORSUM.** The back of anything; in the parts of the flower, that surface which looks towards the outside.

**DORYANTHES.** A genus of New Holland *Amaryllidaceae*, having what Herbert calls imperfect bulbs, a tall straight stem twenty feet high, springing from an aloelike tuft of broadly ensiform-spreading basal leaves, the stem itself clothed with much smaller appressed ones, and terminated by a bulky compound flower-head composed of crimson flowers emerging from great half-sheathing crimson bracts. The perianth is six-parted and funnel-shaped, the segments nearly equal; the six stamens, having long erect anthers, are inserted into the base of the perianth seg-

ments; the style is three-furrowed, with a three-cornered stigma; and the ovary grows into a three-celled turbinate oval capsule.

*Doryanthes excelsa.*

It is a fine plant, sometimes met with in cultivation. [T. M.]

**DORYONIUM.** A genus of *Leguminosae*, comprising a few erect twiggy herbs, nearly related to *Lotus*, from which they may be recognised by the keeled petal being obtuse, not beaked. Their leaves are sessile, and made up of three to five linear leaflets about half an inch long. The minute pink or white flowers are collected into round stalked heads, a good deal like those of the white clover, but smaller. The pods are turgid, scarcely larger than the calyx, and contain two to four seeds. The species are confined to the countries bordering on the Mediterranean. [A. A. B.]

**DORYONOPSIS.** A genus of *Leguminosae*, with the habit of *Dorycnium*, but differing in the stamens being of equal instead of unequal length, as well as in the pod not bursting when ripe. The only known species is *D. Gerardii*, found in the south of Europe, a perennial branching herb one to two feet high, having slender stems furnished with unequally-pinnate vetch-like leaves, the twigs terminating in little clover-like heads of small rosy flowers. The minute one-seeded pod is quite hidden in the calyx. [A. A. B.]

**DORYOPTERIS.** A name proposed for a group of ferns belonging to the *Pteridea*, and having uniformly reticulated venation, which is sunk in the substance of the frond, and is on that account generally obscure. The genus is not, however, materially different from *Libocrochia*, with which it is now frequently united. [T. M.]

**DORYPHEORA.** The generic name of the *Sassafras* tree of New South Wales,

which belongs to the *Atherospermaceae*, and is somewhat nearly related to the *Sassafras* of Tasmania, *Atherospermum moschatum*. It differs, however, in having the anthers prolonged into a tail-like process. *D. Sassafras*, the only species of its genus, grows to a fine asymmetrical pyramidal tree of sixty or one hundred feet high, with a diameter of two to three feet; and is furnished with opposite smooth lance-shaped or elliptical toothed leaves. The flowers are small, perfect, and three together, supported on axillary peduncles shorter than the leaves, and enveloped by two silky bracts, each with a calyx border of six divisions and twelve stamens, six fertile and six sterile, the fertile ones having the anthers prolonged into a tail. The ovaries are numerous and become one-seeded nuts, the styles remaining attached to the ripe fruits in the form of feathery awns. The leaves, bark, and wood emit an agreeable aromatic odour which, when fresh, is said to resemble fennel. The bark is also said to be used by the colonists as a tonic, and is much esteemed. The wood is of little value, being extremely soft and light. It is sometimes used for making packing cases and similar articles. [A. A. B.]

**DORYSTIGMA.** A genus of *Solanaceae*, consisting of low-growing herbaceous plants, with solitary extra-axillary flower-stalks; the corolla is funnel-shaped, hairy within, the anthers green, concealed within the corolla; the ovary is two-celled. They are natives of the Andes. [M. T. M.]

**DOSSINIA marmorata** is the name of a beautiful little Bornean orchid cultivated in gardens for the sake of its olive-green velvet-like leaves, the nerves and nervelets of which are of a paler colour, thus giving them a marbled appearance, whence the specific name. The creeping stems have five or six ovate leaves, two or three inches in length by one or two broad; and the flower spike is about a foot high, bearing a number of small white flowers tinged with pink. The plant is sometimes called *Cheirostylis* or *Macodes marmorata*, as well as *Anæctochilus Lowii*; it differs from *Anæctochilus* in the absence of a bearded fringe to the lower part of the lip, as well as in the boat-shaped process of the column. It is dedicated to E. P. Doassen, a Belgian botanist. [A. A. B.]

**DOTHIDEA.** A large genus of sphaeriaceous *Fungi*, differing from *Sphæria* and its more immediate allies in not having the walls of the fruit-bearing nucleus so perfectly developed or so distinct in colour and structure from the stroma. *D. ribesia* is one of our commonest *Fungi*, forming little black spots on the dead stems of currants, &c.; the sporidia in *Dothidea* seldom acquire complicated forms like those which make *Sphæria* so abundant a source of objects for the microscopist. [M. J. B.]

**DOTTED.** Furnished with transparent receptacles of oil, looking like dots; marked with punctures.

**DOUBLE-BEARING.** Producing twice in the same season.

**DOUBLY.** Having a form or structure repeated; doubly-toothed = teeth themselves toothed, and so on.

**DOUCE-AMÉRE.** (Fr.) *Solanum Dulcamara*.

**DOUCETTE.** (Fr.) The common *Valerianella*, which were called *Valeriana locusta*, by Linnaeus.

**DOUCIN.** (Fr.) Certain varieties of *Pyrus Malus*.

**DOUGLASIA.** A genus of primworts, distinguished from its allies by the funnel-shaped corolla, the tube of which is partly dilated. The name was given by Dr. Lindley as an appropriate compliment to David Douglas, a well-known botanical collector, to whose energy and zeal we owe the introduction of many interesting plants. *D. nivalis*, which is the best known species, was discovered by Douglas not far from the sources of the Columbia river, near snow, at an elevation of 12,000 feet; another, *D. arctica*, was found by Sir J. Richardson, on the Arctic shore between the Mackenzie and Coppermine rivers. These plants have forked and closely tufted stems, linear leaves, and are covered with numerous short stiff hairs. [G. D.]

**DOURA, or DURRA.** The great Millet, *Sorghum vulgare*.

**DOUVE, GRANDE.** (Fr.) *Ranunculus Lingua*. —, **PETITE.** *R. Flammula*.

**DOUX-GUILAUME, or also DOUX-JEAN.** (Fr.) *Dianthus barbatus*.

**DOUZE DIEUX.** (Fr.) *Dodecatheon Meadia*.

**DOVEA.** A genus of *Restiaceae*, consisting of South African aedge-like plants, distinguished by their simple one-celled anthers, three-celled capsule opening at the angles, and three (rarely two) sessile stigmas. The rhizome is creeping, scaly; the stems wand-like with remote sheaths; the flowers discolorous. [J. T. S.]

**DOVE-FLOWER.** *Peristeria*.

**DOVE'S-FOOT.** *Geranium dissectum*.

**DOWNY.** Covered with very short weak close hairs.

**DRABA.** Whitlow Grass. An extensive genus of small annual or perennial herbaceous plants of the Cruciferous order, among which they are distinguished by having the pod compressed, with the dissepiment in the broadest diameter, and numerous seeds in each cell. They are most numerous in the cold mountainous countries of Europe: a few of them are natives of America, and several of Great Britain. Of these last, *D. cistoides* grows on walls near Swansea, and is remarkable for its bright yellow flowers, and glossy leaves margined with hairs. It is a pretty plant, well adapted for rock-work, as, indeed, are

several of the foreign species, being of humble growth, and tufted habit, and made conspicuous by their white or yellow flowers, which, though small, are numerous and bright. Of the other British species, *D. verna*, called also *Erophila vulgaris*, an humble little annual with scanty foliage and inconspicuous white flowers, is not without interest from its appearing very early in the year. It grows on wall-tops and dry banks. Fr. *Drave*; German, *Hungerblümchen*. [C. A. J.]

**DRACÆNA.** A genus of monocotyledons of the order *Liliaceae*, remarkable for the elegant palm-like character assumed by the greater number of the species. The genus as formerly constituted was a rather extensive one, but it has lately been remodelled by Dr. Planchon, who removes from it all but the *Dracena Draco*, or Dragon tree of Teneriffe; and refers the other species to *Dracaenopsis*, *Cordylina*, *Calodracon*, *Chariswoodia*, and *Cohnia*. Thus limited, *Dracena* is distinguished by having a bell-shaped perianth deeply separated into six equal segments, furnished with six stamens inserted at the base of the segments, and succeeded by a fleshy berry containing one, two, or rarely three seeds, the ovary, which is three-celled, with a single ovule in each cell, seldom perfecting all of them.

*D. Draco* has a tree-like stem, simple or divided at the top, and often when old becoming much branched, each branch terminated by a crowded head of lanceolate linear entire leaves of a glaucous green colour, which leaves embrace the stem by their base, and on falling off at maturity leave a ring-like cicatrix or scar. The flowers form a large terminal panicle, and are individually small and of a greenish-white colour. As seen in our stoves and green-houses, the plant is usually unbranched, being in its 'first age' or infancy, which lasts in its native country from twenty-five to thirty years. The 'second age,' or period of maturity and reproduction, and the 'third age,' or period of decay, are of indefinite extent. During the former of these, the scars of the leaves disappear, and the thickness of the trunk is at length increased by the formation of branches, and the consequent deposit of new matter; while in the latter stage, aerial roots appear, and glandular excrescences are formed. It is only when of great age that it branches. This tree derives its common name from a resinous exudation known in commerce as dragon's-blood. The resin has been found in the sepulchral caves of the Guanches, and has hence been supposed to have been used by them in embalming their dead. It appears at one time to have formed a considerable branch of export from the Canaries, and has never wholly fallen into disuse. The once famous colossal Dragon tree at the town of Orotava in Teneriffe was a giant amongst the plants of this type of vegetation, being according to Møyen seventy feet high, and forty-eight feet in circumference, with an antiquity which

must at least be greater than that of the pyramids. The trunk of this tree was hollow, and might be ascended by a staircase in the interior up to the height at which it began to branch. Near the ground Le Duc found it to be seventy-nine feet in circumference. Humboldt mentions that when he saw it, it had the same colossal size (16 ft. diameter) which it had when the French adventurers, the Bethencourts, conquered these gardens of the Hesperiades in the beginning of the fifteenth century. A tree like this of slow growth, which for centuries changed so little, may well be believed to have possessed great antiquity. Unfortunately it was totally destroyed in a hurricane which occurred in 1867. [T. M.]

**DRACÆNOPSIS.** A genus of *Liliaceæ*, separated from *Dracæna* by Dr. Planchon, and consisting of plants agreeing in the following peculiarities: a six-parted marcescent campanulate perianth, with the segments biseriate; six stamens inserted at the base of the perianth segments; a three-celled ovary with many ovules in each cell; and a pea-shaped berry containing several seeds in each of its three cells. To this genus are referred *D. australis* and *D. indivisa*, two beautiful Australian arborescent species, with erect simple stems, and Yucca-like heads of crowded lanceolate-ensiform leaves. [T. M.]

**DRACOCEPHALUM.** This alarming name, literally Dragon's-head, has been given to a genus of from twenty-five to thirty species of herbaceous labiates, distinguished by having the throat of the corolla inflated, and the upper lip concave. They grow to the height of from six inches to three feet, and in habit somewhat resemble *Salvia*. *D. canariense* or *Cedronella triphylla* is better known as Balm of Gilead, a designation which it hardly merits, being a native of America and the Canaries, and having no healing properties, though the foliage is fragrant. It is distinguished by its pinkish spiked flowers, and ternate leaves. *D. Moldavica* is an annual with reddish stems, oblong blunt leaves, and whorled purplish blue or white flowers, forming a leafy spike. *D. virginianum*, also called *Physostegia*, bears numerous large light bluish flowers, arranged in four ranks, of which, it is said, 'the position may be altered at pleasure, and as they are placed, so they will remain for several hours.' Fr. *Dracocéphale*; Ger. *Drachenkopf*. [C. A. J.]

**DRACONTIUM.** A genus of *Oronticeæ*, comprising certain tropical species, with a thick fleshy rhizome, whence proceed a number of stalked pedate leaves, a sessile spadix with a hooded spathe, and very fetid flowers, which are hermaphrodite and have a five to eight-cleft perianth; stamens five to eight, the anthers with two transverse cells; ovary three-celled, each cell containing a single ovule; style awl-shaped; berries distinct, with one to three seeds. *D. polyphyllum*, a native of some parts of India, Japan, &c., possesses power-

ful stimulant properties. In Guiana it is considered as a remedy against the Labaeri snake, which it resembles in the colour of its spotted leaf-stalks. [M. T. M.]

**DRACOPHYLLUM.** A genus of *Epacridaceæ*, which is distinguished by having a calyx of five coriaceous leaves; a broad-tubed glabrous corolla with five spreading lobes curved in at the point; and the stamens inserted on the corolla in the New Zealand species, hypogynous in those of Australia and New Caledonia; the ovary is five-celled with five glands at its base. They have narrow grassy leaves sheathing at the base, and white flowers forming a racemose, spicate, or paniculate inflorescence. Most of them are natives of New Zealand, where their peculiar habit gives a striking character to the scenery. Some few are tall trees, the others only shrubs. [R. H.]

**DRACOPIS.** A genus of annual composite plants consisting of one N. American species, *D. amplexicaulis*, which has oblong-cordate stem-clasping leaves, and conspicuous flower-heads with a yellow ray and prominent black disk. It is an old garden plant, and is allied to *Rudbeckia*. [T. M.]

**DRACUNCULUS.** A genus of *Araceæ*, consisting of certain South European plants, with tuberous rhizomes and pedate leaves, scarcely differing from *Arum*, except in the upper part of the spathe being flat not convolute. One species, *D. vulgaris*, the old *Arum Dracunculus*, is common in gardens, where its pedately-divided leaves and spotted stems render it very ornamental. [M. T. M.]

**DRAGON.** *Dracunculus vulgaris*; also applied to the oronticeous genus *Dracontium*. — GREEN. *Arisæma Dracontium*.

**DRAGONNE.** (Fr.) *Tulipa turcica*.

**DRAGONNIER.** (Fr.) *Dracæna Draco*.

**DRAGON ROOT.** *Arisæma atrorubens*; also an American name for *Arisæma Dracontium*.

**DRAGON TREE.** *Dracæna Draco*.

**DRAGON'S-BLOOD.** A dark-red astringent resinous secretion of the fruit of *Calamus Draco*; another kind is obtained from *Dracæna Draco*. *Ecataphyllum monstaria* yields a similar resinous product.

**DRAGON'S-EYE.** *Nephetium Longanum*.

**DRAGON'S-HEAD.** A common name for *Dracoccephalum*. —, FALSE. *Physostegia*.

**DRAGON'S-MOUTH.** *Epidendrum macrochitum*.

**DRAKEA** *elastica* is a curious terrestrial orchid of West Australia with woolly roots ending in fleshy tubercles; a single orbicular leaf three-quarters of an inch across, growing quite close to the ground, and a slender erect smooth scape twelve to eighteen inches high, bearing at the apex a solitary dull-coloured flower three-quarters of an inch across. The shield-shaped labellum is placed on a long arm with a moveable joint in the middle,

and is stated by Mr. Drummond to resemble an insect suspended in the air moving with every breeze. This is the only species known. [A. A. B.]

**DRAPETES.** A genus of *Thymelaeaceae* with hermaphrodite flowers, and a coloured funnel-shaped perianth with a four-cleft limb, and no scales in its throat; stamens four, inserted on the perianth; no hypogynous scales; ovary one-celled. The fruit is a single-seeded nut, included in the base of the persistent perianth. *D. muscoides*, the only species, is found at the Straits of Magalhaens. It is a shrubby plant with opposite decussate sessile leaves. [J. H. B.]

**DRAVE.** (Fr.) *Draba*.

**DRAYTONIA.** A genus now united to *Acaurayia* (which is placed by some botanists with the dilleniads, and by others in the tea family), but differing in the styles being united to the apex. *D. rubicunda*, so called from the reddish hue of the leaves, is found in the Feejee Islands, and is the only species. It is an ornamental shrub, or sometimes tree, of forty to fifty feet high, with long alternate stalked papery oblong serrated leaves, and axillary stalked cymes of small red flowers, which have a calyx of five roundish sepals, five obovate petals, about forty stamens slightly united below, and an ovary crowned by a columnar style tipped with a three-lobed stigma. The fruit is a small capsule about the size of a pea, enclosing numerous seeds. The genus bears the name of Mr. J. Drayton, an American naturalist and artist. [A. A. B.]

**DREGEA.** A genus of *Asclepiadaceae*, containing two species, natives of Africa and Arabia. They are shrubs with opposite membranaceous leaves, and small glabrous flowers in umbels on interpetiolar peduncles. The calyx consists of five sepals, and the rotate corolla is five-cleft, with faintly emarginate lobes, while the staminal crown consists of five small kidney-shaped leaflets attached to the gynostegium. The two follicles are four-winged and divaricate, and contain few comose seeds. In habit and structure this genus is very near to *Marsdenia*; it differs from it chiefly in the structure of the staminal crown and in the tetrapterous fruit. [W. C.]

**DRIMIA.** A genus of *Liliaceae* from the Cape of Good Hope, containing bulbous herbs, with oblong orchis-like or linear root leaves, and scapes bearing a raceme of flowers, with a six-parted reflexed perianth, varying in colour in different species, being purple, yellow, white, or red, often tinged with green. The juice of the bulbs is said to be very acrid, causing blisters when applied to the skin. [J. T. B.]

**DRIMIOPSIS.** A genus of *Liliaceae* from the Cape of Good Hope, containing bulbous herbs with radical leaves, and a scape with a raceme of greenish yellow flowers,

which are bell-shaped, and have six equal stamens inserted on the perianth segments. *D. maculata* is a greenhouse bulb with spotted leaves. [J. T. B.]

**DRIMYS.** A genus of *Magnoliaceae*, consisting of trees natives of South America, New Zealand, &c. They have their carpels crowded, berry-like, and many-seeded, and the cells of the anther are separated by a thickened connective. *D. Winteri*, a native of Chili and the Straits of Magalhaens, furnishes the bark known as Winter's Bark, which both in appearance and properties is much like canella bark, but is of a darker colour internally. It is a stimulant aromatic tonic, but is seldom used. The bark was first brought to Europe by Capt. Winter in 1579, he having accompanied Sir Francis Drake to Magalhaens' Straits. In Brazil the bark of *D. granatensis* is used against colic. *D. piperita* is a native of Borneo. [M. T. M.]

**DRIMYSPERMUM.** A Malayan shrub with alternate leaves and umbellate flowers surrounded by an involucre. The perianth is coloured, tubular, with a four-parted limb; stamens eight, inserted into the throat of the perianth. The base of the ovary is surrounded by a membranous tube, the ovary itself being free, with one ovule in each of its two compartments, and crowned by a short style with a button-like stigma. Fruit berry-like, two-celled, two-seeded. It is included among the *Aquilariaceae*. [M. T. M.]

**DROGUE AMÈRE.** A bitter tincture, of which *Andrographis paniculata* is the basis; it possesses stomachic and tonic properties.

**DROP-SEED.** *Muhlenbergia diffusa*.

**DROPWORT.** *Spiraea Filipendula*; also *Potentilla Filipendula*. —, **WATER.** The common name for *Uranthe*.

**DROSERACEÆ.** (*Sundews.*) A natural order of thalamifloral dicotyledonous or exogenous plants belonging to Lindley's berberal alliance. Herbs often covered with glandular hairs. They have alternate leaves with fringes at their base, and a circinate vernation; sepals five, persistent; petals five; stamens as many as the petals, or twice or three times as many; styles three to five. Fruit a one-celled three to five-valved capsule with loculicidal dehiscence. The plants are found inhabiting marshes in Europe, India, China, Cape of Good Hope, Madagascar, North and South America, and New Holland. They have acid and slightly acrid properties. Hooker thinks that the order should be placed near the *Saxifragaceae*. Some of the Antarctic species are perigynous. The species of *Drosera* are remarkable for their glandular hairs, which are covered with drops of fluid in sunshine: hence the name of Rosolids, and of the Italian *Uguor Rosoli*, in the preparation of which a species of *Drosera* is used. Some include *Farnassia* in this order. There are seven known genera, including

*Drosera*, *Dionaea*, *Drosophyllum*, and *Aldrovanda*, and about 100 species. [J. H. B.]

**DROSERA.** A genus of plants giving name to the order *Droseraceae*, and distinguished by having five sepals, petals, and stamens, three to five-cleft styles, and a one-celled many-seeded capsule. Their most striking character, however, is connected with their leaves. These in the British species all spring from the root in a radiating manner, and in their early stage are rolled up in a circinate form like the fronds of a fern. When expanded they are somewhat concave, and are thickly set with red glandular hairs, those nearest the edge being the longest. Each hair is tipped, especially in bright weather, with a minute drop of viscid fluid, hence the name *Drosera* (from the Greek *drosos*, dew), and the English name Sundew. The hairs are not so decidedly irritable as in the allied genus *Dionaea*, but when any small fly or other insect alights on a leaf, it is held entangled, at first by the viscid fluid, and, subsequently, the hairs bend down over it until decomposition has taken place. And this is no unusual occurrence; on the contrary, one can scarcely ever examine a plant without finding the wings and legs of insects on one or more of the leaves. The viscid fluid with which the hairs are furnished, is said to be acrid and caustic, to curdle milk, and to remove warts, corns, freckles, and sunburns. It is also said to cause the rot in sheep. The sanitary virtues ascribed to it may be real or imaginary; but with respect to its mischievous effects on sheep, there can be no doubt that where Sundew grows, there flocks are not likely to fatten, for the herbage with which it is associated is mostly moss, rushes, cotton-grass, and other juiceless weeds. There are three species of Sundew indigenous to Britain, which differ in the shape and size of their leaves, and agree in having small inconspicuous flowers on a leafless wiry scape. Some of the foreign species have leafy stems. The hairs of *D. lunata* are said to close upon insects which alight upon them. French, *Rossoile*; German, *Sonnen-tau*. [C. A. J.]

**DROSOPHYLLUM.** A singular half-shrubby plant belonging to the *Droseraceae*, distinguished by its ten stamens, and one-celled capsule opening with five valves, which bend inwards so as almost to make the capsule five-celled. *D. lusitanicum*, the only species, a native of the sandy hills of Portugal, grows about one foot high, bearing narrow leaves thickly set with stalked glands, and having large sulphur-coloured flowers. [C. A. J.]

**DROUILLIER (Fr.)** *Pyrus Aria*.

**DRUMMONDIA.** A name formerly given to a group of N. American herbs of the saxifragaceous order, now more commonly regarded as a section of *Mitellaopsis*, and known by their stamens being opposite the pinnatifid petals, and by the bilobed condition of their stigmas. [T. M.]

**DRUMMONDITA.** A genus of one species, *D. ericoides*, a heath-like Rutaceous yellow-flowered undershrub, native of West Australia. It may be known by its stamens, which are combined into a long hairy tube of a purple colour. Of the ten stamens which form this tube, five are fertile, and five sterile, the latter being feathery. Ovaries five, placed on a five-lobed fleshy disk; style thread-like, protruding; stigma button-like. [M. T. M.]

**DRUMSTICK TREE.** *Cathartocaryus conspicua*.

**DRUPACEÆ.** (*Drupiferae*, *Amygdaleae*, *Almondworts*.) According to Lindley this is a distinct natural order, while other botanists regard it as a suborder of *Rosaceæ*. The order belongs to the class of dicotyledons, and the sub class *Calycifloræ Polypetalæ*, and to Lindley's rosal alliance. Trees and shrubs with simple alternate stipulate leaves. Flowers white or pink, in umbels or single; calyx five-toothed, lined with a disk, the fifth lobe superior or next the axis. Petals five, perigynous. Stamens about twenty, arising from the throat of the calyx. Ovary superior, one-celled; ovules two, suspended. Fruit a drupe, with a hard endocarp; seed usually solitary; no albumen. The plants are found in cold and temperate climates of the northern hemisphere. The leaves, flowers and seeds yield hydrocyanic or prussic acid. The bark is astringent, and yields gum. The fruit is in many cases edible. *Amygdalus communis*, the almond-tree, a native of Asia and Barbary, is cultivated in the South of Europe. There are two varieties, one producing sweet, the other bitter almonds. The kernels of the former contain a fixed oil and emulsin, while those of the latter contain also amygdalin, which by combination with emulsin produces prussic acid. *Cerasus communis* yields the common cherry. *C. Lauro-cerasus*, the cherry-laurel or bay-laurel, yields a hydrocyanated oil. The kernels of species of *Cerasus* impart flavour to noyseau, ratafia, cherry-brandy, and maraschino. *Prunus communis* furnishes the common plum, and *P. Armeniaca*, the apricot. *Amygdalus persica* supplies the peach, and a variety gives the nectarine. There are five known genera, and 110 species. [J. H. B.]

**DRUPARIA.** An imperfectly known Brazilian herbaceous plant of the gourd family, with a furrowed stem, and branching tendrils; female flowers in clusters. The fruit is four-celled, four-seeded. [M. T. M.]

**DRUPE (adj.) DRUPACEOUS.** A fleshy or succulent fruit, with a bony putamen or lining, as a plum, — **SPURIOUS.** Any fleshy body inclosing a stone.

**DRUPEOLE.** A little drupe.

**DRYADANTHE.** A genus of the rose family, nearly allied to *Sibbaldia*, but differing in the parts of the flower being arranged in fours. *D. Bungeana*, the only known species, is a little Alpine plant from two to four inches high, found in

the Altai mountains; it grows in dense tufts, and all its parts are covered with silky hairs; the leaves are about a quarter of an inch long, and made up of three leaflets, the central one with three, the lateral ones with two teeth. The stems are terminated by one or two little flowers, each with a four-parted calyx border, four petals, and four stamens, or in the females a like number of ovaries. [A. A. B.]

**DRYANDRA.** A large proteaceous genus, named after Dr. Jonas Dryander, a celebrated botanist, who was librarian to Sir Joseph Banks. It is distinguished by having four-parted apetalous flowers, generally clothed on the exterior with reddish-brown wool; four linear nearly sessile anthers, inserted on the concave extremities of the segments of the flower, bursting longitudinally; a round occasionally furrowed style, slightly exerted, and a cylindrical or clavate stigma. The fruit is a woody follicle. The flowers grow in sessile terminal heads, with a closely imbricated involucre, clothed with dense reddish-brown wool, the outer bracts elliptical, acuminate, the inner ones subulate with a pencil of rufous wool at the point.

*Dryandra*, like its congener *Banksia*, is more remarkable for the variety and peculiar forms of its generally rigid foliage than for the beauty of its flowers. The leaves are either linear or oblong, and with very few exceptions coarsely serrated, lobed or pinnatifid (in *D. speciosa* they are entire), varying considerably in size, some being from a foot to a foot and a half in length, and not more than a third of an inch in breadth, as *D. longifolia*, *D. Brownii*, *D. tenuifolia*, &c.; whilst in others, as *D. præmorsa*, *D. cuneata*, *D. floribunda*, &c., they are only two inches long, and half an inch broad. The genus has only been found on the south and south-west parts of Australia, the larger number of the species having been discovered in the immediate vicinity of King George's Sound and Swan River. [R. H.]

**DRYAS.** A genus of herbaceous plants with shrubby stems, giving name to the sub-order *Dryades* of the *Rosaceæ*. The species are elegant little evergreen plants of humble growth, with rather large simple leaves which lie prostrate on the ground, and showy white or yellow flowers like the *Potentillas* and *Geums*, but well distinguished from both by having the seed-vessels furnished with a long unjointed feathery appendage or tail. They are found either in high latitudes, or in Alpine or sub-Alpine regions, in both hemispheres. *D. octopetala*, the only British species, well marked by its eight white petals, is not unfrequent in the mountainous parts of England, Ireland, and Scotland, the last especially. French, *Dryade*; German, *Silberrosen*. [C. A. J.]

**DRYMARIA.** A genus of *Illecebraceæ* allied to *Spergula*, and like it rather to be referred to a section of *Caryophyllaceæ*. It

consists of tropical or sub-tropical herbs with slender diffuse stems often rooting at the joints, opposite leaves varying from subrotund to linear, often with small caducous stipules, and white flowers in paniculate or corymbose cymes. [J. T. S.]

**DRYMODA picta.** The name of a curious minute epiphytal orchid, with pseudobulbs, and apparently no leaves, found growing in Birmah, and described and figured by Dr. Lindley in the *Sertum Orchidaceum*, t. 8. The flower is single, on the end of a short scape, and inverted, that is the labellum is uppermost. 'The column with its two long petal-like arms is undermost, and the long foot of the column stands over it, bearing at the apex a pair of pink and white lateral sepals, between which hangs down the deep red, fleshy, and hairy labellum.' The other parts of the flower are yellow with brown spots. The four pollen masses without caudicles, attached to a large globose fleshy stigmatic gland, make this plant a link between *Epidendrea* and *Vandea*. [A. A. B.]

**DRYMOGLOSSUM.** A genus of small creeping polypodiaceous ferns, with simple fronds, belonging to the group *Tenitideæ*. The fronds are either of two forms, the fertile ones more or less revolute or contracted, or else the fertile apex of the frond is contracted. The sori form thickish lines at or near the margin on the lower surface. The veins are reticulated, and very frequently obscure; they are, however, uniform, and form roundish or oblong-hexagonal areoles, which enclose a few free veinlets. The species are not very numerous, but are widely scattered, occurring in India, China, and Japan, extending to Norfolk Island, and again occurring in the West Indies. The lines of sori, which are not covered, are sometimes placed directly on the surface of the frond, sometimes sunk in a little groove or channel. In some species the sterile fronds are nearly round; in others they are subcordate, or elliptic, or spatulate, while the fertile are twice their length, and of a linear or linear-oblong outline. The common typical species is *D. piloselloides*, a wide-spread eastern plant. [T. M.]

**DRYMONIA.** A genus of South American shrubs, belonging to the *Gesneraceæ*. They are twiners upon trees in moist places, throwing out rootlets from any part of the stem, and they have opposite serrated petiolate leaves, and large flowers on solitary axillary peduncles, the corolla being campanulate-ringed, gibbous at the base on the posterior side, and with the upper lip two-lobed and the lower three-lobed. The four inclosed didynamous stamens are inserted at the base of the corolla tube, without any trace of a fifth. Seven species have been described. [W. G.]

**DRYOPHILA.** A genus of *Liliaceæ* from Tasmania, consisting of herbs with erect stems leafless below, but with two-ranked narrowly-lanceolate sessile acute

leaves above, and axillary and terminal one-flowered peduncles, supporting white flowers with six spreading segments. The fruit is a pendulous blue sub-globose three-lobed berry. [J. T. S.]

**DRYMYRHIZÆ.** A synonyme of *Zingiberaceæ*, under which the characters of the plants are given. [J. H. B.]

**DRYNARIA.** A genus of polypodiaceous ferns, generally distinguishable by the production of two separate kinds of fronds: the one pinnate or pinnatifid in the usual way, and bearing sori; the other very short, always sterile, coarsely veined, and soon acquiring a harsh dried appearance, quite stalkless, and lobed at the edge so as to resemble the leaf of an oak, whence they are called querciform. The fronds have a very compound venation, two or three series of irregular quadrate areoles being formed within each other, and free veinlets being produced in the ultimate areoles. The fructification is that of *Polypodium*. The genus, which is very well marked, is therefore known by its polypodioid fructification, its compoundly anastomosing venation, and its dwarfed querciform sterile fronds. The segments or pinnae of the larger fronds readily fall away, being articulated at their base. In *D. quercifolia*, which is the type of the genus, the sterile oak-leaf fronds are four to six inches long, and the larger fertile ones from one to two feet or more in length, dark shining green, with long segments bearing a row of sori on each side of their costa. The few species now retained in the genus are all eastern, being found in India, and in the islands of the Pacific, extending as far as Australia and the Feejee Islands. In one species, *D. coronans*, the two forms of frond become combined in one, the fronds of this species being sessile and querciform at the base, but elongated upwards so as to bear the fertile segments on the upper part. Though normally and usually round, as in *Polypodium*, the sori in *D. coronans* sometimes become confluent in lines between the primary veins, and in that state are very similar to those of *Selliguea*. [T. M.]

**DRYOBALANOPS.** A tree, native of the island of Sumatra, yielding a kind of camphor. It constitutes a genus of *Dipteraceæ*, characterised by the calyx having a cup-shaped tube, and a limb divided into five leafy erect segments. The fruit is a capsule, enclosed within the cup of the calyx, and bursting when ripe by three valves: according to Professor Oudemans, of Rotterdam, the most recent investigator of this plant, and who has enjoyed better opportunities for so doing than his predecessors. It appears from his description in the *Annales des Sciences Nat.* (4 ser. v. 100), that the valves of the fruit, in separating from each other, carry with them the investment of the seed, so that the embryo is left exposed in the cavity of the fruit. The fruit is usually described as containing but one seed, but this is not

always the case, as in some instances two seeds have been found. Standing up in the centre of the fruit is a little stalk or columella, which is concealed in a furrow of the seed, where it divides into two wings concealed beneath the edges of one of the cotyledons, which is considerably larger than the other. The seeds have been observed to germinate in the ripe fruit after the dehiscence of its valves.

*D. aromatica* or *D. Camphora* furnishes a liquid called camphor oil, and a crystalline solid known as Borneo or Sumatra Camphor. Camphor oil, which is obtained by incising the tree, has a fragrant aromatic odour, and has been employed to scent soap. The solid camphor is found in the cracks of the wood, and is obtained by cutting down the tree, dividing it into blocks and small pieces, from the interstices of which the camphor is extracted. It is rarely seen in this country, but fetches a very high price. It differs from ordinary camphor by its six-sided crystals, and its greater hardness and brittleness. It does not so readily become condensed on the sides of the bottle wherein it is kept, as ordinary camphor does. This camphor is much sought after by the Chinese, who attribute many virtues to it. It seems to have been long known, as it is mentioned by Marco Polo in the thirteenth century, and Camoens, in 1571, also mentions it as 'the balsam of disease.' [M. T. M.]

**DRYOMENIS.** A curious and somewhat anomalous genus of ferns belonging to the group having naked sori, and having the sori small and oblong, but arranged transversely to the veins and parallel with the costa, thus indicating a technical relationship with *Meniscium*. It has a compound form of venation, the pinnate veins being first united by transverse venules, and then again once or twice united by zigzag veins forming irregular areoles, from which in the sterile fronds free included veinlets branch out. The receptacles are seated on the transverse veins, which join the primary veins proceeding from the costa, so that the sori are placed parallel to the costa. The only species, *D. meniscicarpon* of the Philippine Islands, is a rather coarse-growing fern with broad fronds, becoming taller and contracted with a less copious venation when fertile. It is sometimes associated with the *Polypodies*. [T. M.]

**DRYOPTERIS.** A name originally given by Adanson to the common male fern now called *Lastrea*, and subsequently also applied to a group agreeing with this in general structure. It has not, however, been generally adopted, the name *Lastrea* being preferred by some, who separate the free and netted veined species, and that of *Nephrodium* by others, who, irrespective of venation, combine in one group all the aspidioid plants with reniform fructification. It has been applied by some writers to a section of *Polypodium*. [T. M.]

**DRYOSTACHYUM.** A small genus of

ferns, remarkable for the diversity of the different parts of its fronds. The species are generally referred to the *Polypodiaceæ* group of true ferns, but on account of the sori being seated on a broad receptacle, consisting not of a point on one vein, but of a crowded network of fine veinlets or little veins, they have been sometimes placed along with *Platyserium*, in a small group called *Platyseriaceæ*, in which the same feature occurs. The fronds are leathery in texture, with prominent veins, merely pinnatifid, with the parts broad at the base, but in the upper part deeply divided into narrow or contracted segments, which are fertile. The parts are all articulated so as to separate spontaneously from the rachis or rachis. The sori are large and generally quadrangular, closely set along each side of the costa, each of them covering or seated on a fine network of veins. They are without indusia. The venation is very compound, the veins and venules in the sterile parts anastomosing freely in almost equal-sided areoles, and enclosing free veinlets in the ultimate spaces. There are only two species known, both of which are natives of the Philippine Islands.

[T. M.]

**DRYPETES.** A genus of *Euphorbiaceæ*, comprising a few West Indian and South American trees or shrubs, which have alternate oval or elliptical pointed leathery leaves, and inconspicuous flowers arranged in axillary fascicles, the males and females on different plants. The males have a calyx of four to six divisions, no petals, and two to six free stamens; the females have an ovary of one or two cells seated in a fleshy disk. The fruit is a hard elliptical dry drupe. The genus is nearly allied to *Hemicycella*, but the latter has numerous stamens.

[A. A. B.]

**DRYPIS.** A genus of *Caryophyllaceæ*, distinguished by having a one-seeded utricular capsule, which breaks across transversely. *D. spinosa*, a Mediterranean herb, has branched rigid fragile stems, with opposite subulate leaves ending in spines, and small rose-coloured flowers in dense corymbose cymes, with only five stamens in each.

[J. T. S.]

**DRY ROT.** We are concerned with this subject only so far as it may be the effect of *Fungi*, or as calling those *Fungi* into especial notice. As, however, Dry Rot may be the effect of slow chemical combustion as well as of *Fungi*, and the results are much the same in either case, it is well that any mycologist who may attempt the investigation of the subject should be aware of the fact.

Dry Rot may be produced by various species, as *Polyporus hybricus*, *Thelephora putans*, *Merulius lacrymans*, &c. In oak it is generally due to the first, and in the wood of conifers to the last. Different kinds of timber, moreover, in tropical countries have their own enemies, but these at present have not been sufficiently investigated. The spores of the *Fungi*

may be brought into the dock-yard with the wood, in which case they are mostly the result of some ancient malady, and may have remained dormant in the wood altogether, or may have existed in the shape of minute spawn. The fox oak, which is grown on old stools, owes its colour to incipient decomposition accompanied by delicate spawn, and when exposed to circumstances favourable to fungal development, the perfect form of the fungus by which it was injured will soon make its appearance. Elm trees are often strongly impregnated with spawn before they are felled, and we have lately seen *Polyporus umarius* bursting forth from the cut surface of an elm tree which fell a sacrifice to the spring gales of 1860, the whole wood being evidently affected.

When the fungus attacks the surface, it soon runs over it, and its spawn penetrates the wood, destroying all before it. The best remedy against Dry Rot consists in careful selection of wood, perfect ventilation, and patient seasoning, added to the employment of such kinds of wood for particular purposes as may be most suitable to the situation they are intended to occupy. Mineral salts may also be employed, but the remedy on which authorities in the present day insist the most is creosote, which has the property of coagulating albumen, and making it enter into combinations unfit for vegetation. It is, however, found that where the proper conditions have been secured, it is quite as economical to do nothing, for even with bad materials Dry Rot is not universal, and with good, attended by proper precautions, there will be little or no Dry Rot except under accidental circumstances which are favourable to its progress. In damp situations with imperfect ventilation, even should no fungus be present, decomposition is sure to take place, destructive to the wood, and prejudicial to the health of those who are constantly in its neighbourhood. In cellars and domestic buildings where the fungus has not already committed too much mischief, it may be effectually checked by washing it with a strong solution of corrosive sublimate. Where fungus does not exist, the remedy is scarcely applicable when decay has commenced, though it may be useful in the first instance.

[M. J. B.]

**DUBOISIA.** A name applied to an Australian shrub, placed by Miers in *Atropaceæ*, but by others referred to *Scrophulariaceæ*. Its flowers are in axillary clusters, white, with a two-lipped calyx; corolla funnel-shaped, the limb five-parted; stamens five, included within the corolla, four fertile (two long, two short), and one rudimentary; ovary with two many-ovuled compartments; fruit berry-like.

[M. T. M.]

**DUBYEA.** A genus of *Compositæ*, nearly related to *Hieracium*, but differing in having beaked achenes. Of the three known species, one with the habit of a sowthistle is found in Australia; another,

somewhat like a dandelion, is found in Armenia; and a third, like a hawkweed, grows in the Himalayas from Sikkim westward to Kumaon, at elevations between 8,000 and 12,000 feet. Its upper leaves are hairy, oblong, entire or toothed, and embracing the stem, while the lower are nearly triangular, and narrowed into a winged stalk. The yellow flower-heads have their lance-shaped involuclral scales beset with black hairs, and the compressed striated achenes are narrowed into a beak, and crowned with a pappus of numerous rough hairs. The genus bears the name of M. Duby, a French botanist. [A. A. B.]

**DUC DE TOLE.** (Fr.) *Tulipa suaveolens*.

**DUCHARTREA.** A genus of *Gesneraceae*, containing a single species, a native of the mountains of Cuba. It is an erect branching shrub, wrinkled with resinous warts, and having coriaceous toothed leaves and greenish flowers in few-flowered corymbs. The corolla campanulate, slightly constricted on the underside, and the limb cut into five unequal roundish lobes, furnished with awned teeth around the margins; the stamens are didynamous with a sterile fifth. The base of the style is surrounded by an erect pentagonal cup. The warty oval fruit is crowned by the persistent calyx. [W. C.]

**DUCHASSAINGIA.** *Erythrina*.

**DUCHESNEA.** The name sometimes applied to an East Indian strawberry, *Fragaria indica*, with insipid fruit and yellow flowers. [A. A. B.]

**DUCK'S-FOOT.** *Podophyllum*.

**DUCKMEAT** or **DUCKWEED.** The common names of the curious floating aquatic, which form the genus *Lemna*.

**DUCTS.** Tubular vessels marked by transverse lines or dots: apparently in some cases modifications of spiral vessels, when they are called *closed*, *annular*, *reticulated*, and *scalariform*; sometimes analogous to pitted tissue, when they are called *dotted*, and form *bothrenchyma*.

**DUCU.** The resin of *Clusia Ducu*.

**DUDAİM.** A biblical plant, regarded as the Mandrake, *Mandragora officinalis*.

**DUFOUREA.** A genus of *Convolvulaceae*, containing five species of South American twining undershrubs with alternate entire leaves, and numerous white flowers in panicles on axillary or terminal peduncles. The calyx consists of five sepals, the two outer of which are membranaceous, and coloured, very large, almost hiding the funnel-shaped corolla, within which are five included stamens, with short subulate filaments. The two-celled ovary is surmounted by two styles or a single one deeply-cleft, with capitate stigmas. [W. C.]

**DUFRESNEA.** A Persian annual of the order *Valerianaceae*. The leaves are entire; the flowers in close cymes, sometimes uni-

sexual; the calyx limb has three unequal ovate acute notched segments, which increase in size as the fruit ripens; the corolla is tubular, regular, spurious, its limb five-lobed; stamens three. The fruit is membranous, very hairy, crowned by the calyx lobes, three-celled, with two of the cells empty and distended. [M. T. M.]

**DUGUETIA.** A genus of *Anonaceae*, consisting of Brazilian trees with scurfy branches. The flower is not described, but the receptacle bearing the fruits is divided transversely into two sections, the lower globular, woody, marked with the scars of the fallen stamens, the upper portion somewhat conical, spongy, pitted; the carpels inserted on this receptacle are numerous, ovate, angular, terminated by the persistent styles, woody and one-seeded. *D. guianensis* is said to furnish the light elastic lance-wood of Cuba and Guiana, used by coachbuilders principally. [M. T. M.]

**DUK.** The horsehair-like fibres of the Gomuti palm, *Saguerus saccharifer*.

**DULCIS.** Any taste which is not acrid.

**DULCAMARA.** *Solanum Dulcamara*, the Woody Nightshade or Bittersweet.

**DULSE.** A name given in Scotland to several different kinds of rose-spired *Algae*, but especially to *Rhodymenia palmata* and *Iridora edulis*, which are extensively eaten on the sea-coasts, and which occasionally make their appearance in the market. We have ourselves been thankful for this coarse and parchment-like food amongst the Western Isles, when it was impossible to procure any other kind of sustenance. *Laurencia pinnatifida* affords an inferior Dulse, known under the name of Pepper Dulse. These species are generally eaten raw. When cooked they have an unmistakable sea-twang, which, in spite of all the pains of Soyer, forbids their entrance into any acceptable food, where more sapid articles are procurable. [M. J. B.]

**DUMERILIA.** A genus of perennial Mexican herbs, belonging to the lip-flowered group of *Compositae*. They are smooth plants from one to three feet high, with sessile oval rigid leaves, which embrace the stem by their base, and shortly-stalked flower heads disposed in terminal corymbs; each capitule is about half an inch long, and contains from five to fifteen white florets, enclosed by an involucre of about three series of lance-shaped scales. The achenes are slightly beaked, dilated at the apex, and crowned by a pappus of one series of numerous white pilose bristles. In the nearly-allied *Perezia*, the hairs of the pappus are in two series; but according to Dr. A. Gray, this character is here of little importance, and he would unite the genus to *Perezia* along with *Clarionea* and *Homolanthus*. The roots of the two known species are stringy, and the stem at the base is furnished with a tuft of rusty hairs. From the roots of *D. Aman*, a curious chemical production known as Pipitzahuac is prepared; it resem-

bles flakes of gold, and is said to be powerfully drastic, with an odour of valerian, and useful as a dye. The plant is also known as *Peresia fruticosa* and sometimes *Acourtia rigida*. [A. A. B.]

**DUMUS** (adj. DUMOSE). A low branching shrub.

**DUNBARIA**. A small genus of twining plants of the *Pes* family, natives principally of Tropical Asia, and represented in Australia by one species. In foliage and habit they are somewhat like *Phaseolus*, but the leaves are smaller. The large flowers are generally bright-yellow, and disposed in loose axillary racemes. The calyx is four-cleft to the middle; the corolla remarkable for the large membranous standard, much longer than the calyx, which embraces and hides the other petals, and has two callosities at its base. In some species it is an inch long. The pod is flattened and hairy, strongly compressed between the seeds. The genus is nearly related to *Cylata*, which, however, has a large membranous calyx completely hiding the corolla. It is named in honour of Prof. Dunbar of Edinburgh. [A. A. B.]

**DUNGAN**. *Myristica spuria*.

**DUODENI**. Growing twelve together.

**DUPERREYA**. A New Holland Convolv. Jaccous plant, now united with *Porana*—a twining undershrub, with petiolate narrow leaves, and solitary axillary flowers at the ends of the branches, having a somewhat funnel-shaped corolla. The capsule contains a single seed. [W. C.]

**DUPLICATE**. Growing in pairs. In composition the word indicates the repetition of a character: thus *duplicate-crenate* is when each crenel is itself crenate; *duplicate-dentate*, when each toothing is itself toothed; *duplicate-pinnate*, when the leaflets of a pinnate leaf become themselves pinnate; *duplicate-serrate*, when each serrature is itself serrated; and so on.

**DUPLO**. Twice as much as, or twice as many as.

**DUPONTIA**. A genus of grasses belonging to the tribe *Aveneæ*, distinguished by the inflorescence being in contracted panicles; spikelets ovate, two-flowered, with the rudiment of a third foret; stamens three; ovary smooth; styles two, feathery. The species are from the extreme northern limits of phænogamous vegetation: *D. Fischeri* from Melville Island, and *D. pillosa* from Russian North America. [D. M.]

**DUPUISIA**. A genus of *Anticardiaceæ*, consisting of trees natives of Senegal. The calyx is cup-shaped, persistent, slightly five-toothed; petals five; stamens five, inserted with the petals into the calyx; ovary one-celled, one-seeded. Now united with *Saccolata*. [M. T. M.]

**DURAMEN**. The heart-wood, or that part of the timber of a tree which becomes hardened by matter deposited in it. It is

next the centre in Exogens, and next the circumference in Endogens.

**DURANTA**. A genus of S. American bushes of the vervain family, easily distinguished by the racemed flowers, and by the nature of the fruits, which are composed of four nuts enclosed in the calyx tube, which is contracted at top; they are hard and about the size of a pea, each nut with two one-seeded cells. Some are spiny, others unarmed; but all are straggling bushes with four-angled grey twigs, and opposite or whorled stalked leaves, in some like those of the privet, in others toothed. The pretty blue flowers are borne in great profusion in racemes towards the ends of the branches, each about half an inch long, and having a tubular five-ribbed five-toothed calyx, and a corolla about three times the length of the calyx, with a flat border of five unequal rounded lobes, nearly half an inch across. Some of them are said to be poisonous, and the seeds are not eaten by birds. *D. Plumieri* is in cultivation, and may often be seen in plant-stoves. About six species are known. [A. A. B.]

**DURELIN**. (Fr.) *Quercus sessiliflora*.

**DURIEA**. A genus of *Etiaceæ*.

**DURIAN**. *Durio zibethinus*.

**DURIO**. The tree producing the celebrated Durian fruit of the Indian Archipelago, *D. zibethinus*, is the only species of this genus of *Sterculiaceæ*. It forms a large forest tree, attaining sixty or eighty feet in height, with somewhat the general appearance of an elm. The leaves are entire, oblong, rounded at the base and taper-

Durio zibethinus.

ing upwards into a long point, densely covered beneath with minute scales, which give them a silvery red appearance. The flowers are yellowish-green, produced in little clusters upon the trunk or main branches, each flower having two large concave bracts at its base; the calyx is tubular and five-toothed; the corolla has five petals, which are partly joined so as to form a short tube; the stamens are numerous collected into five bundles, and have twisted or uneven anthers; and the

scaly ovary is surmounted by a long thread-like style, and a simple round stigma. The fruit varies in shape, being either globular or oval, and measures as much as ten inches in length; it has a thick hard rind, entirely covered with very strong sharp prickles, and is divided into five cells, each of which contains from one to four seeds rather larger than pigeons' eggs, and completely enveloped in a firm luscious-looking cream-coloured pulp, which is the eatable portion of the fruit.

This tree is very commonly cultivated throughout the Malayan Peninsula and Islands, where its fruit, during the period it is in season, forms the greatest part of the food of the natives. Considerable diversity of opinion exists among epicures as to the relative merits of several well-known tropical fruits, including the Durian, the mangosteen, the cherimoyer, and the pineapple, any one of which is made to occupy the foremost place, according to individual taste. The flavour of the Durian, however, is said to be perfectly unique; and it is also quite certain that no other fruit, either of tropical or temperate climes, combines in itself such a delicious flavour with such an abominably offensive odour—an odour commonly compared either with putrid animal matter, or with rotten onions. It might be supposed that a fruit possessing such an odour could never become a favourite; but it is said that when once the repugnance has been overcome, the Durian is sure to find favour, and that Europeans invariably become extremely fond of it. Mr. A. Wallace observes that 'a rich custard highly flavoured with almonds gives the best general idea of it, but there are occasional wafts of flavour that call to mind cream-cheese, onion-sauce, sherry wine, and other incongruous dishes. Then there is a rich glutinous smoothness in the pulp which nothing else possesses, but which adds to its delicacy. It is neither acid, nor sweet, nor juicy; yet it wants none of these qualities, for it is in itself perfect. It produces no nausea or other bad effect, and the more you eat of it the less you feel inclined to stop. In fact, to eat Durians is a new sensation worth a voyage to the East to experience.' The unripe Durians are cooked as a vegetable, and the pulp of the ripe fruit is salted and preserved in jars; while the seeds are roasted and eaten like chestnuts. [A. S.]

**DURMAST.** *Quercus sessiliflora pubescens*.

**DURRA.** *Sorghum vulgare*.

**DUST BRAND.** *Ustilago*.

**DUTCHMAN'S BREECHES.** *Dicentra Cucullaria*.

**DUTCHMAN'S LAUDANUM.** A tincture of *Passeflora rubra*, or, according to some, of *Murucuja ocellata*.

**DUTCHMAN'S PIPE.** An American name for *Aristolochia Sipho*.

**DUTTONIA.** A name originally pro-

posed by Dr. Mueller for an Australian composite plant, which proved to be the same as *Dimorpholepis*; and afterwards applied by him to a myoporaceous shrub from South Australia, which he published as a new genus, but which he has more recently reduced to *Eremophila*.

**DUVALIA.** A name given by Haworth to some species of *Stapelia*.

**DUVAUA.** A genus of *Anacardiaceae*, consisting of trees or shrubs, natives of extratropical South America. They are sometimes armed with axillary spines; the leaves are entire; the flowers are in clusters, each with a four or five-cleft persistent calyx; four to five petals inserted beneath an eight-lobed disk; eight to ten stamens, those alternate with the petals longer than the others; and a sessile one-celled ovary. The drupe is pea-shaped, having the smell of juniper. Some of the species are grown as evergreen wall shrubs, with white or greenish flowers. Dr. Lindley remarks 'that the leaves of *D. lasifolia* expel their resin with such violence, when immersed in water, as to have the appearance of spontaneous motion in consequence of the recoil.' [M. T. M.]

**DWALE.** The Deadly Nightshade, *Atropa Belladonna*.

**DYCKIA.** Brazilian herbs, named in honour of Prince Salm-Dyck, an amateur and patron of science. They constitute a genus of *Bromeliaceae*, having lance-shaped pointed leaves, and bearing flowers in panicles, with spiny bracts. The perianth is six-parted, the three outer segments calycine, the three inner ones petal-like, bell-shaped, rather fleshy; the six filaments of the stamens are united below into a tube adherent to the inner segments of the perianth; the ovary is free, three-lobed, with three spreading forked stigmas. *D. variiflora* is a very showy plant with orange-coloured flowers. [M. T. M.]

**DYER'S-WEED.** *Reseda Luteola*; also *Genista tinctoria*, and *Isatis tinctoria*.

**DYNAMIS.** A power. A figurative term employed by Linnaeus to express the degrees of development of stamens. Thus his *Didynamis* signified stamens of two different lengths, or of two different degrees of development.

**DYSOPHYLLA.** A genus belonging to the labiate order, distinguished from its congeners by the corolla having a short tube, the border divided into four nearly equal pieces, the upper division entire or slightly notched. The few species belonging to it are herbs, natives of India and Java; the leaves opposite or in whorls; the flowers in more or less dense clusters. The name is derived from Greek words signifying 'fetid leaf,' and descriptive of the odour of the plants, in which property they differ from most of the species of the same order. [G. D.]

**DYSOXYLON.** Large Javanese trees forming a genus of *Meliaceae*, with com-

pound leaves, whose leaflets are oblique at the base; the flowers are in axillary panicles with four or five-parted whorls; the tube, formed by the union of the stamens, is eight to ten-toothed with as many anthers in the interior; ovary three or four-celled surrounded at the base by a small disk; capsule three-celled, the seeds solitary in each compartment. [M. T. M.]

**DYSSOCHROMA.** A climbing Brazilian solanaceous shrub. It has a calyx of five persistent segments; a fleshy funnel-shaped corolla with the limb divided into five acute revolute segments; five protruding stamens, the anthers opening longitudinally, and surmounted by a small point; an erect style thickened at the top; and a two-celled ovary placed on a large fleshy disk. [M. T. M.]

**DYSSODIA.** A genus of composite herbs, nearly related to *Tugetes*, but differing in the nature of the pappus, which is composed of a number of chaffy scales pinnately or palmately divided above, and entire below, so that they appear like a polyadelphous pappus. Of the eight known species, two are found in the United States and the others in Mexico. Some have linear or lance-shaped entire or toothed leaves; in others they are pinnatisect. The yellow flower-heads are disposed in loose corymbs, or panicles at the ends of the branches, and have an involucre of one series of scales, more or less united by their edges, and often indented by an outer series of bracts. The florets are all tubular and perfect, but in most of them the outer ones are strap-shaped and contain a pistil only. Most of these herbs emit an unpleasant odour from the presence of oily matter secreted by the glandular dots of the leaves. *D. chrysanthemoides*, a dwarf annual with pinnatisect leaves, grows in great profusion over the western prairies of Illinois; and in autumn exhales so unpleasant an odour as to sicken travellers. [A. A. B.]

**E, EX.** In composition = without; thus ex-aluminous signifies without alumen.

**EAGLE-WOOD.** The timber of *Aloxylin Agallochum*; and also of *Aquilaria obovata*, and *A. Agallocha*.

**EARINHAU.** *Ascarina polystachya*.

**EARCOCKLE.** The name of a curious disease in wheat, in which the grain becomes blackened and contracted, and mealy within from the myriads of worms belonging to the genus *Vibrio*. The little animals are extremely tenacious of life, and though apparently reduced to dust, when steeped in warm water for a short time, after being dry for many months, they recover their former activity. The disease not only impairs the value of the wheat, but the little worms are very annoying to the miller from filling up the pores of his bolting-cloths. The affection is local, and quite unknown in many parts of England. In some districts it is called **Purple**. [M. J. B.]

**EARED.** The same as *Auriculato*.

**EARTH-GALL.** *Ophiorrhiza Mungos*.

**EARTH-NUT.** *Arachis hypogaea*.

**EARTH-STAR.** *Geaster*.

**EARTH-TONGUE.** *Geoglossum*.

**EAU D'ANGE.** A perfume distilled from the flowers of *Myrtus communis*. — **DE COLOGNE.** A well-known alcoholic perfume, to which *Lavandula vera* and *Rosmarinus officinalis* contribute their fragrance. — **DE CRE'OLE.** A stomachic distilled from the Mammee apple, *Mammea americana*. — **DE MANTES.** A liqueur distilled from *Croton balsamiferum*. — **MEDICINALE.** A gout medicine prepared from *Gratiola officinalis*. — **D'OR.** A liquid distilled from *Conrallaria majalis*. — **D'ORME.** A liquid secreted in certain galls of the elm.

**EBENACEÆ (Ebenads).** A natural order of corollifloral dicotyledons, belonging to Lindley's gentianal alliance. Trees or shrubs, not milky, with alternate exstipulate leathery and entire leaves; flowers hermaphrodite, or staminate and pistillate; calyx three to seven-cleft, persistent; corolla three to seven-cleft; stamens usually twice or quadruple the number of the corolline segments. Ovary three or several-celled, with one or two pendulous ovules in each cell. Fruit a round or oval berry; seeds albuminous. [They are chiefly Indian; one species is naturalised in South Europe, and is indigenous to N. Asia, and China. They are also represented in Tropical Africa, at the Cape, in South America, Brazil, and Australia.] The trees of this order yield hard and durable timber. The bark of some is astringent, and the fruit is sometimes eatable. The heartwood of different species of *Diospyros* constitute the ebony of commerce, of which there are many varieties, e. g. *D. reticulata*, Mauritius Ebony; *D. Melanoxylon* and *D. Ebenaster*, East Indian Ebony; and *D. Ebenum*, Ceylon Ebony. *Diospyros guianensis* yields the variegated Calamander wood of Ceylon and the coasts of India, which is shipped from Bombay and Madras. The Ker fig of Japan is the edible fruit of *Diospyros Eaki*; while the Persimmon is the fruit of *D. virginiana*. [Five genera only are recognised in Mr. Hieron's recent monograph (*Rosena, Euclea, Diospyros, Maba, Tetractis*), with about 25 species.] [J. H. B.]

**EBÉNIER. (Fr.)** *Diospyros Ebenum*.

**EBENUS.** A genus of the pea family, numbering about eight species, closely related to *Onobrychis*, but the pods smaller, and not toothed or crested. They are elegant little shrubs or biennial plants, chiefly confined to the high mountainous regions of Eastern Europe and Asia Minor, though *E. pinnata* is found in Algeria, and another as far east as Beloochistan. All their parts are commonly crowned with silky hairs; and the leaves are usually unequally-pinnate, made up of three to five pairs of linear or lance-shaped leaflets, though in a few they are digitate or simple. The peduncles are axillary or terminal, and

bear dense spikes or round heads of pink or violet blossoms, in which the deeply-lobed calyx is conspicuous, and densely clothed with silky hairs. The keel of the corolla has the very minute triangular wings adhering to its claw near the base, and of the ten stamens, nine are united into a tube, and one is free. [A. A. B.]

EBERMEYERA. *Adenoma*.

EBOE TREE. *Dipterix eboensis*.

EBONY. The timber of various species of *Diospyros*, especially *D. Ebenum*, *E. nutans*, and *Melanoxylon*. —, AMERICAN. *Brya Ebenus*. —, GREEN. *Ezcararia glandulosa*, and also *Jacaranda coultifolia*. —, JAMAICA, or WEST INDIA. *Brya Ebenus*. —, MOUNTAIN. *Bauhinia variegata*.

EBRACTEATE. Having no bracts.

EBURNEUS. Of the colour of ivory. ?

ECALCARATE. Not having a spur.

ECASTAPHYLLUM. A small genus of leguminous shrubs found in S. America and W. Africa, nearly related to *Dalbergia*, which has long straight thin pods, while these have flat, nearly orbicular one-seeded pods, whose valves have a tendency to a corky thickening. The leaves are sometimes simple, but more generally pinnate, and made up of three to five pairs of oval leaflets, and an odd one. Their little white straw-coloured or reddish-purple pea flowers are disposed in short axillary cymes. The calyx is bell-shaped and five-toothed; the stamens eight or nine, but more usually ten, nine united and one free. *E. Monstaria*, a pinnate-leaved species with white flowers found in America and Africa, has red wood, which is said to furnish a resin like dragon's blood, and the root when cut emits a purple juice. The name is sometimes written *Decastophyllum*. [A. A. B.]

ECBALLIUM. A genus of *Cucurbitaceae* closely allied to *Momordica*, from which it differs in the absence of tendrils, and of rudimentary stamens in the female flowers, and by the peculiarity of the fruit, which when ripe separates from the stalk and expels, with considerable force, the brown seeds through the aperture made by the removal of the stalk. *E. agreste* (*Momordica Elaterium*), the Squirting Cucumber, a native of waste places in the south of Europe, is an annual plant with prostrate branching stems, and heart-shaped rough leaves. The flowerstalks are axillary: the male flowers in clusters with bell-shaped yellow green-veined corollas; the females solitary. The fruit is a small elliptical greenish gourd, covered with soft triangular prickles. These fruits forcibly eject their seeds, together with a mucilaginous juice, a phenomenon said by Dutrochet to be due to endosmosis.

The drug known as *Elaterium* is the dried precipitate that is deposited from the juice which flows from the fruit or rather from the pulp surrounding the seeds. So powerful is pure *elaterium*, that one eighth part of a grain is sufficient to produce

strong cathartic effects: it is, however, rarely obtained pure. It is of great value in certain cases of dropsy and of cerebral disease, where an active remedy is required; but as its action is violent it

*Ecballium agreste*.

requires to be administered with great caution, and in cases where there exists no objection to its use. The active principle of *elaterium* is a crystalline substance called *elaterin*. The plant is grown for medicinal purposes at Mitcham and elsewhere. It is related of Dr. Jackson, who was formerly lecturer on botany at St. George's hospital, that he suffered severely from the effects of this plant, in consequence of having conveyed some specimens of it in his hat from the Jardin des Plantes to his lodgings in Paris. [M. T. M.]

ECHLASTERESIS. The production of buds within flowers, in consequence of monstrous development; or on inflorescences.

ECCREMOCARPUS. Handsome climbing plants with a somewhat shrubby stem, long succulent branches, much-divided leaves, terminating in a branched tendril, and tubular yellow or green flowers, which are divided into five equal lobes. The stamens are four, two longer than the others, with the rudiment of a fifth. The seeds are produced in a one-celled two-valved ovate capsule, and are surrounded by a membranous wing, on which account they are favourite objects for microscopes of low power. The genus belongs to the *Bignoniaceae*. *E. longiflorus* has a red calyx and a very long corolla with a yellow tube and green limb. *E. scabra*, a handsome Chilean species with orange-coloured flowers, much cultivated as an ornamental creeper, is sometimes called *Colampelis scabra*. [O. A. J.]

ECHALOTTE. (Fr.) *Allium ascalonicum*.

ECHARBOT. (Fr.) *Trapa natans*.

ECHEANDIA. A genus of *Liliaceae*, near-

ly related to *Phalangium*, from which it differs in the club-shaped filaments of the stamens being furnished above with short obtuse recurved teeth. The six known species, which extend from Mexico southwards to Brazil, are perennial herbs, with roots consisting of fascicles of fleshy fibres, grassy root leaves six inches to a foot or more in length, and rising from the midst of these a branching flower-stem, six inches to four feet high, with narrow bracts at the forking points, and white or orange-yellow asphodel-like drooping flowers, disposed in racemes, the individual flowers seldom more than half an inch across. *E. terniflora*, a yellow-flowered Mexican species, has been cultivated in English gardens. [A. A. B.]

**BOHEVERIA.** A handsome genus of succulent often fruticose plants belonging to the *Crassulaceae*, and chiefly natives of Mexico. The leaves, which are generally glaucous, and sometimes excessively so, are not uncommonly spatulate in form, sometimes disposed alternately along the stem, sometimes collected into rosulate tufts. The flowers are in racemes or cymes, often secund, and generally of a bright scarlet or yellow colour, and very ornamental; they have a five-parted calyx, a perigynous five-parted corolla, whose erect segments close up into a pitcher-like form, ten included stamens, with short hypogynous scales, and five free one-celled ovaries, which become many-seeded follicular capsules. Many of the species are in cultivation, and they are esteemed as including some of the most interesting and beautiful of greenhouse succulents. *E. secunda* and *glauca* are particularly ornamental dwarf herbaceous species, well adapted for indoor window gardens. [T. M.]

**BCHIALES.** One of Lindley's alliances, which includes the *Boraginaceae*, *Labiata*, &c.

**BOCHINACANTHUS.** A small genus of *Acanthaceae*, containing four species, natives of India. They are herbs with denticulate leaves, and small flowers which grow in secund axillary cymes running into a terminal panicle, and furnished with narrow bracts and no bracteoles. The calyx is deeply five-cleft, the corolla funnel-shaped, the stamens four, included, didynamous, united in pairs at the base of the filaments, and the stigma simple. The round two-celled capsule bears many seeds. [W. O.]

**BOCHINAIIS.** A small genus of *Compositae*, found in Armenia, Siberia, and N. W. India. The leaves and flower-heads are very like those of our own *Carduus arvensis*. The chief characters which separate these plants from *Carduus* are the thin and lacerated apices of the involucreal scales, which end in short spiny points, and the short lacerated tails seen at the base of the outer lobes. [A. A. B.]

**BOCHINARIA.** A genus of grasses belonging to the tribe *Pappophoreae*. The inflorescence is in simple globose spikes;

skelets two to four-flowered, the superior flower stalked; glumes two, membranaceous and keeled, the lowest with two awns at the tip, shorter than the superior one, which has only one awn at the apex; pales or inner glumes two, the lowest five-nerved and cleft at the tip. Of this small genus only two species are described, namely, *E. capitula*, which is a native of Africa as well as Syria, and *E. pumila*, a native of Spain. [D. M.]

**ECHINATE.** Furnished with numerous rigid hairs, or straight prickles; as the fruit of *Castanea vesca*.

**ECHINOCACTUS.** The plants composing this genus of Indian figs, like many others belonging to the same natural order, assume most grotesque forms. The name is derived from two Greek words, *echinos*, a hedgehog, and *kaktos*, a prickly plant, in allusion to many of the species being globular and thickly beset with spines, resembling a rolled-up hedgehog. There are hosts of species enumerated in botanical works, more than half of them natives of Mexico, and the rest distributed throughout South America, extending as far south as Buenos Ayres and Mendoza.

Like the generality of the order, they delight in hot, dry, sandy, or stony places, exposed to the full power of the sun. They consist merely of a fleshy stem, without leaves, and are either of a globular form slightly flattened at the top, or oblong, or cylindrical, and only attain a large size when they are very old. Whatever their shape or size, the stems are always either more or less fluted and ribbed, or covered with tubercular swellings, the number of the ribs varying in the different species, being numerous and sharply defined in some, while in others they are fewer and merge into each other. Nearly all the species are armed with stiff sharp spines, arranged in clusters, and seated upon little woolly cushions placed at intervals along the edges of the ridges, or on the tips of the tubercles. The flowers are generally large and showy, and are produced at or near the top of the plant, growing from the upper side of the younger fascicles of spines; but in some species the top of the plant is densely covered with light brown wool, from out of which the flowers proceed. The calyx has a broad generally short tube, the lower or outermost sepals being of a scale-like character, and the upper ones more like petals, into which, in fact, they gradually pass, the inner petals spreading out and radiating. The numerous stamens are fixed to the inside of the calyx-tube, and are shorter than the petals. The style is columnar, and separates into from five to ten radiating stigmas, which project very slightly beyond the stamens. The fruit is generally scaly or prickly, and is crowned with the withered remains of the flowers.

*E. Visnaga*, which is perhaps the largest of the genus, is a native of San Luis de Potosi, in Mexico. Large plants of this have from forty to fifty sharp ridges, with

the clusters of spines sunk into their edges at short intervals. The aggregate number of these spines upon a single plant is something enormous; a comparatively small plant in Kew Gardens was

*Echinocactus Vianaga.*

estimated to have 17,000, and a larger specimen, at the same place, could not have had less than 51,000. The Mexicans commonly use them for toothpicks, hence the specific name *Vianaga*, which means a toothpick. The flowers are bright yellow. Some years ago a plant of this species, weighing one ton, and measuring nine feet in height by three in diameter, was forwarded to Kew, where, however, it lived only a short time. [A. S.]

**ECHINOCARPUS.** A small genus of *Tillaceæ*, found in India, Java, and Eastern Tropical Australia. They are most nearly related to *Sloanea*, but differ in having petals. All are large trees with alternate stalked oval oblong or lance-shaped leaves. The flowers are arranged in short axillary racemes or fascicles, seldom in terminal panicles; and each is about half an inch in diameter, with a five-parted calyx, five-lacerated petals, numerous stamens with pointed anthers, and a five-celled ovary crowned with a simple style. In some species the fruits are beset with straight prickles, and resemble those of the Spanish chestnut; in others the outer covering of the fruit consists of short crisp closely-packed rigid hairs. In all they are five-celled with five seeds, and split when ripe into five woody portions. This prickly covering of the fruit has suggested the name. [A. A. B.]

**ECHINOEREUS.** A genus of *Cactaceæ*, sometimes combined with *Cereus*, but in the latter the tube of the flowers is very long, while in *Echinocereus* it is always short, besides which the fruit is crowned with the withered remains of the flower, and the seeds are always rough or warted, not smooth, as in true *Cereus*. The species number between twenty and thirty, and are all natives of the hot dry regions of Mexico and Texas. They seldom exceed a foot in height, the stems being simple or branched, and either divided into very numerous ridges, or with only from four to ten, all being formidably armed with

sharp spines. *E. pectinatus* grows about eight inches high, and two inches thick, and has about twenty ridges bearing at short intervals dense clusters of very small yellowish and rose-coloured spines. The fruit, like that of several other species, is of a purplish colour, and very good eating, resembling a gooseberry. The Mexicans, who call the plant *Cabeza del Viego*, eat the fleshy part of the stem as a vegetable first carefully freeing it of the spines. [A. S.]

**ECHINOCHLOA.** A genus of grasses of the tribe *Panicææ*. The species are now generally included under *Panicum*. [D. M.]

**ECHINOCYSTIS.** A North American cucurbitaceous annual with climbing stems, palmate leaves, branching tendrils, and small greenish flowers; the males in clusters, the females in juxtaposition, either solitary or in tufts upon a short stalk. The calyx segments and petals are six in number, the stamens three, in two parcels, with connate wavy anthers. In the female flower there are three abortive stamens. The two-celled fruit is somewhat globular, spiny, at first juicy, but subsequently dry and fibrous. [M. T. M.]

**ECHINOLENA.** A genus of grasses belonging to the tribe *Panicææ*, now included in *Panicum*. [D. M.]

**ECHINOPE DE RUSSIE.** (Fr.) *Echinops sphaerocephalus*.

**ECHINOPHORA.** A genus of umbellifers distinguished by the prickly character of the parts which surround the flowers and fruit. The species are perennial herbs, having generally a rigid habit, and, as the name implies, partly covered with spines. They are chiefly found on the borders of the Mediterranean, and are more of interest owing to their peculiar appearance than on account of any useful or economical property which they possess. *E. tenuifolia*, found on some parts of the Mediterranean shore, is, however, reported as acting moderately upon the kidneys. One species, *E. spinosa*, still holds a place in the British Flora, having been reported as found on the sandy sea-shores of Lancashire and Kent; but it is now extinct. [G. D.]

**ECHINOPOGON.** A small genus of curious grasses belonging to the tribe *Agrostideæ*, having the inflorescence in crowded ovate panicles; stamens three; styles two, with plumose stigmas; fruit oblong-lanceolate, awned. The species are all natives of New Holland. [D. M.]

**ECHINOPS.** A genus of the composite family, numbering upwards of thirty species, many of them known as Globe Thistles. They are remarkable for having the heads one-flowered and arranged in dense round clusters at the ends of the branches, so that each cluster of flower-heads has the appearance of a single head containing many florets. They are found as far eastward as Kumaon in the Himalayas, extend westward to Spain, and appear in

greatest numbers in Asia Minor. Some are annuals, but most of them are biennial or perennial erect simple or branching herbs from two to six feet or more high, furnished with large thistle-like spiny leaves, once, twice, or thrice pinnately-parted, the lower surface usually covered, like the stems, with loose white wool. The flowers are white or pale blue, and the compound heads one to three inches in diameter, surrounded by a common involucre of narrow scales, while each separate single-flowered head has an involucre of numerous scales, the outer hair-like, the inner broader and spiny-pointed. The silky cylindrical achenes are crowned with a pappus of numerous short bristles. *E. strigosus*, an annual species, native of Spain, is said to yield the substance known as Spanish tinder. Three sorts of it are prepared, one from the pubescence of the flower-heads, another from that of the leaves, and a third from that of the stems. [A. A. B.]

**ECHINOPSIS.** A genus of Indian figs, formerly combined with *Echinocactus*, but now separated and placed with the *Cereidae*, distinguished by the flowers being produced from the side of the stem, instead of at the top, as in the *Echinocactida*. They have fleshy stems of a flattened globular or cylindrical form, divided into numerous ridges, which either run uninterruptedly from the apex to the base and bear clusters of spines at intervals, or are waved or notched, and have the spines placed in the depressions. In some species the spines are of great length. The flowers are very large, and in many species exceedingly handsome, forming a striking contrast with the ungainly appearance of the plants themselves: they have a very long tube, more or less covered with bristly or hairy scales, which increase in size towards the upper end of the tube, and at length merge into sepals, the sepals in their turn passing into petals. The stamens are arranged in two series, the inner attached to the bottom of the tube, and the outer growing to the tube throughout its whole length, and becoming free at the orifice, forming a circle around it. The thread-like style, scarcely longer than the stamens, is surmounted by a many-rayed stigma. Between twenty and thirty species, natives of Bolivia, Chili, Mexico, Brazil, and Texas, are described. [A. B.]

**ECHINOPTERYX.** The name of a Mexican shrub, constituting a genus of *Malpighiaceae*, with yellow flowers in terminal clusters, and which are jointed to the stalks supporting them. The calyx is without glands; the petals five, stalked, of unequal length; stamens ten, all fertile, the filaments united into a tube at the base, the anthers hairy; ovary three-lobed, densely hairy. The fruit consists of three indehiscent spiny carpels. [M. T. M.]

**ECHINOSPERMUM.** A genus of *Borragnaceae*, distinguished by having a salver-shaped corolla, which has the throat closed

by five small scales; and three-edged nuts, with the anterior face margined and often bordered with one or more rows of hooked prickles; and by the inner angle of each of the four carpels adhering by its whole extent to a central column. They are hairy herbs resembling *Myosotis*, with narrow leaves and small blue flowers, in bracteated scorpioid racemes. The species are most abundant in the temperate regions of the northern hemisphere. *E. Lappula*, which is one of the erect-fruited species, has been found in England at Southwold, but doubtless an accidental introduction. [J. T. S.]

**ECHIUM.** A genus of *Doragnaceae*, distinguished by its tubular bell-shaped corolla, open at the throat (without scales or platts), and with an irregular limb, bearing some resemblance to that of some of the labiates. They are bristly or hairy plants, generally distributed, especially abundant in the Mediterranean region, where most of the species are herbaceous, and in the Canaries, where the greater number are shrubby. The flowers are usually large, in small curled spikes, arranged in a compound spike or panicle. *E. vulgare*, the common Viper's Bugloss, is a very rough plant with strap-shaped leaves, narrow at the base, and bright blue flowers whose stamens exceed the corolla: this occurs throughout Britain. *E. violaceum* is not found in Britain proper, but is common in Jersey; its flowers are much larger, more purple, with shorter stamens, and the leaves clasp the stem by a broad base. [J. T. S.]

**ECLAIRE, or ECLAIRE GRANDE.** (Fr.) *Chelidonium majus*. — **PETITE, or ECLAIRETTE.** (Fr.) *Ranunculus Ficaria*.

**ECLIPTA.** A genus of erect or prostrate annual or biennial weeds of the composite family, approaching dahlias in the structure of their flowers, but widely different in habit, and pretty equally distributed over all tropical countries. The leaves are usually opposite and lance-shaped, with entire or toothed margins, and the white stalked flower-heads, growing one to three together, proceed from the axils of the leaves, and are about half an inch across. The receptacle is flat and furnished with bristle-like scales, between the florets. The achenes of the ray-florets are triangular, those of the disc compressed; and the pappus is either absent altogether, or when present reduced to a minute toothed border. [A. A. B.]

**ECOSTATE.** Not having a central or strongly-marked rib or costa.

**ECTADIUM.** A genus of South African *Asclepiadaceae*, containing a single species, an undershrub with opposite coriaceous leaves, and small yellow flowers in sub-axillary racemes. The calyx is five-parted; the corolla salver-shaped with five oblong unequal lobes; the staminal crown of five lanceolate included scales; the stamens in-

cluded, free, their anthers densely hairy at the back; and the pollen-masses addressed to an oblong truncate corpuscle. The stigma is pentagonal and apiculate. The follicles are smooth, slender, obtuse, and divaricate, with comose seeds. [W. C.]

**EUTOCARPÆÆ.** A natural order of dark-spored *Alga*, consisting of olive-jointed threadlike seaweeds, whose spores are mostly external, attached to the branchlets or formed in a swelling of their substance. It differs principally from *Chordariæ* in the less compound frond and external spores. The fructification is often of two kinds in the same species. They are most abundant in temperate regions, though several are found in warm seas. [M. J. B.]

**ECTOARPUS.** A genus of dark-spored *Alga*, with a branched threadlike jointed soft flaccid frond, and remarkable for the different aspects assumed by the fruit. The secondary form is disposed in podlike bodies, which are variously articulated. A good many species are found on our coasts, and are more easily distinguished by their fruit than by the character of the frond. The cells of the pods produce zoospores. It is not quite certain whether the endochrome of the so-called spores is ever resolved into zoospores. *Ectocarpus* is known from *Sphacelaria* by the less elegant branching, and the soft not rigid threads. These are sometimes collected in bundles by the action of the waves, but never essentially combined, as in *Mesoglossa*. [M. J. B.]

**ECTONEURA.** *Polybotrya*.

**ECTOZOMA.** A genus of *Atripacæ*, represented by a shrub, native of Ecuador, of somewhat climbing habit, and with flowers in terminal panicles. The calyx is thick, bell-shaped, with five triangular erect divisions; corolla fleshy, tubular, somewhat dilated in the middle, its lobes roundish, and overlapping before expansion; stamens five, with very short filaments attached to a thin hairy ring surrounding the ovary; stigma globular. The fruit is unknown. [M. T. M.]

**ECUELLE D'EAU.** (Fr.) *Hydrocotyle vulgaris*.

**EDDOES.** The tuberous stems of various araceous plants, as *Colocasia esculenta*, *antiquorum*, &c., *Caladium bicolor*, *violaceum*, and others.

**EDDYA.** A genus of *Boraginææ* from Texas and New Mexico, containing a small much-branched very hispid prostrate undershrub with crowded leaves and solitary axillary white flowers; corolla salver-shaped, naked at the throat; stamens inserted at the apex of the tube of corolla; nuts ovate, cohering by their internal angles, mucate. [J. T. S.]

**EDENTATE.** Not having teeth.

**EDGED.** When one colour is surrounded by a very narrow rim of another.

**EDGWORTHIA.** A genus of plants be-

longing to the *Thymelacææ*, named by C. A. Meyer in honour of Mr. Edgworth, an Indian botanist. The flowers have a single perianth, the limb of which is divided into four ovate blunt lobes. There are no perigynous scales, but one emarginate hypogynous one; stamens eight, nearly sessile, arranged in two distinct lines, one above the other; ovary covered with hairs, one-celled, containing a single suspended ovule; style threadlike, ending in an elongated awl-shaped stigma. There are two species of the genus, *E. chrysantha*, found in Chusan by Mr. Fortune, a shrub with yellow flowers, and oblong-lanceolate leaves of a very dull green, covered with hairs closely pressed to the surface, and *E. Gardneri*, found in Nepal. [J. H. B.]

**EDMONSTONIA.** A group of plants named after Thomas Edmonstone of Shetland, naturalist of the Herald, formerly included in *Samydacææ*. It has a coloured persistent four-cleft perianth; four stamens inserted into the bottom of the calyx, the filaments free, the anthers intorse; and a free one-celled ovary with three parietal placentas, and numerous ovules. There is one known species, *E. parviflora*, which is a shrub ten to twelve feet high, native of Darien. It is now referred to *Tetrathylacium* (*Violacææ*). [J. H. B.]

**EDRAIANTHUS.** The generic name of plants belonging to the order of bellworts, and characterised by the number five prevailing in the flower; the stamens free, their filaments broad at the base; the ovary with two or three cells; and the seeds ovate and plain. The name is defined from Greek words signifying 'sessile or stalkless flower'. The species are natives of Southern Europe, and usually in the form of small tufted herbs with narrow alternate leaves, which are often furnished with stiff hairs; the individual flowers are stalkless but grouped in heads. [G. D.]

**EFFLORESCENT.** The action of beginning to flower.

**EFFOLIATION.** The removal of leaves.

**EFULCRATE.** Said of buds from below which the customary leaf has fallen.

**EGENOLFIA.** *Polybotrya*.

**EGERIA.** A genus of *Hydrocharidacææ* from South America, consisting of water plants with the habit of *Anacharis*, having dichotomous branches and verticillate linear leaves with finely serrated margins. The spathe of male flowers is axillary and sessile, the flowers themselves resembling those of *Hydrocharis*; female flowers unknown. [J. T. S.]

**EGG-PLANT.** *Solanum esculentum* (*Melongena*) and *ovigerum*.

**EGG-SHAPED.** The same as Ovate.

**E'GILOPE.** (Fr.) *Agilops*.

**E'GILOPS.** (Fr.) *Quercus Agilops*.

**E'GLANTIER.** (Fr.) *Rosa Eglanteria*.

— JAUNE. *Rosa lutea*. — ODORANT, or

ROUGE. *Rosa rubiginosa*. — SAUVAGE.  
*Rosa canina*.

EGLANDULOSE. Not having glands.

EGLANTINE. *Rosa Eglanteria*, and  
*Rubus Eglanteria*; also applied to *Rosa*  
*rubiginosa*, the Sweet Brier.

EGREVILLE. (Fr.) *Lactuca perennis*.

EHRETIACEÆ (*Ehretiads*). A natural order of dicotyledonous plants belonging to De Candolle's subclass *Corollifloræ*, and to Lindley's echin alliance of perigynous exogens. The plants are closely allied to the borageworts, differing in their terminal style, perfectly concrete four-celled ovary, and drupaceous fruit. Trees, shrubs or herbs covered with rough hairs; leaves alternate, simple, without stipules; inflorescence scorpioid; aestivation imbricate. Calyx inferior with five divisions; corolla gamopetalous and tubular; stamens five, alternate with the corolline segments. Ovary on a circular disk, two to four-celled, with a terminal style or two-lobed stigma. Fruit fleshy, with a single seed in each cell. Chiefly tropical plants, though some occur in the South of Europe, others in the Southern States of America. They have scarcely any important properties. A few are febrifugal, astringent, and alterative. The Peruvian heliotrope, cultivated since 1740, has a delightful odour. There are fifteen known genera and about 230 species in the order. Illustrative genera: *Ehretia*, *Tournefortia*, *Heliotropium*. [J. H. B.]

EHRETIA. A genus of *Ehretiaceæ*, consisting of tropical trees or shrubs with paniculate or corymbose flowers which are usually white. The calyx is deeply five-parted, the corolla salver-shaped with a five-parted limb, the stamens five, the ovary four-celled, and the fruit a berry-like drupe with two or four stones, each containing a single seed. *E. buxifolia*, an Indian shrub with sessile wedge-shaped shining scabrous leaves and axillary few-flowered peduncles, is employed as an alterative, and is also regarded as an antidote to vegetable poisons. *E. serrata*, an Indian tree, with oblong serrated smooth leaves and fragrant flowers, yields tough light and durable wood. [J. T. S.]

EHRHARTA. A genus of grasses belonging to the tribe *Oryzææ*, distinguished by the inflorescence being in compressed spikelets, three-flowered; flowers nearly together; the two lower neutral, one-paled, thick and keeled, mucronate or with short awns: the terminal hermaphrodite, two-paled; stamens six; styles two, with feathery stigmas. The species belonging to this curious genus are mostly natives of the southern hemisphere, South Africa, and New Holland. [D. M.]

EICHORNIA. A genus of *Pontederaceæ* from South America. Kunth restricts *Pontederia* to the species in which two of the cells of the ovary are abortive, while *Eichornia* has a three-celled three-valved

many-seeded capsule. They are aquatic plants with roundish rhomboidal stalked radical leaves, and a scape with a single leaf or spathe like the root-leaves, and a spike of lilac or blue flowers. *E. spectiosa*, widely spread on the continent of South America, is a very handsome plant with a ten or twelve-flowered spike and the petioles of the leaves curiously swollen, the enlargement consisting of very loose spongy tissue. It is often cultivated in stoves under the name of *Pontederia asurea*, or *crassipes*. [J. T. S.]

EICHWALDIA. A genus of the *Heurmutiaceæ*, distinguished by its many-leaved calyx. The only known species, *E. oxiana*, found on the Oxus river, which flows into the Caspian Sea, is a scrubby little bush with white stems, alternate linear fleshy leaves, and few somewhat racemed flowers, almost half an inch across. Inside the calyx of numerous round bract-like leaves are five-clawed petals, numerous stamens, and an ovary crowned with five styles. The fruit is a little capsule opening by five valves, apparently one-celled at top, but distinctly five-celled below. [A. A. B.]

ELACHISTA. A small genus of parasitic *Algae* allied on the one hand to *Ectocarpus*, and on the other to *Chordaria*. In *E. scutellata* the threads are so intimately combined with the tissue of *Himanthalia lorea* that it is impossible to say where the one begins and the other ends. Indeed, did not the species produce distinct fruit, they might justly be reckoned as mere transformations of the cells of the mother plant. [M. J. B.]

ELÆAGIA. A genus of lofty cinchonaceous trees, natives of the Cordilleras. The flowers are arranged in terminal clusters: they have a cup-like calyx; a corolla with the short tube bulging at top, and a spreading limb; and stamens with very short filaments, and broadly ovate anthers. The globose capsule is ribbed, and bursts into two or four valves. These trees are remarkable for the quantity of green resinous or waxy matter which is secreted by the stipules, which invest the unexpanded buds. This resin is collected by the Indians, and is employed by them to varnish boxes and many other useful or ornamental objects. For this purpose it is purified by immersion in hot water; its fragility is then removed by chewing it till it becomes ductile; and after these processes it acquires a yellow tint, and is ready to receive the various colours imparted by adding colouring matter to it when melted. The resin when thus prepared and coloured is laid on in thin layers by the aid of heat and pressure, and by means of differently coloured layers placed one upon another and cut out into various shapes, a sort of design is produced. To procure a metallic lustre on the objects covered with the varnish, the Indians first coat the surface with a layer of silver foil. The natives speak of the tree producing this resin, *E. utile*, as the Wax tree or

Varnish tree. M. Triana, to whose account in the *Bulletin de la Soc. Bot. de France*, 1868, p. 500, we are indebted for these particulars, dwells with justice on the importance of developing this manufacture, and of cultivating this and allied plants producing similar secretions in other localities. The temperature of the district where the *Blasgia* is chiefly found ranges from 54° to 74° F. Some better method of preparing the resin might no doubt be adopted. [M. T. M.]

**ELÆAGNACEÆ (Oleasters).** A natural order of monochlamydeous dicotyledons, belonging to Lindley's amental alliance of diclinous Exogena. Trees or shrubs usually covered with scales or scurf, having exstipulate entire leaves, and usually imperfect flowers. Staminate flowers in catkins, arising each from a scale-like bract; perianth of two to four leaves, sometimes united; stamens three, four, or eight. Pistillate and perfect flowers with a tubular perianth and a fleshy disk; ovary free, one-celled, with one ovule; fruit a crustaceous achene, enclosed within the succulent perianth. Chiefly natives of the northern hemisphere. Represented in Britain by *Hippophaë rhamnoides*, the sea buckthorn, a spiny shrub which grows well near the sea, and forms a good fence; it is covered with silvery scurf, which is a beautiful object under the microscope; its fruit is sometimes eaten. *Elæagnus parvifolia* bears clusters of red edible berries, mottled with scales. The fruit called in Persia *zinzeyd* is the produce of *Elæagnus orientalis*. Some of the plants of the order are said to possess narcotic qualities. There are four known genera and thirty species. Examples: *Shepherdia*, *Hippophaë*, *Elæagnus*. [J. H. B.]

**ELÆAGNUS.** The Oleaster or Wild Olive tree. A small tree native of the southern countries of Europe and several parts of Asia, which received its name from its resemblance to the true olive, from which, however, it differs in not bearing useful fruit. The two plants in reality belong to different orders, the present plant giving name to the order *Elæagnaceæ*. *E. hortensis*, the species most commonly grown in English gardens, attains the height of from fifteen to twenty feet. The leaves are long and narrow, covered, as well as the young shoots, with stars of hairs of a hoary colour. The branches are brown and smooth, more or less spiny. The flowers are of two kinds, some containing stamens and pistils, which are four-cleft, pale yellow within; the others, with stamens and an abortive pistil, are five to eight-cleft, and of a golden yellow within; all are axillary, two or three together on short stalks, and fragrant. It flowers in May, and ripens its fruit, which is of a red-brown colour, something like a small date, in August. The blossoms, which are produced in great abundance, perfume the air for a considerable distance round. For this reason it is a most desirable tree for a lawn or shrubbery. French,

*Olivier de Bohême*; German, *Wilde Olebaume*. [O. A. J.]

**ELÆIS.** A genus of palms comprising the Oil Palm of Africa, and another closely allied American species. They have thick trunks of no great height, indeed the American species creeps along the ground, and bears a tuft of large pinnate leaves, with strong prickly stalks. The male and female flowers are borne in distinct heads, generally upon different trees, but occasionally upon the same; each head consisting of numerous little branches of minute flowers, gathered together into a dense mass and enclosed while young in two complete spathes. The males are packed very close together, so that the branches resemble catkins; the females are spread farther apart. The fruit, which is yellow or bright red, is irregular in form, gener-

*Elais guineensis*.

ally angular and somewhat three-sided, and larger at the bottom than the top. It consists of an outer coating of fibrous oily flesh, surrounding a hard nut. *E. guineensis*, the African Oil Palm, which yields the celebrated palm oil, is a native of tropical Western Africa, where it is found in great abundance; and from whence it has been introduced into the West Indies. It grows twenty or thirty feet high, the trunk being covered with the remains of the stalks of dead leaves. The fruits are borne in dense heads, measuring a foot and a half or two feet long, and from two to three feet in circumference, the individual fruits being about an inch and a half long, by an inch in diameter. The part yielding the palm oil is the outer fleshy coating of the fruit, but the seed, which is enclosed in a hard shell, likewise affords an oil, small quantities of which occasionally come to this country. Commercial palm oil is about the consistence of butter, of a bright orange-red colour, and has a rather pleasant violet-like odour when perfectly fresh. It is obtained by boiling the fruits in water and skimming

off the oil as it rises to the surface; and as its production and preparation is carried on solely by the negro population, who bring it to the merchants in small quantities for sale, it is anticipated that ere long the Negro kings will find the trade in palm oil more profitable than that in human beings. In 1880 the imports of palm oil into the United Kingdom amounted to 804,326 cwts., representing a money value of 1,786,895*l*. The chief use to which this substance is applied is for the manufacture of candles, and it is the principal article used for that purpose in the extensive works of Price's Patent Candle Company; besides which it is greatly employed in soap-making, and likewise for greasing the wheels of railway carriages. In Africa it is eaten as butter, and a kind of soup is made by boiling the fruits. The hard black shell of the nut takes a fine polish, and is frequently made into rings and other ornamental articles by the negroes. [A. S.]

**ELÆOCARPUS.** A genus of *Tiliaceæ*, natives mostly of tropical parts, principally of India and Java, a few occurring in Australia and New Zealand. They either form trees, attaining sometimes the height of fifty or sixty feet, or large shrubs; they have simple leaves, and racemes of small flowers, with a calyx of five sepals, and five petals either toothed or beautifully fringed, the stamens indefinite, inserted upon a swollen lobed disk, and having long downy unequal-celled anthers, usually terminating in a bristle. The ovary is from two to five-celled, and the fruit contains a very hard rough-shelled nut, divided into as many one-seeded cells as the ovary, or sometimes all but one cell imperfect. *E. Gantrus*, a tree, growing forty or fifty feet high, is native of India and the Malay Islands, where the hard stones of the fruit are commonly used for stringing into rosaries, or for making necklaces, bracelets, buttons, heads of pins, and similar articles. *E. Hinau*, the Hinau of the New Zealanders, is a tree fifty or sixty feet high, with a trunk three or four feet thick, producing a very hard white timber, which, however, is not very valuable, being apt to split when exposed to wet or heat. The bark affords an excellent and permanent dye, varying from light brown, to puce, or deep black; it is greatly used by the natives for dyeing their garments. The pulp surrounding the stone of the fruit of this and other species is eatable; and in India the fruits of several are either used in curries or pickled like olives. [A. S.]

**ELÆODENDRON.** A genus of trees or shrubs belonging to the *Celastraceæ*, occurring in greatest numbers in S. Africa, but also represented in Australia, India, and the W. Indies. The leaves are opposite or alternate, elliptical or lanceolate and smooth; and the inconspicuous green or white flowers are disposed in axillary cymes, and have a four or five-parted calyx, a four or five petaled corolla, inserted under a fleshy ring and longer than the calyx, a like number of stamens inserted on the

margin of the fleshy ring in which the ovary, crowned with a short style and a rounded stigma, is immersed. The fruits are green fleshy drupes, sometimes about the size of a hazel-nut, but often much smaller, with a thin fleshy outer covering, surrounding a hard three to five-celled nut. *E. australe* furnishes a close-grained firm wood, which is used in N. S. Wales for turning and cabinet work; this tree attains a height of thirty to forty feet, with a diameter of eight to fourteen inches. The drupes of *E. Kubu* are eaten at the Cape. The bark and roots of *E. Rozburghii*, an Indian species, are considered efficacious in all cases of swelling, and are used externally rubbed with water. The root is also said to be powerfully astringent and useful in snake bites. [A. A. B.]

**ELÆOSELINUM.** The generic name of plants belonging to the order of umbellifers, distinguished from their allies by having each half of the fruit with five principal and four secondary ribs, two of the latter being wing-like. *E. monoides* is a native of Sicily, and occurs also in Algiers; its leaves are twice pinnate, rough on the stalks and nerves, the leaflets numerous and very narrow. [G. D.]

**ELAIO.** In Greek compounds = olive colour, a mixture of green and brown.

**ELAPHOGLOSSUM.** A genus of poly-podiaceous ferns of the tribe *Acrosticheæ*, distinguished by their simple fronds, and simple or parallel forked free veins, which are club-shaped at the apex. This defined the genus includes a large proportion of the species formerly referred to *Acrostichum*. In some of them the fronds are smooth and naked, but in others they are clothed with variously shaped and often strongly coloured scales which form pretty objects for microscopical examination. Upwards of 150 species are admitted, the larger proportion of them occurring in the West Indies and South America, a considerable number in India and the East, and others extending to the Mascaren Islands, Madagascar, the Cape, and Sierra Leone, and to Australia and the Islands of the Pacific. The fertile fronds are distinct from the sterile ones, generally more or less often very much contracted, and not unfrequently elevated on longer stalks, their under surface being entirely covered with spore-cases. [T. M.]

**ELAPHOMYCES.** Underground *Fungi*, differing from truffles by reason of the contents of the thick peridium being ultimately resolved into a mass of dusty sporidia from the absorption of the asci. They were, in consequence, for a long time associated with puffballs. We have three wild species in this country, two of which are pretty generally diffused. The peridium is either smooth or rough with warts. Of our more common species, *E. granulatus* is far less rough externally, and has a thinner peridium, which is not variegated within like *E. variegatus*. All the species appear to be involved in an intricate mass of rootlets

and spawn. They had once the reputation of being aphrodisiac, arising from a false notion as to their origin, and they are still kept by the herbalists in Covent Garden under the name of lycopodon nuts. Several species have been found in France which at present have not rewarded the researches of British mycologists. *E. granulatus* gives rise occasionally to *Cordiceps capitatus*, as does *E. variegatus* to *C. ophioglossoides*. [M. J. B.]

**ELAPHEIUM.** A genus of trees or shrubs belonging to the *Amyridaceae* (*Bursaceae*), abounding in resinous juice, and natives of tropical America. The characteristics reside in the hermaphrodite flowers, which have a persistent four-parted calyx; four petals inserted beneath an entire disc along with the eight stamens; a sessile ovary, with two ovules in each of its two compartments; and a short style with two stigmas. The fruit is a pea-shaped drupe with a thick rind, and an inner shell containing generally one seed surrounded with pulp. *E. elemiferum*, a native of Mexico, according to Dr. Royle furnishes Mexican Elemi, a greenish resin. *E. tomentosum* also yields a resin. [M. T. M.]

**ELATERIUM.** A drug prepared from the pulp of the fruits of *Ecballium agreste*, formerly known as *Momordica Elaterium*.

**ELATERS.** Cells containing a double spiral which occur in the capsules of *Jungmanniaceae* and *Marchantiaceae* in company with the spores. The young capsules contain two sets of cells, the one narrow, the other broader; the endochrome of the narrower gives rise to a single or double spiral thread, while the broader cells by transverse and longitudinal cell-division give rise to the spores. The threads in the peridia of *Trichia* resemble elaters very closely, but there is still a controversy as to their real structure. [M. J. B.]

**ELATINACEÆ** (*Water-peppers*). A natural order of thalamifloral dicotyledons, belonging to Lindley's rural alliance of hypogynous Exogens. Small annuals growing in marishes with opposite leaves, having interpetiolar stipules, and minute axillary flowers; sepals and petals three to five; stamens as many or double the number; styles three to five; stigmas capitate. Fruit a three to five-celled capsule, opening at the partitions. Seeds numerous, exalbuminous attached to a central placenta. The family is nearly allied to the chickweed order, but differs in the stigmas, the mode in which the fruit opens, and the straight not curved embryo. Lindley thinks that the affinities are chiefly with the rue family. The plants are generally distributed over the world. Some of them possess acidity, hence their English name. There are six known genera, and twenty-four species. Examples, *Elatine*, *Bergia*, *Andropogon*. [J. H. B.]

**ELATINE.** A genus of dwarf annual aquatics with rooting pipe-like stems and opposite leaves. There are two British

species, called Waterworts, both of unusual occurrence. *E. hexandra* is a minute plant barely an inch high, which grows on the margins of lakes, forming a moss-like mat sometimes extending under the water, and in dry seasons when it is left by the receding water assuming a crimson hue. The flowers, which are minute and flesh-coloured, grow in the axils of the opposite leaves. *E. Hydropiper* scarcely differs from the preceding except that the flowers are octandrous. They might be sown with advantage on the shelving banks of artificial water to conceal the unsightliness of mud. [C. A. J.]

**ELCAIJA, ARABIAN.** *Trichilia emetica*.

**ELDER.** The popular name for *Sambucus*.

**ELECAMPANE.** *Inula Helenium*.

**ELECTRA.** A genus of small Mexican bushes of the composite family, nearly allied to *Coreopsis*, but the latter has the ray florets barren, while in this genus they are female. The young twigs are four-sided and furnished with lance-shaped smooth leaves; and the yellow-rayed flower-heads, nearly an inch across, are disposed in terminal corymba. Each head is surrounded by an involucre of two series of scales, the outer very narrow, the inner broader and membranaceous; the strap-shaped ray florets are female, the tubular ones of the disc five-toothed and perfect. The achenes compressed, nearly elliptical, crowned with two bristles, or quite naked. The receptacle is furnished with golden chaffy scales. Only two species are known. [A. A. B.]

**ELEGIA.** A genus of *Ruticeae*, characterized by having deciduous sheaths, loosely panicle male inflorescence, and triangular or compressed indehiscent fruit. The three inner glumes are often longer than the three outer. The species are sedg-like plants from the Cape of Good Hope, with flowers in dense panicles. [M. T. M.]

**ELEMI.** The name of certain stimulant gum-resins, derived from various plants. —**AMERICAN or BRAZILIAN.** The gum-resin of *Icica Icariba*. —**EASTERN or MANILLA.** The gum-resin of *Canarium commune*. —**MEXICAN.** The gum-resin of *Elaphrium elemiferum*.

**ELEOCHARIS.** A genus of cyperaceous plants, belonging to the tribe *Scirpææ*, distinguished by one or two of the lowest glumes being larger than the others, and empty; bristles three to six, or wanting; nut compressed, crowned with the persistent dilated base of the joint style. The species have a wide geographical range, some of them growing within the torrid zone and others reaching nearly to the arctic. In Steudel's *Synopsis Plantarum Cyperacearum*, 118 species are described, four of which are natives of Britain. The commonest is *E. palustris*, which in many places fills up bog holes and ditches with its long-matted entangled stems. The flowers are in small brown spikes. [D. M.]

**ELEPHANTOPUS.** A genus of erect annual or perennial hairy weeds belong

ing to the composite family. About a dozen species are known, natives of America, one, however, being a common weed in most tropical countries. The alternate leaves are linear, or more generally oblong, narrowed below. The compound flower-heads, half an inch or more in diameter, are arranged in loose terminal corymbs, or in a spicate manner, each separate head having an involucre of narrow-pointed bracts, which enclose three to five white or purple tubular four-toothed florets deeply cleft on one side so as to appear palmate. The achenes are compressed, ribbed, and crowned with a pappus of numerous chaffy bristles. An infusion of the leaves of *E. Martii* is used by the Brazilians in pectoral affections, and is known as Erva Grasso; it grows from two to three feet high, and has narrow oblong root leaves, and compound flower-heads disposed in loose corymbs terminating the simple stems. The leaves of *E. scaber*, a plant very like the former in appearance, are used in Travancore, boiled and mixed with rice, for pains in the stomach, swellings in the body, &c. The twigs of *E. spicata* are used in Jamaica for making brooms. [A. A. B.]

**ELEPHANTORHIZA.** A genus composed of two Caffrarian bushes with tuberous woody root-stocks which are said to bear some resemblance to an elephant's foot. They belong to the *Mimosa* group of the leguminous family, and are most nearly allied to *Prosopis*, but differ in the nature of their pods, which are nearly straight, compressed, about six inches long, and an inch broad, and contain numerous seeds; when ripe the two valves fall away, and leave the entire rim of the pod behind. The pods in *Prosopis* are spirally twisted, and do not open when ripe. The leaves, like those of many species of *Acacia* and *Mimosa*, are bipinnate and alternate, and are made up of six to ten pairs of pinnae, each of which has eighteen to thirty pairs of linear smooth leaflets. The numerous small flowers are arranged in simple or compound spikes. [A. A. B.]

**ELEPHANT'S-EAR.** The common name for *Begonia*.

**ELEPHANT'S-FOOT.** *Testudinaria Elephantipes*; also the common name for *Elephantopus*.

**ELETTARIA.** A genus of *Zingiberaceae*, consisting of plants having much the appearance of *Amomum*, from which genus the present is distinguished by the elongated filiform tube of the corolla, by the presence of the internal lateral lobes in the shape of very small tooth-like processes, and by the filaments not being prolonged beyond the anther. They are natives of the tropical parts of India. *E. Cardamomum* furnishes the fruits known as the Small or Malabar Cardamoms of commerce. These are collected either in their wild state or from cultivated plants. In the forests of Travancore the Cardamom springs up spontaneously when the trees

are felled. In four years' time the plant attains its full development, and produces its fruits, which are gathered in November and ripened in the sun. The plant continues to yield fruit till the seventh year, when the stem is cut down, new plants arising from the stumps (*Drury*). As imported the fruits are ovate triangular capsules of a dirty yellow colour, containing several angular seeds. Three principal varieties occur in commerce, called, according to their length, shorts, short-longs, and long-longs! The seeds are used medicinally in this country, for their cordial aromatic properties, which depend on the presence of a volatile oil. In India the fruits are chewed by the natives with their betel, and are also used in bowel complaints. Ceylon Cardamoms are said by Dr. Pereira to be the produce of *E. major*. [M. T. M.]

**ELEUSINE.** A genus of grasses belonging to the tribe *Chlorideae*, distinguished by the inflorescence being in close finger-like spikelets at the apex of the rachis; glumes five to seven-flowered, the valves obtuse; pales obtuse, upper blind-toothed; scales truncate, subulate; styles two, confluent at the base. The species are mostly natives of the warmer parts of the globe, where some of them are of considerable importance. *E. coracana* is cultivated in Japan as a corn crop for its large farinaceous seeds, and also on the Coromandel coast, where it is called Natchnee. [D. M.]

**ELÆUTHEROS.** In Greek compounds—distinct, separate.

**ELISENA.** A genus of paniculiform amarillidaceous bulbs, found in Peru. They produce erect linear-lorate leaves, and scapes supporting a few flowers, the short tube of which is cylindrical, the limb reflexed, its segments linear, two of them as well as the cup and filaments declinate; the cup is cylindrical with a repand recurved margin. One or two species are known. *E. longipedala* is a pretty plant with white flowers, sometimes met with in gardens. [T. M.]

**ELIZABETHA.** A genus composed of two beautiful leguminous trees found in British Guiana, nearly related to *Brownia*; but the stamens are nine in number, three of them longer than the others and bearing anthers, the remainder sterile; while in *Brownia* they are more numerous, and all fertile. The unequally pinnate leaves of *E. princeps* are made up of twenty to forty pairs of narrow leaflets, while those of *E. coccinea* have fewer and larger leaflets. The rose or scarlet flowers are arranged in dense terminal bracted spikes from two to four inches long. The tubular calyx is five-toothed, the upper tooth broader than the others; the five narrow petals are nearly of equal length; and the nine stamens are free or shortly united at the base. The broadly linear pod is compressed and thickened on the upper edge, from three to five inches long, velvety, and containing a number of seeds. The genus was de-

dictated by Schomburgk to the Princess Royal of Prussia. [A. A. B.]

**ELLEANTHUS.** *Evelyna*.

**ELLEBORE BLANC.** (Fr.) *Veratrum album*.

**ELLERTONIA.** A Malabar climber, forming a genus of *Apocynaceae*, distinguished from *Astenia* and *Blaberopus* chiefly in having peltate seeds expanded at each end into a broad membranous wing.

**ELLIOTTIA.** A genus of *Cyrtillaceae* containing a North American shrub with alternate entire leaves and terminal racemes. Flowers with a four-parted calyx, a very deeply six-parted corolla, eight stamens with glandular filaments, and a four-celled ovary and capsule. [J. T. S.]

**ELLIPSEA cuneifolia**, the only species of the genus, is a climbing shrub, native of Malacca, and belonging to the order *Anonaceae*, in which it is distinguished by the following characteristics:—petals overlapping one another in the bud; carpels oblique, distinct one from another, and each having a single ovule attached to the ventral suture. [M. T. M.]

**ELLIPSOIDAL.** A solid with an elliptical figure.

**ELLIPTIC.** A flat body, which is oval and acute at each end.

**ELLISIA.** A genus of *Hydrophyllaceae*, containing six species of North American branching annual herbs, with opposite or alternate oblong and pinnatisect leaves, and white flowers on solitary peduncles, opposite the leaves below, and in loose racemes above. The calyx is five-parted, without reflexed appendages to the sinuses; the corolla tubular, campanulate and caducous, with ten small scales in the tube; the stamens included; the nectary surrounding the ovary, and rising into five gland-like teeth; and the capsule ovoid-globose with four seeds. This genus scarcely differs from *Nemophila*, except in wanting the appendages to the calycine sinuses. [W. J.]

**ELLOBOCARPUS.** *Ceratopteris*.

**ELM.** The common name for *Ulmus*. — of New South Wales. *Epicarpurus orientalis*. —, **SPANISH.** *Cordia Geraschanthus*, or *Geraschanthus vulgaris*; also said to be applied to *Rhamnus ventricosa*. —, **WYCH** or **WITCHE.** *Ulmus montana*.

**ELODEA.** A genus of *Hypericaceae*, differing from *Hypericum* only in having scale-like glands alternating with the bundles of stamens. *Hypericum Elodea*, which is found in various parts of Britain, is referred to this genus; and there are a few European and Western Asiatic species, and two found in the United States. Most of these are perennial smooth pea-green herbs, with opposite shortly stalked or sessile elliptical or lance-shaped leaves, furnished with transparent dots, and yellow or purplish flowers disposed in axillary or terminal few-flowered cymes. A stomachic tincture

is said to be prepared from the leaves of *H. virginicum*. Also a synonym of *Asaccharum* and *Udora*. [A. A. B.]

**ELONGATE.** Lengthened or stretched out, as it were.

**ELS, ROOD.** *Cunonia capensis*. —, **WIT.** *Weinmannia trifoliata*.

**ELSHOLTZIA.** A genus of labiate plants, distinguished by having the calyx ovate or bell-shaped, and having five equal teeth; the tube of the corolla about as long as the calyx, rarely longer, its border two-lipped, the upper slightly notched, the lower three-lobed and spreading. The species are herbs or undershrubs of little interest, natives of Eastern India and Java, rare in Central Asia. The genus was named after Elsholtz, a Prussian botanist. [G. D.]

**ELVASIA.** A genus of Brazilian shrubs belonging to the *Ochnaceae*. They have small flowers in terminal clusters, a four-leaved calyx, four petals, eight stamens, and a four-celled ovary, with an ovule arising from the base of the inner angle of each compartment. [M. T. M.]

**ELYME DES SABLES.** (Fr.) *Elymus arenarius*.

**ELYMUS.** A genus of grasses belonging to the tribe *Hordeae*, distinguished by the inflorescence being in simple spikes, very rarely branched; spikelets two to three together; glumes two, both on the same side of the spikelet, without awns; enclosing one to seven florets. In *Blondel's Synopsis* there are forty-nine species described. These have an extensive geographical range; nearly all are inhabitants of the temperate zones, but some extend even to the Arctic circle. One species, *E. arenarius*, the Sea Lyme-grass, is a native of Britain, and is useful for binding with its long creeping roots the land on which it grows. They are all coarse grasses, and of little importance for agricultural purposes. [D. M.]

**ELYNIA.** A genus of cyperaceous plants belonging to the tribe *Caritaceae*, distinguished by the scales being imbricated or slightly lapping over each other by their edges, covering a spikelet of two flowers; lower floret fertile, upper barren. Small grass-like plants, having the habit of some carices. They are mostly natives of Alpine countries, and rarely met with. [D. M.]

**ELYNANTHUS.** A genus of cyperaceous plants, belonging to the tribe *Elynochopeae*, and distinguished by the inflorescence being in close bundled spikes; flowers polygamous, the terminal one hermaphrodite; styles three-cleft, thickened and bulbous at the base; seeds triangular. The species are mostly natives of the Southern Hemisphere, South Africa, and New Holland. [D. M.]

**ELYTRANTHE.** A genus of *Loranthaceae*, containing Indian parasitical shrubs with compact abbreviated spikes of

whitish purple or orange flowers, which are inserted in the rachis, and each furnished with three bracts; petals cohering in a tube at the base; stamens six. [J. T. S.]

**ELYTRARIA.** A genus of *Acanthaceæ*, containing a few species scattered over the tropical regions of America, Africa, and India. They are stemless herbs, with entire dentate or repand radical leaves and small flowers. The calyx is four or five-parted. The corolla is two-lipped or ringent; there are two fertile and two barren stamens, all included; and the capsule contains many pitted seeds in each cell, attached to the placenta without any retinacula. [W. C.]

**EMARCID.** Flaccid, wilted.

**EMARGINATE.** Having a notch at the end, as if a piece had been taken out.

**EMBELIA.** A genus of *Myrsinaceæ*, nearly allied to *Marsa*, from which it differs in its free ovary, and from the other genera in the family with free petals in its slender racemes of flowers, which usually form a terminal panicle. It is composed of about twenty species of straggling shrubs, found in India and the islands of the Indian Archipelago, and those to the east of Africa. The alternate stalked leaves are lance-shaped, elliptical, or oval, furnished with transparent dots. The minute green, white, or pink flowers are borne in great profusion, and arranged in simple or compound racemes towards the ends of the branches; they have a five-parted calyx, five free spreading petals, opposite to which are five stamens, and an ovary crowned with a short style and rounded stigma. The berries are minute, round, and either red or black when ripe. Those of *E. Ribes*, one of the most common Indian species, with ovate-lanceolate smooth leaves, are gathered and sold to traders, who use them for adulterating black pepper, which they somewhat resemble, and have, moreover, a slight pungency, owing to a resinous substance contained in them. They possess anthelmintic properties, and are sometimes given in infusion. *E. Banaol*, another Indian species with larger elliptical and more or less downy leaves, is useful in various ways. The young leaves in combination with ginger are used as a gargle in cases of sore throat; the dried bark of the root is a reputed remedy for the toothache; and the berries mixed with butter are used as an ointment, which is applied to the forehead as a specific for pleuritis. [A. A. B.]

**EMBLICA.** A genus of *Euphorbiaceæ*, differing only from *Phyllanthus* in the more deeply divided style, and in the nature of the fruit, which is about the size

is found wild and cultivated in various parts of India and the Indian Archipelago. It is a tree sometimes of large growth, but more generally of twenty to thirty feet, with an abundance of simple alternate linear leaves, which are smooth, and arranged on slender branches in a distichous manner, so that they appear like leaflets of pinnate leaves; in their axils the little green flowers are found in cymes, the females mixed singly with the males. The latter have a six-parted calyx, no petals, six stamens, and three to five stamens united into a short column. The females, with a similar calyx, have a cup-shaped disc, and an ovary crowned with a style which has three thick recurved two-lobed branches. In Borneo, the bark and young shoots are used to dye cotton black, for which purpose they are boiled with alum. The fruits are often made into a sweetmeat with sugar, or eaten raw as a condiment, but they are exceedingly acid. The wood is hard and valuable, as it resists damp well. In India the bark is used in tanning, and the root-bark mixed with honey is applied to inflammation of the mouth. The fruits also are used as a pickle, or preserved in sugar; when ripe and dry they are given in cholera, diarrhoea, &c., under the name *Myrobalani Emblicæ*. The seeds are employed in nausea and bilious affections, and given in infusion in fevers. An infusion of the young leaves mixed with sour milk is also used in dysentery. The natives of Travancore have a notion that the plant imparts a pleasant flavour to water, and therefore place branches of the tree in their wells, especially when the water is charged with the accumulation of impure vegetable matter. [A. A. B.]

**EMBOLUS.** A plug; a process which projects downwards from the upper part of the cavity of the ovary in *Ameria*, and closes up the foramen of the ovule.

**EMBOTHRUM.** A small genus of *Proteaceæ*, having an elongated tubular calyx, bursting longitudinally, and a sub-globose four-cleft limb bearing the anthers, which are sessile, on the concave points of the segments. The fruit is a leathery many-seeded follicle. They are trees or shrubs with simple, oval or lanceolate entire leaves, greyish on the under-side, and red generally smooth flowers. They are found in the Western and Antarctic portions of South America. [R. H.]

**EMBRACING.** Clasping with the base. The same as *Amplexicaul*.

**EMBRYO** (adj.) **EMBRYONAL.** The rudimentary plant, engendered within a seed by the action of pollen. — **FIXED.** A leaf bud.

**EMBRYO-BUDS.** Spheroidal solid bodies,

being usually a dry membranous capsule. *E. officinalis*, or, as it is sometimes called, *Phyllanthus Emblica*, is the only species, and

**EMBRYOTEGIUM, EMBRYOTEGA.** A little papilla, often separating as a lid,

which covers over the radicle of some kinds of embryo. It is the hardened apex of the nucleus.

**EMERICELLA.** A most curious genus, connecting, apparently like *Contiocybe* and some others, the myxogastrous Fungi with *Caliciei*. The stem consists of a spongy central column, giving off threads which have gonidia like those of *Panula*, and resembling some species of *Palmella*, to which we shall have occasion to recur hereafter. These bodies become blue when treated with iodine. The spores are purplish, furnished with very long spines, seated in the same plane, and inclosed in a globose peridium. The only species has been found on decaying leaves of *Euphorbia nerifolia* at Secunderabad. A figure will be found in Berkeley's *Introduction to Cryptogamic Botany*, p. 341. [M. J. B.]

**EMERUS.** (Fr.) *Coronilla Emerus*.

**EMEX.** A genus of *Polygonaceæ*, closely allied to *Rumex*, from which it is distinguished by the perianth segments being united at the base, and by the flowers being polygamous. *E. spinosus*, the only species, is a salt marsh annual, of the Mediterranean region, the Cape of Good Hope, and the Antilles. In habit it closely resembles *Rumex pulcher*, except that the leaves are broadest in the middle, and the perianth has much larger spines when the fruit has arrived at maturity. [J. T. S.]

**EMILIA.** A small group of composite plants, separated from *Cuculia*, and consisting mostly of annuals, represented by *E. sagittata*, the *Cuculia coccinea* of gardens. They are natives of India, China, and the South African islands. The flower-heads are subcorymbose, the florets being all tubulose, and in the common garden forms either orange, scarlet, or yellowish. The lobes of the florets are linear elongate, and the pentagonal achenes are ciliated at the angles, and crowned with a many-rowed pappus of filiform hairs. [T. M.]

**EMMENANTHE.** A genus of *Hydrophyllaceæ*, containing a single species from California. It is an elegant erect herb with alternate pinnatifid leaves, and pendulous flowers in erect racemes, the calyx being five-parted, the corolla campanulate and persistent, and the stamens included. The ovary is surrounded by a small disc, and the capsule is oblong, and two-celled from the meeting of the enlarged placenta in its centre. [W. G.]

**EMPETRACEÆ** (*Crowberries*). A natural order of monochlamydeous dicotyledons belonging to Lindley's euphorbial alliance of delicious *Exogens*. Shrubs with heath-like evergreen exstipulate leaves, and small axillary flowers which are usually imperfect. Perianth of four to sixahypogynous persistent scales, the innermost sometimes petaloid and united. Stamens two to three, alternate, with an inner row of scales. Ovary free in a fleshy disk, two to nine-celled. Fruit fleshy, with two to nine nucules; seed solitary. Natives

chiefly of the northern parts of Europe and America. A few are found in the South of Europe, and even at the Strait of Magalhaens. The order is represented in Britain by *Empetrum nigrum*, the black crowberry, the fruit of which is eaten in northern countries, and is used by the Greenlanders to prepare a fermented liquor. The leaves and fruit of some of the plants are somewhat acid. There are four known genera, and five species. Examples:—*Empetrum*, *Corema*, *Ceratiola*. [J. H. B.]

**EMPETRUM.** Crowberry or Crakeberry. Small evergreen heath-like plants of the order *Empetraceæ*, distinguished by the following characters: calyx of three leaves with six imbricated scales at the base; three petals, and as many stamens; berry depressed, containing from six to ninebony seeds. *E. nigrum*, the badge of the McLeans, is a small procumbent much-branched shrub, with rough wiry branches and small narrow leaves, the edges of which are so much recurved as almost to form a tube. The flowers are of a dark red colour, small and situated in the axils of the upper leaves, and are succeeded by brownish-black berries, about the size of juniper berries, of a firm fleshy substance, and insipid in taste. A native of moors and the sides of boggy hills throughout the north of the Eastern continent, and the islands towards America. In Great Britain it is most abundant on the Scottish hills, where it affords abundant food to the moor-game, and is also found in the moorland districts of the north of England. Its berries are eaten by the Highlanders and Russian peasants, and are considered wholesome. Boiled in alum-water, they furnish a dingy purple dye, and Linnaeus states that they are used by the Laplanders for dyeing otter and sable skins black. *E. rubrum*, a native of the extreme south of South America, has red berries, which are said to be pleasant to eat. It is most abundant along the sandy coast. Both species are easy of cultivation as bog plants, but are slow growers. French *Camarine*; German *Rauchbeere*. [G. A. J.]

**EMPHYSEMATOSE.** Bladdery, resembling a bladder.

**EMPHYSOPUS.** A name formerly applied to a little perennial herb of the composite family, which is common on pasture lands in Tasmania, and in habit and form of leaves a good deal resembles the common daisy. The flower-heads, however, supported on naked stalks, one to three inches long, are not more than a quarter of an inch in diameter, and the leaves are clothed with a soft down. The plant is now placed in *LAGNOSPORA*: which see. [A. A. B.]

**EMPLEUROSMA.** The name of a small shrub of the rue family, a native of Swan river, and having leathery linear leaves, rolled under at the margins, and unisexual flowers, the males with a four-parted calyx, and eight stamens, whose anthers

are tipped with a gland. It is now better known as *Dodonaea pinnatifida*. [M. T. M.]

**EMPLEURUM.** A genus of *Eutaceae* consisting of one shrubby species native of S. Africa. It has oblong glandular serrulated leaves, and axillary flowers, solitary, or in twos or threes, having a four-cleft calyx, thickened at the base, no corolla, and four stamens, opposite to, and longer than the lobes of the calyx, with anthers having a gland at the top. The ovary is solitary, one-celled, terminating at top in a long horn, the style lateral, as long as the horn-like extremity of the ovary; ovules two. The horned capsule is one-seeded. *E. serrulatum* is a pretty greenhouse shrub with pinkish flowers. [M. T. M.]

**ENARTHROCARPUS.** A genus of *Cruciferae* from the coasts of the Mediterranean; it is allied to *Raphanus* but with a different pod, which breaks across into only two parts, the lowermost of which is persistent, short, obconical with one to three seeds, the uppermost long and knotty, with numerous seeds. Rough annuals with lyrate-pinnatifid root leaves, toothed stem leaves, and elongate racemes of yellow or purplish flowers. [J. T. S.]

**ENCALYPTA.** A genus of mosses belonging to the natural order *Encalyptet*, distinguished by the large funnel-shaped persistent veil which covers the capsule. *E. vulgaris* is a remarkable moss, and occurs here and there on the tops of walls, though not so general as some other wall mosses. The capsule in this genus is either even or grooved; the peristome is either single, double, or altogether wanting. The genus is almost exclusively confined to Europe and North America, though there are traces of it in Chile, Peru, and Kumaon. It is the only genus of the order. [M. J. B.]

**ENCEPHALARTOS.** A genus of *Cycadaceae*, having tall cylindrical trunks, with a terminal tuft of pinnate thick spiny leaves. The male flowers, like those of *Cycas*, are collected into a terminal stalked cone, consisting of a number of oblong wedge-shaped scales, with anthers on their under-surface; while the female flowers are collected in terminal stalked cones, consisting of peltate stalked scales, on the under-surface of which the ovule is placed, as in *Zamia*. The interior of the trunk, and the centre of the ripe female cones, contain a spongy farinaceous pith, made use of by the Caffers as food, and hence the trees are called by the name of Caffer-bread. [M. T. M.]

**ENCHOLIRIUM.** A name applied to a genus of *Bromeliaceae*, represented by a Brazilian herbaceous plant, with tufted spiny leaves, and clustered flowers, with a calyx of three short equal segments, a corolla of three petals, and six hypogynous stamens, with curved filaments dilated at the base. The ovary is free; the style triangular with three stigmas. [M. T. M.]

**ENOKHA.** Shrubs, or less frequently trees, forming a genus of *Piperaceae*, cha-

racterised by the bracts of the inflorescence, which are hood-like and bent inwards. Stamens five to seven, placed round the ovary; filaments persistent, the anthers kidney-shaped, deciduous. Ovary sessile, sometimes prolonged at the top; stigmas three to five. Fruit aromatic, berry-like, with a thick rind. The roots of *E. unguiculata* and *E. glaucescens* are used medicinally in Brazil. [M. T. M.]

**ENDECA.** In Greek compounds=eleven.

**ENDIVE.** *Cichorium Endivia*.

**ENDIVE PETITE.** (Fr.) *Cichorium Endivia angustifolia*.

**ENDOCARP.** The lining of a carpel; the inner surface of a fruit, representing at that time the upper surface of a carpelary leaf. The stone of a cherry is its endocarp.

**ENDOCARPEI.** A natural order of lichens, in which the capsule-like fruit is constantly immersed in the foliaceous or crust-like frond. The walls of the fruit moreover are pale and never carbonised as in *Verrucariae*. The best known species are *Endocarpion minutum*, which is so common about waterfalls, presenting a peltate leathery greenish frond tinged with red below; and *Pertusaria communis*, which is still more common on smooth-barked trees, especially the oak and the beech, and which by a peculiar degeneration produces the white patches which, according to their more or less mealy condition, are referred to the now exploded genera *Vriolaria* and *Leyraria*. [M. J. B.]

**ENDOCHROA.** A supposed interior layer of the cuticle.

**ENDOCHROME.** The colouring matter of plants. A term applied to the contents of the cells, especially amongst *Algae* and *Fungi*, though frequently applicable to the simple structures in phanogams. The colour of flowers, funguses, &c., depends generally upon the colour of the endochrome, the cell wall itself being hyaline. In *Algae* and *Fungi* it frequently acts an important part, being either concentrated into a single spore or zoospore, or resolved into a definite or indefinite number of either, while at times it gives rise to spermatozooids. [M. J. B.]

**ENDOGENE.** A large class of plants to which the names of *Monocotyledones* and *Amphibryae* are also given. They have a cellular and vascular system—the latter exhibiting spiral vessels. Their stem is endogenous, that is, increases in diameter by addition of woody vessels towards its interior, the outer part being the oldest and densest (hence the name *Endogens* or inward-growers); bundles of woody, spiral and pitted vessels are scattered throughout the cellular tissue; there is no pith, no separable bark, no woody rings or zones, and no true medullary rays. The age of woody *Endogens* cannot be determined by counting concentric rings as in *Exogens*. The leaves are usually con-

tinuous with the stem, and do not fall off by articulations; when at length they separate their bases leave marks or scars at definite intervals on the stem, as seen in palms. The stems of endogens are often subterranean, in the form of corms, rhizomes, or bulbs. The leaves have stomates, and their venation is usually parallel, though in a few cases it is slightly reticulated. The flowers have stamens and pistil, and three-membered symmetry. The ovules are contained in an ovary, and the embryo has one cotyledon or seed-lobe, whence they are called monocotyledonous.

The class has been divided into two subclasses: 1. *Petaloides* or *Florida*, in which the flowers consist either of a coloured perianth or of scales arranged in a whorl; 2. *Glumifera*, in which the flowers, in place of sepals and petals, have imbricated bracts or scales called glumes. Lindley has added a third subclass called *Diclyogenes*, on account of the net-veined leaves. Among the *Petaloides* there are three sections: 1. *Epigynæ*, having perfect flowers and a superior perianth, as orchids, gingers, irids, amaryllids, &c.; 2. *Hypogynæ*, having perfect flowers and an inferior perianth, as lilies, rushes, and palms; 3. *Incompletæ*, with imperfect flowers without a proper whorled perianth, as screw-pines and arums. Among *Glumifera* there are included the two orders of grasses and sedges.

Permanent endogenous stems are well illustrated by palms. In these the hardest part is on the outside, and the trunks are usually unbranched, and are limited as regards their increase in diameter. They increase principally by forming a crown of leaves, and if this growing point is destroyed they die. Some Endogens, as *Dracenas*, attain a great diameter of stem, and divide in a forked manner. [J. H. B.]

**ENDOGONIUM.** The contents of the nucleolus of a *Chara*.

**ENDONEMA.** A Cape of Good Hope shrub belonging to the *Pentaceæ*. Its leaves are flat and overlapping; the flowers axillary, solitary, with a coloured tubular perianth divided into four short lobes, and four stamens, inserted into the top of the perianth tube, alternately with its lobes. The ovary has four compartments, each containing four ovules, the upper pair ascending, the lower pendulous. [M. T. M.]

**ENDOPHLOEUM.** The liber of bark; the inner layer, containing woody tissue, lying next the wood.

**ENDOPHYLLOUS.** Formed from within a sheathing leaf; as the young leaves of endogenous plants.

**ENDOPLEURA.** The innermost skin of a seed-coat.

**ENDOPTERA.** A genus of *Compositæ*, nearly related to *Crepis*, but differing in the achenes of the ray florets having a wing on their inner face. There are but two species, *E. Diocoridis* and *E. aspera*, both annual branching weeds of S. Europe

and Asia Minor, and in appearance much like our species of *Crepis*. The generic name refers to the wings on the inner face of the achene. [A. A. B.]

**ENDOPTYLE.** Said of an embryo whose plumule is rolled up by the cotyledon, as in endogens.

**ENDORHIZAL.** That kind of germination in which the original radicle forms a sheath round the first root which comes from within the former.

**ENDORHIZEÆ.** A name applied by Richard to endogenous or monocotyledonous plants, on account of the mode in which the young root is developed. The embryo of these plants, when it germinates or sprouts, usually sends out from a definite point a bundle of rootlets, which pierce through the integument, and are covered each by a sheath called coleorhiza. This is well seen in the sprouting of the grains of grasses. The embryo is hence called endorhizal, meaning root within. [J. H. B.]

**ENDOS.** In Greek composition = within, or in the inside of anything.

**ENDOSMOSE.** That force which causes a viscid fluid lying within a cavity to attract to itself a watery fluid through an organic membrane.

**ENDOSPERM.** The albumen of a seed.

**ENDOSTOME.** The aperture in the inner integument of an ovule.

**ENDOTHECIUM.** The lining of an anther.

**ENEMION.** An herbaceous perennial belonging to the *Ranunculaceæ*, with five petal-like deciduous sepals, and from two to six carpels, which when mature are arranged in a stellate manner, and contain two oval seeds. *E. biternatum*, the only species, grows to about the height of six inches, and bears flowers about the size of *Anemone quinquefolia*. It is a native of Kentucky, Ohio, &c. [C. A. J.]

**ENERVIS.** When there are no ribs or veins visible.

**ENGELHARDTIA.** A genus of *Juglandaceæ*, numbering about ten species, found in India, Java and the Philippine islands. They are trees with pinnate leaves a good deal like those of the walnut, and inconspicuous flowers disposed in drooping spicate panicles, the outer and shorter branches of which bear sterile flowers, the inner fertile. These are succeeded by the little fruits, which are about the size of a pea, each seated on the base of a three-lobed beautifully veined and coloured bract. The beautiful catkin-like spikes of these bracted fruits are often more than a foot long, and hang very gracefully among the foliage. [A. A. B.]

**ENGELIA.** A genus of *Acanthaceæ*, containing two species, natives of Columbia. They are climbing undershrubs, with one-flowered axillary peduncles. The calyx is

reduced to a mere ring. The corolla tube is bent, and the limb fissured in front and parted into five roundish lobes; there are four didynamous stamens, with a rudimentary fifth. The ovary is one-celled, with one ovule in each cell; and the fruit is a fleshy one-celled drupe with a single seed. [W. G.]

**ENGELMANNIA.** A genus of *Euphorbiaceae*, found in Texas and the neighbouring states. It is nearly allied to *Croton*, but differs in having fewer stamens, and in its little capsular fruit, about the size of an orange-pip, being composed of two not three cocci. *E. Nuttalliana*, the only species, is an erect branching herb one to two feet high, with alternate stalked oval leaves, silvery-white underneath. The minute flowers are disposed in little clusters in the forks of the branches, the males and females together. The genus bears the name of Dr. Engelmann, of St. Louis, an American botanist. A composite plant has also been dedicated to him, but that now bears the name *Angelandra*. [A. A. B.]

The name is also applied to a section of *Ouscut*, elevated into a genus by Pfeiffer, containing those species which have a four or five-cleft monosepalous calyx, and a capitate stigma, and in which the capsule dehisces at the apex. [W. C.]

**ENGLISH MERCURY.** *Chenopodium Bonus-Henricus*.

**ENGRAIN.** (*Fr.*) *Triticum monococcum*.

**ENHALUS.** A genus of *Hydrocharidaceae*, allied to *Stratiotes*, from which it differs chiefly in having the inner segments of the perianth linear. It is found in the estuaries of the rivers, in Ceylon and other Indian Islands. The leaves are radical, linear, serrated at the apex, and the spathe of the female flowers is two-leaved with a bearded keel. [J. T. S.]

**ENKYANTHUS.** An elegant glabrous shrub, with deciduous leaves and showy red flowers, often tipped with white. It is a native of South China, and has been introduced into our gardens. It forms a genus of *Ericaceae* of the tribe *Andromedaceae*, distinguished by a campanulate five-lobed corolla, ten stamens having the anther-cells tipped with awn-like points and opening longitudinally to the base, and a free hard five-celled capsule opening locally to the base in as many valves. The flowers are terminal, pedicellate and drooping, issuing, several together, from a tuft of coloured bracts. *E. quinquefolius* is probably the only species known, for *E. reticulatus* appears to be only a slight variety of it.

**ENKYLLA.** A genus of *Ocuvritaceae*, consisting of Indian climbing herbaceous plants, with pedate downy leaves, having somewhat spiny margins, and small flowers arranged in panicles. The male flowers have a five-fold calyx and corolla, and five stamens completely united into one parcel; the female flowers have a similar calyx and corolla, and an inferior ovary, with a single pendulous ovule in each of the two or three

compartments. Fruit berry-like, of the form of a pea. [M. T. M.]

**ENNEA.** In Greek compounds = nine.

**ENSATÆ.** A name given by Linnæus to a natural order of monocotyledonous or endogenous plants, including *Iris*, *Gladiolus*, *Antholysa*, *Ixia*, *Sagittarium*, *Commelyna*, *Xyris*, *Eriocaulon*, and *Aphyllanthes*. These plants are now distributed over five separate orders. [J. H. B.]

**ENSIAO.** *Sempervivum glutinosum*.

**ENSIFORM, ENSATE.** Quite straight, with the point acute, like the blade of a broad-sword, or the leaf of an *Iris*.

**ENTADA.** A genus of Leguminous plants containing nearly a dozen species of climbing tropical shrubs, which have twice-pinnated leaves, and flowers produced either in spikes at the bases of the leaves, or in bunches at the ends of the branches; these flowers have a bell-shaped calyx, five white or yellow petals, and ten stamens. The most remarkable feature of the genus is the extraordinary length of its pods, which are flat and woody, divided into numerous joints, each containing one large flat polished seed. In *E. scandens*, a native of the tropics of both hemispheres, the pods often measure six or eight feet in length. The seeds are about two inches across, by half an inch thick, and have a hard woody and beautifully polished shell, of a dark brown or purplish colour. In the tropics the natives convert these seeds into snuff-boxes, scent-bottles, spoons, &c., and in the Indian bazaars they are used as weights. Occasionally they are sent to this country and are hawked about the streets of London under the name of West Indian Filberts, but they are not eatable. Sometimes they are conveyed by the great oceanic currents to the shores of the west of Scotland and the Orkneys, and they are occasionally carried as far as the Loffoden Isles and the Norway coast. [A. S.]

**ENTANGLED.** Intermixed in so irregular a manner as not to be readily disentangled, such as the hairs, roots, and branches of many plants.

**ENTELEA.** A genus of *Tiliaceae*, peculiar to New Zealand, and represented by a single species, *E. arborescens*, a small branching tree from five to ten feet high, with large alternate heart-shaped or three-lobed leaves, and white flowers, somewhat like those of a small dog-rose, disposed in little umbels which terminate the branches of an axillary or terminal panicle. They have a four or five-leaved calyx, a like number of somewhat crumpled petals, and numerous fertile stamens. The four to six-celled capsular fruits are about the size of a hazel nut. In New Zealand the light wood is used by the natives as floats for their nets. *Spermannia*, to which the plant is most nearly allied, differs in having numerous sterile stamens intermixed with the fertile ones. [A. A. B.]

**ENTEROMORPHA.** A genus of green-

spored *Algae*, comprising those species of *Ulva* which have a tubular frond, whether simple or more or less branched. The most general species, *E. intestinalis*, known by its bullate crisped fronds, occurs in fresh as well as salt water, *E. compressa* being the more common species on tidal rocks, and having simple or branched narrower fronds, dilated above. The species run closely into each other, and are probably too much multiplied. [M. J. B.]

**ENTIRE.** Having no kind of marginal division.

**ENTOPHYTE.** A plant which grows from within others, as some rhizanthus and fungals.

**ENULA-CAMPANA.** (Fr.) *Inula Helonium*.

**EOUSE.** (Fr.) *Quercus Ilex*.

**EOUVE.** (Fr.) *Pinus Cembra*.

**EPACRIDACEÆ** (*Epacrids*). A natural order of corollifloral dicotyledons, included in Lindley's erical alliance of hypogynous Exogens. Shrubby plants, with usually alternate simple leaves; flowers regular and perfect, in spikes or racemes; corolla gamopetalous; stamens five, equal in number to the lobes of the corolla; anthers one-celled, opening by a longitudinal slit. Ovary superior, five-celled, with five scales, distinct or combined at its base. Fruit either fleshy or capsular; embryo with albumen and very small cotyledons. There are two sections of the order: 1. *Epacrea*, with a capsular many-seeded fruit; 2. *Styphelia*, with a drupaceous one-seeded fruit. The plants are natives of the Indian Archipelago and Australia, and represent the heaths in those countries; but they differ from true heaths (*Erica*) in their pentamerous symmetry, their anthers being one-celled without appendages, and in the attachment of the stamens and the corolla.

They are cultivated in greenhouses for the beauty of their flowers. Some yield edible fruits. The berries of *Leucopogon Richi*, called native currants, are said to have supported the French naturalist Riche, who was lost for three days on the south coast of New Holland. *Astroloma humifusum* is called the Tasmanian cranberry. There are 32 known genera, and 330 species. Examples:—*Epacris*, *Dracophyllum*, *Styphelia*, *Leucopogon*. [J. H. B.]

**EPACRIS.** A large genus typical of the *Epacridaceæ*, distinguished by having a coloured calyx with many bracts, a tubular corolla with a smooth limb, stamens affixed to the corolla, and a five-valved many-seeded capsule. They are branched shrubs with the leaves lanceolate or cordate, generally sharp-pointed, and the flowers axillary, white red, or purple, usually in leafy spikes. The species are distributed over the extra-tropical portions of Australia, Tasmania and New Zealand, and many of them, from the abundance and beauty of

their flowers, are deservedly great favourites in the greenhouse. There is very much diversity in the habits of the plants. In *E. pulchella*, *E. rigida*, and *E. microphylla*, the leaves are very small, and the flowers white.

*Epacris grandiflora*.

In *E. grandiflora* the leaves are much larger, heart-shaped and sharp-pointed, the flowers nearly an inch in length, of a brilliant reddish purple at the base, and pure white at the apex. In *E. impressa*, *E. ruscifolia*, and *E. tomentosa* the flowers are of a deep rose-colour; while in *E. niven*, *E. obtusifolia*, *E. heteronema*, and *E. paludosus* they are large and of a pure white, the plants having narrow lanceolate sharp-pointed leaves. The New Zealand species are rather inconspicuous in their flowers. [R. H.]

**ÉPEAUTRE.** (Fr.) *Triticum Spelta*.

**EPERUA.** The Wallaba, *E. falcata*, a large timber tree, is the best known member of this genus of Leguminous plants. It has pinnate leaves composed of two or three pairs of leaflets; and its red flowers are borne in drooping long-stalked bunches. The calyx consists of four thick concave sepals with their bases connected, the upper sepal being broader than the others; the corolla is a solitary roundish fringed petal, inserted into the middle of the calyx; and there are ten stamens. The curiously curved flat pod bears some resemblance to a hatchet, and generally contains from three to four very flat seeds. The tree is abundant in the forests of British Guiana, where it attains a height of fifty feet, with a girth of about six feet. The timber is of a bright red-brown colour, marked with whitish streaks, hard and heavy, but rather coarse-grained. In consequence of the readiness with which it splits, it is commonly employed in Demerara for shingles, palings, &c., and being impregnated with a resinous oil, it is very durable. The bark of the tree is bitter, and the Indians employ a decoction of it as an emetic. They also use the gum as an application to cuts. [A. S.]

**EPHYRE.** (Fr.) *Hieracium*. —  
**ORANGÉE.** *Hieracium aurantiacum*.

**EPHEBE.** A curious and anomalous genus proposed by Fries, which, after oscillating between lichens and sea-weeds, was for a time joined with *Byssoides*, but whose real affinities were quite unintelligible till the discovery of the fructification, which clearly places it in close conjunction with *Lichina* and its near allies. The frond consists of branched threads composed when young principally of large brownish cells more or less perfectly disposed in transverse rows, and often divided vertically or horizontally into four. In this condition it seems to indicate an intimate relation with the algal genus *Scytonema*. In older branches, however, there is a distinct cellular tissue both external and within the layer of large cells, and towards the extremities the branchlets swell and contain nuclei, like those of *Dothidea*, filled with a gelatinous mass consisting of fertile asci, each of which contains eight sporidia, while in other similar swellings nuclei are produced whose gelatinous contents produce myriads of granules, supposed to be the male fruit of the plant. The plant is therefore clearly a lichen, allied to *Collema* and *Lichina*, receding from the common type in the nature of its gonidia, which depart from the usual green tint, and seem to be propagated like such genera as *Hæmatococcus*. The species, which are not numerous, occur on irrigated rocks and stones. They are, as known at present, confined to the temperate regions of the northern hemisphere. [M. J. B.]

**EPHEDRA.** A genus of *Gnetaceæ*. The plants have stamens and pistils in separate flowers: the staminate flowers in catkins and with a membranaceous perianth; the pistillate flowers terminal on axillary stalks, within a two-leaved involucre. The fruit is a succulent cone, formed of two carpels, with a single seed in each. They are branching shrubs, natives of the sandy sea shores of temperate climates in both hemispheres. The branches are slender, erect or pendulous; leaves very small, scale-like, articulated and united into a sheath at the base. There are twenty-five known species. *E. distachya* abounds in the southern parts of Russia; its fruit is eaten by the peasants and by the wandering hordes of Great Tartary. The branches and flowers of some of the *Ephedras* have been used to stop bleedings and discharges. [J. H. B.]

**EPHÉMÉRINE.** (Fr.) *Tradescantia*.

**EPHEMERUM.** *Tradescantia*.

**EPHEMERUS.** Enduring but a day.

**EPHIPPIUM.** A name applied by Blume to certain epiphytal orchids now referred to various genera, such as *Boldophyllum*, *Sarcopodium*, and *Otrhopetalum*. The most notable species is *Sarcopodium grandiflorum* from New Guinea, which has creeping wiry stems with four-sided pseu-

do bulbs at intervals, and a solitary flower and leaf; the flower, borne on a stalk, is said to be eight inches across, and of a pale yellowish-green colour. [A. A. B.]

**EPI.** In Greek compounds = upon.

**EPIAIRE.** (Fr.) *Stachys*. —, **GRANDE.** *Stachys sylvatica*.

**EPIBLAST.** A small transverse plate (a second cotyledon), found on the embryo of some grasses.

**EPIBLEMA.** An epidermis consisting of thick-sided flattened cells.

**EPIBLEMA grandiflorum** is a terrestrial tuberous rooted orchid of W. Australia, with a slender erect stem eighteen inches high, bearing a single grassy leaf with a few sheathing bracts, and terminating in a raceme of from one to five pretty blue flowers, each about an inch across. According to Dr. Lindley, the genus, which belongs to the tribe *Neottieæ*, differs from *Thelymitra*, of which it has the habit, not only in the clawed lip with long slender processes at the base, but also in the anther bed not being cucullate. [A. A. B.]

**EPICALYX.** The involucrellum, or external series of envelopes beyond the calyx, as in *Malva*.

**EPICARP.** The outermost layer of the pericarp, corresponding with the under side of the carpellary leaf.

**EPICEA.** (Fr.) *Abies excelsa*.

**EPICHARIS.** A genus of *Meliaceæ*, comprising certain trees, natives of the Molucca Islands, which, added to the general characteristics of the order to which they belong, present the following distinguishing features: corolla of four spreading or reflected petals; stamens eight, their filaments united so as to form a tube, the upper margin of which is divided into eight notched lobes, and encloses the anthers; ovary sessile, four-celled, enclosed within the tube of the stamens. Fruit a capsule bursting by two or four divisions, each compartment containing a single seed provided with a fleshy arillus. [M. T. M.]

**EPICHILE.** The upper half of the lip of an orchid, when that organ is once jointed or strangulated.

**EPICLINAL.** Placed upon the disk or receptacle of a flower.

**EPIDENDRUM.** A vast genus of South American orchids, numbering more than 300 species, and exhibiting great diversity of growth. They are mostly epiphytes on trees, whence the generic name, though not a few are terrestrial. The stems are elongated and leafy in some, and reduced to a pseudo-bulb in others; the leaves are leathery in texture and usually strap-shaped; and the flowers are either solitary or disposed in axillary or terminal spikes, racemes, or panicles. According to Dr. Lindley, the essential character of the genus resides in the lip being more or less united by a fleshy base to the edge of a column, which

is hornless, and considerably elongated, but not petaloid and winged; in the pollen masses being four, equal, compressed, with as many pulverulent caudicles folded back on them; and finally, in the presence of a cuniculus more or less deep at the base of the lip. *E. nemorale*, often misnamed *terre-cosum*, is one of the handsomest in cultivation. It is a Mexican plant, with ovate pseudo-bulbs bearing two glossy strap-shaped leaves, and panicles of handsome rosy flowers, each about one and a half inch across, the lip streaked with lines of a darker colour; it takes its name from the minute rough points on the branches of the panicle. Similar in size and colouring of flower is *E. Skinneri* from Guatemala, but it has elongated stems, the flowers arranged in drooping terminal racemes, and the lip with three yellow crests. Perhaps the most desirable species is the Mexican *E. vitellinum*, from its brilliant deep orange-coloured and long-enduring flowers: it has oblong pseudo-bulbs with two short leaves, and a flower scape six to twelve inches high, the individual flowers about an inch in length. Then we have *E. cuspidatum*, notable for its very large yellow flowers, with a curious trilobed lip, the central lobe linear, and the two lateral crescent-shaped with beautifully fringed borders. To the same group belong *E. ciliare* and *E. nocturnum*, the first smaller in all its parts, with greenish flowers, the latter destitute of the fringe to the lip, and emitting a very agreeable odour in the evening. The singular colouring of the flowers in *E. prismatocarpum* renders it attractive, the ground colour being yellow-green with many dark purple blotches across the sepals and petals, and the lip pink. It has ovate pseudo-bulbs with a leathery strap-shaped leaf a foot long, and the flowers are in many-flowered scapes. A. A. B.]

EPI D'EAU. (Fr.) *Potamogeton*. — DE LAIT or DE LA VIERGE. *Ornithogalum pyramidale*. — DU VENT. *Agrostis Elycaventi*. — FLEURI. *Stachys*. — SAUVAGE. *Asarum europæum*.

EPIDERMIS. The true skin of a plant below the cuticle.

EPIDERMOID. Belonging to the skin.

EPIGEA. The generic name of shrubs of the heathwort order, characterised by having three leaflets on the outside of the five-parted calyx; and by the corolla being salver-shaped, five-cleft, with its tube hairy on the inside. The name, derived from Greek words signifying 'upon the earth,' is sufficiently expressive of the mode of growth or trailing habit of the species. One of them, *E. repens*, a native of North America, has been long known in cultivation; it is an ornamental procumbent shrub, with fragrant flowers, usually white with a reddish tinge. [G. D.]

EPIGENOUS. Growing upon the surface of a part, as many fungi on the surface of leaves.

EPIGEOUS. Growing close upon the earth.

EPIGONE. The membranous bag or flask which incloses the spore-case of a liverwort or scale-moss when young. Also the nucule of a *Chara*.

EPIGYNIUM. East Indian shrubs, so named, in consequence of the disc which surmounts the ovary. They constitute a genus of *Vacciniaceæ*, known by their five-parted flowers, bell-shaped or cup-shaped corolla, ten separate stamens, and five-celled ovary containing many ovules, and surmounted by a five-lobed disc, as well as

*Epigynium leucobotrys*.

by the limb of the calyx. The fruit is succulent. *E. acuminatum*, a greenhouse shrub, has racemes of richly-coloured red flowers. *E. leucobotrys*, another species in cultivation, has a tuberous root like a yam, and the berries are white and wax-like; hence the name. [M. T. M.]

EPIGYNOUS. Upon the ovary; a term applied when the outer whorls of the flower adhere to the ovary, so that their upper portions alone are free and appear to be seated on it, as in umbellifers, myrtals, campanals, &c.

EPILEPIE. A genus of the composite family allied to *Coreopsis*, but differing in having applied to the outer surface of each wingless achene a three-toothed chaffy scale. The only known species, *E. rudis*, is an erect hispid Mexican herb with opposite pinnatisect leaves, whose stems are terminated by a corymb of numerous yellow-rayed flower-heads, each about an inch across; these have an involucre of two series of scales, neuter ray-florets, those of the disc tubular and perfect. The compressed achenes crowned with two short awns. [A. A. B.]

EPILINELLA. A section of *Oussea*, containing those in which the calyx consists of five fleshy sepals, keeled on the back, and with membranaceous margins

united at the base. It has been raised to a generic position by Pfeiffer. [W. C.] *Oxyacantha*. — DU CHRIST. *Palturus aculeatus*. — NOIRE. *Prunus spinosa*.

ÉPINETTE ROUGE. (Fr.) *Larix americana*.

ÉPINE-VINETTE. (Fr.) *Berberis vulgaris*.

EPILITHES. The name of a small herbaceous plant, which covers the rocks in certain parts of the island of Java, and is described by Dr. Blume as belonging to *Nyctaginaceae*, though his description seems rather to apply to a plant of some other order. The flowers are monœcious, four-parted, the females without petals; ovary inferior with one ovule; stigma four, brush-like; fruit berry-like. [M. T. M.]

ÉPINARD. (Fr.) *Spinacia*. — BLANC DU MALABAR. *Basella alba*. — D'HIVER. *Spinacia spinosa*. — DE HOLLANDE. *Spinacia inermis*. — DU MALABAR. *Basella rubra*. — FRAISE. *Blitum virgatum*. — IMMORTEL. *Rumex Patensia*. — SAUVAGE. *Chenopodium Bonus-Henricus*.

EPILOBIUM. A somewhat extensive genus of mostly perennial herbaceous plants belonging to the order *Onagraceae*, among which they are distinguished by their flowers having eight stamens, and by

EPIPACTIS. A genus of terrestrial orchids, consisting of erect herbs with fibrous roots, and a leafy stem, bearing a loose simple raceme of purplish-brown or whitish flowers occasionally tinged with red. The peduncle is spreading, without any spur; the petals and sepals are nearly similar; the lip free from the column, thick and concave at the base, the terminal portion broad and petal like, with two protuberances at the base; the column short with a terminal anther. There are but few species, natives of the temperate regions of the northern hemisphere. Two only are British: *E. latifolia*, not unfrequent in woods and shady places, but usually singly, attaining two feet in height or even more, the lower leaves ovate, the upper ones small and narrow, the flowers varying from green to a dingy brown, and hanging in a long loose one-sided raceme; and *E. palustris*, which is more local, although abundant in particular spots, and is not so tall, but a more showy plant, the leaves narrower, the racemes more compact, with larger slightly drooping flowers, the sepals pale greenish-purple, the petals and lip white, more or less streaked with pink.

found in all situations, by rivers, in woods, or on waste ground, and some are Alpine. In habit they are mostly erect and but little, if at all, branched; the leaves are narrow and opposite, frequently toothed at the base; and the flowers, which are either axillary or in terminal spikes, are generally of a purple hue, apparently stalked, but in reality supported on the slender rudimentary capsule. There are several British species, most of which are unpretending weeds; but *E. hirsutum*, a tall species growing from four to six feet high, is frequently ornamental to the banks of rivers and ponds. The flowers of this plant are large and of a delicate pale pink, with a conspicuous four-cleft white stigma. The whole plant is downy, soft and clammy, exhaling a peculiar acidulous scent, which has gained for it the popular name of Codlins and Cream. *E. angustifolium* is not often found truly wild, but is a common ornament of cottage gardens, when, if suffered to range at its will, it soon overpowers all other herbaceous vegetation. It is sometimes planted with advantage in shrubberies when luxuriant undergrowth is desired, but should not be admitted into a small garden, as it is most difficult of eradication. In this plant the leaves are scattered and destitute of all pubescence, and the flowers are irregular, large, rose-red, and grow in a terminal spike. French, *Epilobe*, *Laurier St. Antoine*, *Oster fleuri*; German, *Weiderich*. [C. A. J.]

EPIPETALOUS. Inserted or growing on a petal.

EPIMEDIIUM, Barrenwort. A genus of *Berberidaceae*, known by having the parts of the flower in fours, there being four sepals, eight petals and four stamens. They are Alpine herbs, found in Europe, Middle Asia, and Japan. *E. alpinum*, the only European species, is a low herb with a creeping rhizome, and long-stalked triternate leaves, with large ovate-cordate serrated leaflets, and panicles opposite the leaves bearing rather small dull purplish flowers, with the inner petals bulging at the base; it has been stated to grow in Scotland and the north of England, but only where planted. [J. T. S.]

EPIPEGUS. A genus of *Orobanchaceae*, containing a single species from North America. It is a brownish fleshy herb, parasitic only upon the roots of the beech, and furnished with a branched stem, and small remote scales, from the axils of which spring root fibres as well as flowers. The flowers on the upper portion of the branches are hermaphrodite and have a large corolla, but are generally barren, while those on the lower parts of the branches are small, have a short corolla, and are always fructiferous. In the hermaphrodite flowers, the corolla is ringent, compressed and four-cleft with the lower lip flat; while in the female flowers the corolla is short, absolutely four-toothed and deciduous. The capsule is small, roundish, imperfectly two-valved, with numerous ovate seeds. [W. C.]

ÉPINE BLANCHE. (Fr.) *Crataegus*

EPIPHORA pubescens is a South African epiphyllal orchid about a span high, with short ovate pseudo-bulbs bearing two or three oblong linear leaves a little oblique at the apex, and a terminal erect raceme of

numerous fragrant bright yellow flowers streaked with red, and nearly half an inch across. It is a highly desirable plant, as it keeps on flowering for nine months of the year. The relationship of the genus is with *Polystachya* amongst the *Vandeeæ*, and it differs chiefly from that genus in the four pollen masses being attached to a distinct though short caudicle. The inside of the little trident-shaped lip, which is uppermost in the flower, is bearded with long hairs. There is only one species known. [A. A. B.]

**EPIPHYLCEUM.** The layer of bark immediately below the epiderm. The cellular integument of the bark.

**EPIPHRAGM.** A membrane drawn over the mouth of the spore-case in urn-mosses, and closing it up.

**EPIPHYLLOUS.** Inserted upon a leaf.

**EPIPHYLLUM.** A small genus of *Cactaceæ*, commonly cultivated in conservatories in this country on account of the showy pink or crimson flowers. Only three species are known, all natives of Brazil, where they are generally found upon the trunks of trees. They grow two or three feet high, and have thin cylindrical stems, and branches composed of numerous short leaf-like joints growing out of one another, and resembling leaves joined together by their ends. The flowers are produced singly at the extremities of these branches, and are upright and regular in one species, but bent downwards and somewhat two-flipped in the others. The sepals and petals are numerous and coloured alike, so that they are scarcely distinguishable, though the innermost have their bases united into a tube; the stamens are numerous, arranged in two series. The fruit is a small very smooth berry, sometimes having angular ribs.

*E. truncatum* is the species most frequently cultivated in this country, and there are several garden varieties of it, distinguishable only by the size and colour of their flowers. It is a native of Brazil, particularly of the Organ Mountains, but is seldom found at a greater elevation than 4,500 feet. The flat joints of the branches are about two inches long, broad at top, but tapering towards the base, and the flowers, which are produced from the broad ends of the joints, are bent downwards, one side of the expanded part being larger than the other: they are pink, crimson, or orange-coloured, with white stamens. *E. Russellianum*, also Brazilian, is readily distinguishable from the last by its flowers being straight, and the petals expanding in a regular manner: the stamens, also, are of the same pink colour as the flower. [A. S.]

**EPIPHYTE** (adj. **EPIPHYTAL**). Plants which grow upon the surface of others, as many mosses and orchids.

**EPIPODIUM.** A form of disk consisting of glands upon the stipe of an ovary. Also the stalk of the disk itself.

**EPIPOGIUM** *aphyllum* is a curious leafless pale-coloured herb, forming a genus of terrestrial orchids. The root-stock has a number of short thick fleshy fibres like those of *Corallorhiza*. The stem, about six inches high, bears some small scale-like bracts, and three or four rather large pale yellowish flowers with narrow sepals and petals, and an ovate somewhat concave lip with a thick projecting spur underneath; the column is short, with a shortly stalked terminal anther. The species has a very wide range in Europe, and temperate Asia, but is generally very scarce, growing here and there among rotten leaves, in woods, and shady places. In Britain it has only been found in a single locality, near Tedstone Delamere in Herefordshire.

**EPIPTEROUS.** Having a wing at the summit.

**EPIRHIZOUS.** Growing on a root.

**EPISCIA.** A small genus of *Gesneraceæ*, containing six species, natives of America. They are fleshy, creeping, and rooting herbs, with opposite petiolate leaves, and solitary or aggregated axillary flowers, whose small calyx is free and five-parted, and the corolla erect within the calyx, then obliquely salver-shaped, with the limb five-lobed. The ovary is surrounded at the base by a disc, which swells behind into a gland. The capsule is membranaceous, two-celled, with numerous oblong seeds. [W. G.]

**EPISCOPEA.** *Themistoclesia*.

**EPISPERM.** The skin of a seed.

**EPISPORANGIUM.** The indusium of a fern when it overlies the spore-cases, as in *Aspidium*.

**EPISPORE.** A skin which covers some spores.

**EPISTYLIUM.** A genus of the spurge-wort family peculiar to Jamaica, containing only a couple of species, one of which is a shrub, the other a tree of about twenty feet; both have smooth alternate laurel-like leaves, and minute yellowish-green or reddish flowers disposed in little clusters or racemes, which in *E. axillare* proceed from the axils of the leaves, and in *E. cauliflorum* from the bare stems. The sterile and fertile flowers are in the same cluster, the former with four-parted, the latter with a five-parted calyx. The fruits are little oblong three-sided capsules, with three cells and one or two seeds in each. The genus is by some authors united with *Phyllanthus*, from which it chiefly differs in the four-lobed calyx of the male flowers. [A. A. B.]

**EPITHELIUM.** An epidermis consisting of young thin-sided cells, filled with homogeneous transparent colourless sap.

**EPURGE.** (Fr.) *Euphorbia Lathyris*.

**EQUISETACEÆ, EQUISETUM.** A natural order and genus of the higher crypto-

gama, remarkable for the external resemblance which they bear in habit to *Casuarina* or *Ephedra*, and as regards the heads of fructification to *Somia*. All resemblance, however, ceases there, and the natural affinities of the plants are with ferns. The plants are often perennial, new shoots being thrown up from the creeping rhizomes. The spores germinate like those of ferns, and produce a sort of prothallus, which bears archegones and antherids. The latter yield large spiral fringed spermatozooids like those of ferns. The shoots are jointed, each articulation having a toothed membranous sheath, and are often repeatedly divided, with whorls of branches and branchlets. The fructification is produced in the form of terminal cones, consisting of a number of peltate scales, each of which produces a circle of spore-cases, perpendicular to the axis, and opening by a longitudinal fissure, the walls of which consist of very delicate spiral tissue. The spores have a spiral coat, which ultimately splits up into two bodies, each with two clavate ends, and attached by their centre so as to look like four stamens. These, however, are nothing more than the unrolled spiral of which the spore coats consist.

The structure of the rhizome and of the lower part of the stem is very curious, and quite different from anything in ferns. In an early stage there is a central column of cellular tissue in the rhizome, from which eight plates radiate, being connected with an external cylinder of the same nature, and leaving between them distinct cavities. At a later period new tissue grows from the walls of the plates, and ultimately obliterates the cavities. Opposite to each of the plates is a vascular bundle, consisting of distinct annular vessels passing into spirals. In ferns, on the contrary, the vessels are mostly scalariform. In the fruit-bearing stems the cavities are more abundant with various modifications.

*Equiseta*, or Horsetails, are found in most parts of the world, though they are wanting in Australia and New Zealand. In the temperate regions they are mostly inhabitants of fields and wet places, and sometimes of loose sands, which they tend to bind together by their delicate rootlets, and have stiff erect stems capable of supporting themselves. But in warmer regions, and even in Lisbon, as *E. debile* and *elongatum*, they require the support of bushes to which they cling. They sometimes attain a considerable size, as *E. giganteum*, though never reaching the dimensions of undoubted fossil *Hydrataca*. An immense quantity of silica, amounting sometimes to half their weight when consumed, is taken up into their substance; and, according to the observations of Brewster, the particles, each of which has a double axis of refraction, are disposed in rows parallel to the axis, and occasionally forming ovals connected together like the jewels of a necklace. In consequence of this abundance of silica, like Tripoli, some of the species are used for polishing various

articles, and large quantities of *E. hyemale* are imported into this country under the name of polishing or Dutch rushes. Some of the species have been used in medicine,

*Equisetum xylochaetum*.

but their virtues are doubtful. The rhizomes contain a considerable quantity of starch, and the starch cells sometimes exhibit a kind of circulation. [M. J. B.]

**EQUITANT.** When the two sides of a leaf are brought together and adhere except at the base, where they enclose an opposite leaf whose sides are in the same state; hence they look as if they rode on each other.

**ERABLE.** (Fr.) *Acer*. — DE NORVEGE *Acer platanoides*. — DURET. *Acer opulifolium*. — JASPE. *Acer pennsylvanicum*. — NÉGUNDO. *Negundo*. — OBIER. *Acer opulifolium*.

**ERAGROSTIS.** A very extensive genus of grasses, belonging to the tribe *Festuceae*, distinguished by having the inflorescence in more or less compound or decomposed panicles; glumes four to ten-flowered; pales imbricated in two ranks, the upper reflexed with the edges turned back; stamens two or three; styles two, with feathery stigmas; seeds loose, two-horned, not furrowed. In Steudel's *Synopsis* there are 343 species described; these range more or less over the whole surface of the globe, Asia being the quarter where they mostly abound. Europe has only six species, all of which are natives of the southern portion only. The appellation is derived from two Greek words, signifying when combined Love-grass. Most of the kinds are handsome, and some of them are sufficiently hardy for being cultivated as ornamental grasses in Britain. [D. M.]

**ERANTHEMUM.** A considerable genus of *Acanthaceae*, containing nearly fifty species, widely distributed over the tropical and subtropical regions of the Old and

with on leaves, and showy often spicate flowers, whose corolla is salver-shaped, with a long

slender tube and an unequally lobed limb. There are two fertile stamens. [W. G.]

**ERANTHIS.** A highly prized little herbaceous plant belonging to the *Ranunculaceae* and allied to *Helieborus*, from which it may at once be distinguished by the more delicate texture of its leaves, and by having its solitary flowers surrounded by an involucre cleft into numerous segments. It is most commonly known by the name of Winter Aconite, because its foliage resembles that of the aconites, and its bright green involucre and pretty yellow flowers are in perfection when snow-drops bloom. Being a low-growing plant, but a few inches high, it is well adapted for the front of borders. It is perfectly hardy as to temperature, and will thrive in any soil. *E. hyemalis*, the species most generally cultivated, is a native of central and southern Europe, in moist shady places, and on hills. *E. sibiricus*, a native of Eastern Siberia, a plant of precisely similar habit, has five sepals; whereas *E. hyemalis* has six to eight. French, *Eranthis d'hiver*, *Helieborine*. [O. A. J.]

**ERASMIA.** A genus of *Piperaceae*, comprising a low-growing Mexican herb, with lance-shaped leaves, and branching spikes bearing scattered persistent peltate bracts; the filaments of the stamens are rather thick, short; anthers globular; ovary sessile, cylindrical; stigma conical. The fruit is an elongated smooth berry. [M. T. M.]

**EREMEA.** A genus of shrubs of the myrtle family, natives of Swan River, and nearly allied to *Melaleuca*, but distinguished from it by the stamens, which are either entirely detached, or more or less united into groups. The anthers are fixed more-over by their base, and not by their backs; and the flowers grow singly at the end of the branches, where they are covered with overlapping bracts. [M. T. M.]

**EREMIA.** The generic name of shrubs, natives of the Cape of Good Hope, belonging to the heathworts, having the calyx bell-shaped or somewhat globose, and the stamens more than four, usually six or eight, very rarely five. The name *Eremia* was assigned for the purpose of indicating another mark (not however confined to these plants), viz. one seed in each cell of the fruit. The species have the general aspect of heaths, with leaves three or four in a whorl, spreading or bent down, and having stiff hairs. [G. D.]

**EREMOBYRA.** A term proposed to designate that group of ferns in which the fronds are produced laterally on the rhizome, and articulated with it. See also *Desmobrya*. [T. M.]

**EREMOCARPUS.** A genus of *Euphorbiaceae*, remarkable for having its little hairy fruit, about the size of an orange-seed, composed of a single carpel, not of three, which is the usual number in the family. *E. setigerus*, so named from the bristle-like hairs on the stems, is peculiar to California,

and is the only species of the genus. It is a small, prostrate annual herb, having all its parts densely clothed with soft, white starry hairs. The stalked alternate leaves have broadly-oval obtuse blades, and the small green flowers come in dense clusters in the forks of the branches, males and females together, the females sessile. The whole plant has a strong disagreeable odour, even in a dried state. [A. A. B.]

**EREMODENDRON.** A genus of *Myoporaceae* containing a single species from New Holland. It is a beautiful tree, with long narrow lanceolate leaves, and axillary flowers on the tops of the branches. The large coloured lobes of the five-parted calyx are oblong, obovate, narrow at the base, and not changing in fruiting, while the corolla has an incurved tube, and an unequally five-lobed limb. The ovary is ovoid-oblong, compressed, and two-celled. This genus is scarcely separable from *Eremophila*, except by the peculiar lobes of calyx. [W. G.]

**EREMOLEPIS.** A genus of plants included in the order *Loranthaceae*. The flowers are dioecious, and have no petals; the staminate flowers have a tripartite calyx, with three stamens which are inserted opposite to the calycine segments; and the pistillate flowers have a tripartite calyx, an inferior ovary, a short style, and a simple stigma. They are parasitic shrubby plants, with alternate leaves destitute of a terminal scale, the staminate flowers in catkins, the pistillate in clusters. The genus is allied to the *Eubrackson* of Hooker. Two species, natives of South America, have been described, *E. punctulata* and *E. verrucosa*. [J. H. B.]

**EREMOPHILA.** A genus of *Myoporaceae*, containing four species of broom-like shrubs, natives of New Holland. They have opposite or alternate leaves, and axillary crowded or solitary peduncles supporting flowers which have a five-parted scarious calyx, and a corolla with a large tube and bilabiate limb. [W. G.]

**EREMOSTACHYS.** A genus of labiate plants distinguished by the upper lip of the corolla being elongated and helmet-like, narrow below, and hairy on the outside, the lower lip with three spreading rounded lobes, the middle being broadest. The name is derived from two Greek words signifying 'solitary' and 'spike.' The species are hardy plants of little importance. One of them, *E. laetiniata*, has been long known in cultivation as a hardy perennial, a native of dry hills in the eastern part of the Caucasian range; it has large spindle-shaped fleshy roots well adapted to resist the drought to which, in its native wilds, it is sometimes subjected. [G. D.]

**EREMOSYNE.** A genus of *Saxifragaceae* from New Holland, with matted or obovate entire root leaves, and pectinate-pinnate stem leaves; the flowers small, white, in compact dichotomous cymes; with a hemispherical calyx-tube adhering to the ovary,

and five linear petals; ovary two-celled, with solitary ovules. [J. T. S.]

**BREMURUS.** A genus of *Liliaceæ* closely allied to *Asphodelus*, but differing by having the filaments not dilated at the base and the seeds smooth. They are herbs from the Caucasus, Siberia, and Asia Minor, with fasciculate roots, linear radical leaves, and a naked scape terminating in an elongated raceme of yellow or white flowers with narrow spreading perianth segments, and exserted stamens. [J. T. S.]

**BREMUS.** A ripe carpel separating from its neighbours, and standing apart.

**ERGOT.** An affection of the seeds of different grasses in which the seed becomes black and elongated, so as to resemble in form a cock's spur, whence it derives its name. In an early stage the Ergot is partially covered with a thin crust producing abundant conidia. These conidia appear sometimes to grow like yeast globules, so as to assume the form of an *Oidium*, whence the fungus has received the name of *Oidium abortivacens*. It is at least supposed that the grains of the conidia and of the *Oidium* are identical. If the Ergot, however, is kept moist, either by excluding the outward air, or by sowing it in damp soil, different species of *Cordiceps* invariably appear, which are supposed to be the perfect state of the fungus. Ergot is a destructive disease amongst corn, but especially in rye; but it derives its greatest notoriety from its peculiar properties in producing contraction of the uterus, properties of which the surgeon avails himself for the expulsion of the fœtus and preventing hemorrhage. It is moreover combined with chloroform with a view to produce contraction without pain. Ergot is a valuable remedy in the hands of the regular practitioner, but a most formidable one in those of the quack, by whom it is oftentimes given to produce abortion. In this case a second quality comes into play, namely, that of causing dangerous gangrene, which it does where it forms a considerable portion in bread-corn, or is taken medicinally for a continuance. Instances are on record where the most frightful gangrene has ensued from its use, sometimes affecting a whole district. Ergot is often extremely abundant in our pastures, and causes sheep and cows to slip their young. No doubt many cases of gangrene in our flocks and herds are attributable to its prevalence. Ergot also occurs in *Cyperaceæ*, but the ultimate development has not yet been ascertained. [M. J. B.]

**ERGOT DE COQ.** (Fr.) *Craspedus Crugalli*.

**ERIA.** A genus of epiphytall orchids peculiar to India and the adjacent islands, and numbering about seventy species. Some are minute stemless herbs, with a solitary leaf and flower; others have creeping stems with flatish pseudobulbs and short spikes of small white or greenish flowers; whilst not a few have erect or drooping terete stems, with lance-shaped often plaited

leaves, and axillary or terminal racemes or panicles. None of the species are remarkable for their beauty, though many have fragrant flowers. The genus is nearly related to *Dendrobium*, but has eight instead of four pollen masses. It takes its name from the Greek *erion*, wool, the flowers of many of the species being clad with soft white down. The lip is usually trilobed, with a crested disc, and jointed to the much produced base of the column. [A. A. B.]

**ERIACHNE.** A genus of grasses belonging to the tribe *Avenæ*. The inflorescence of the species is panicle, the spikelets two-flowered, sessile or stalked, and hermaphrodite; glumes two, membranaceous, about equal to the short awns; stamens three; ovary smooth. There are twenty-three species described in Steudel's *Synopsis*, which are nearly all natives of the southern hemisphere, South Africa, and New Holland, where some of them are valuable as pasture grasses. [D. M.]

**ERIANThERA.** A genus of *Acanthaceæ*, containing two species, natives of India. They are low undershrubs, with few leaves, and flowers without bracts, on one or two-flowered axillary peduncles the calyx equally five-parted, and the corolla two-lipped, with the broad upper lip blind, and the lower trid. [W. G.]

**ERIANThUS.** A genus of grasses belonging to the tribe *Andropogoneæ*, scarcely differing from *Saccharum*, under which the species are included by Steudel. [D. M.]

**ERICACEÆ.** (*Heathworts*). A natural order of corollifloral dicotyledons, typical of Lindley's critical alliance among hypogynous Exogens. Shrubs or undershrubs, with evergreen, rigid, entire, whorled or opposite, exstipulate leaves; calyx inferior, four to five-cleft; corolla four to five-cleft; stamens eight to ten or twice those numbers, hypogynous; anthers two-celled, with appendages, opening by pores. Ovary surrounded by a disk or scales. Fruit capsular, rarely berried; seeds numerous, albuminous. There are two sections of the order:—1. *Ericææ*, fruit opening loculicidally, rarely septicidally; buds naked; 2. *Rhododendreaæ*, fruit capsular, septicidally; buds scaly, resembling cones.

The genus *Ledophyllum* is remarkable on account of its having a polypetalous corolla. The common heath (*Calluna*) is separated from the heaths (*Erica*) by its capsules having a septicidal and not a loculicidal dehiscence. The genus *Erica* reaches its maximum at the Cape of Good Hope. Some of the heathworts are astringent, others have edible fruit, and others, such as species of *Rhododendron*, *Kalmia*, and *Ledum*, are poisonous. *Arbutus Unedo* is the strawberry tree, common near the Lakes of Killarney. *Rhododendron arboreum*, and other species, in India, sometimes attain a height of forty feet; some species grow at the elevation of 16,000 to 18,000 feet in the Himalayas. *Rhododendron hirsutum* and *ferrugineum* grow on the Alps and Pyrenees at an elevation of 4,000 to 6,000

fect, and are called the Roses of the Alps. *Andromeda fastigiata* is called Himalayan heather. *Gaultheria Shallon* and other species yield edible baccate fruits. *Asalea procumbens* grows on the Scotch mountains, and is also a native of the Arctic regions, of the Alps, of Northern and Southern Europe, Siberia, and North America. There are about fifty known genera and nine hundred species. Examples: *Erica*, *Clethra*, *Arbutus*, *Asalea*, *Kalmia*, *Rhododendron*, *Bejaia*, *Ledum*. [J. H. B.]

**ERICA.** The generic name of shrubby plants belonging to the heathwort order, from which, indeed, the scientific designation of it, *Ericaceae*, is derived. They are distinguished from their congeners by the four-leaved calyx, and four-lobed corolla, the lower part of which is either globular or tubular and dilated; the stamens have the lobes of the anthers distinct, sometimes with an awn-like appendage, and opening by an oblong pore; the fruit is dry, four or eight-celled, many-seeded, bursting loculicidally.

The genus *Erica* comprehends a great number of species of much interest and beauty, and therefore general favourites with horticulturists, especially since the best method of growing them has been found out, and in this much credit is due to the late Mr. M'Nab of Edinburgh. There is a marked tendency to repetition of the number four in the different parts of the flower, viz. calyx, corolla, stamens, and fruit; and this is true even of the grouping of the leaves and of the flowers. The usual absence of any odour is compensated for by elegance in the general aspect of the plants, as well in their foliage as flowers, which combine to render most of the species worthy of a place in collections. In the corolla especially, the beauty of form, delicacy of aspect, and variety of tint can scarcely be surpassed. The shapes of the flower, a study for the modeller, present considerable variety of modification, being long and tubular, straight or arched, in some very small and dilated, in others smooth and brilliant, or covered with clammy hairs. As to colour, we find the purest white, passing into very pale rose, purples of various hues, red, less frequently yellow, and sometimes green. In some instances the calyx rivals even the corolla in appearance. Plants of this genus are confined to the old world; in Africa especially they abound, and the Cape of Good Hope is the main source whence we have derived those now so well known as ornaments of our horticultural collections, where, under skilful treatment, they even far surpass in luxuriance those which occur in the wild state. In Britain six species are usually counted as indigenous, only two of which are, however, widely diffused and cover immense tracts, viz. *R. Tetralix* and *R. cinerea*; the remaining four are more local and confined to the southern and western parts of the United Kingdom. The true Heath is of little importance in a medical point of view, none possess-

ing any active property. In our own country the two more common species above mentioned are used for brooms and for bedding cattle; their buds and tender shoots constitute part of the food of some of our native birds; and they often contribute largely to the formation of peat. The Scotch Heath, *E. cinerea*, is the badge of the M'Alistera, and *E. Tetralix* that of the M'Donalds. [G. D.]

**ERICAMERIA.** A small genus of the composite family, found in Oregon and California, related to *Linum*, but differing in having rayed as well as tubular florets, and also in having smooth achenes. They are dwarf resinous shrubby plants, much branched and leafy, with the aspect of heaths, the leaves awi-shaped and numerous, and the small yellow flower heads in corymbs at the ends of the branches. The smooth achenes are crowned with a pappus consisting of numerous capillary unequal bristles. [A. A. B.]

**ERICINELLA.** A genus of heathworts, having the calyx in four divisions, one of them larger than the others; corolla bell-shaped, the border deeply divided into four; stamens four, rarely five, usually with awn-like appendages; style or appendage at top of the seed vessel, ending in a shield-like surface. The name *Ericinella* is the diminutive of *Erica*, the species having the general aspect of heaths; leaves three in a whorl, flowers small and terminal, without bracts or leaflets at their base. They are small shrubs, natives of Madagascar, Tropical Africa, or Caffraria. [G. D.]

**ERIGERON.** A genus of unpretending herbaceous plants of humble stature belonging to the *Compositae*. The flowers are radiate, the florets of the ray in several rows, very narrow and of a different colour from those of the disk, which are fertile, with a hairy pappus; the involucre is imbricated with several rows of narrow scales. [Two species are natives of Britain, and a third, *E. canadense*, is a common naturalised weed growing profusely and gregariously in the neighbourhood of London, where it was first observed about 1690.] The name *Erigeron* denotes 'soon becoming old,' and is most appropriate, for in many of the species the plant, even when in flower, has a worn-out appearance, giving the idea of a weed which has passed its prime. French, *Vergette*; German, *Scharfe*. [C. A. J.]

**ERINEUM.** A name given to numerous productions which appear upon the leaves of trees and shrubs, and very rarely on those of herbaceous plants, which were formerly referred by authors to *Fusari*, but are now almost universally acknowledged to be merely diseased states of the cuticular cells. The spongy spots on the leaves of vines and lime trees afford a good example. The forms which these diseased cells assume are extremely various; and they are interesting to the physiologist, as showing the alteration to which the component cells of plants are subjected when free from the pressure of neighbouring

cells and subjected to new conditions. Illustrations will be found in the works of Corda and Greville, and a complete account in a work on the subject by Fée. *E. aurum*, which occurs on poplar leaves, is now referred to the genus *Saphris*, to which also *E. clandestinum* probably belongs. [M. J. B.]

**ERINOSMA.** A genus of *Amoryllidaceæ* containing the plant sometimes called *Leucosium verum*, an early spring-flowering herb, with ovate bulbs, linear-lorate leaves, and one-flowered scapes. The flowers are fragrant, and differ from those of the snow-drop in having petals like the sepals, white, with a yellowish-green spot outside; and from those of the snowflake in having a club-shaped style. [T. M.]

**ERINUS.** A *Scrophulariaceous* genus of one species, *E. alpinus*, a low herbaceous plant, having a five-cleft calyx, a corolla with a five-cleft equal limb, and short reflexed upper lip, and a two-celled capsule. It is a pretty little plant of tufted habit, having erect racemes of reddish-purple flowers, which are produced throughout the summer. It is a native of the higher mountains of Southern and Central Europe, and has lately become naturalised in the old bed of the river at Tanfield in Yorkshire. Several species of *Nyctaria* and *Lappula* were formerly included; and a variety with somewhat tomentose leaves is sometimes distinguished in gardens, under the name of *E. hispanicus*. [J. Br.]

**ERIOBOTRYA.** The Loquat, or Japanese Medlar, *E. (Eriobotrya) japonica*, one of the *Pomaceæ*, is a native of Japan and the southern parts of China, and is cultivated as an edible fruit in many parts of India. Kamper, who saw it growing in Japan, first made it known in 1690. It was more fully described in 1712 by Thunberg, who met with it growing near Nagasaki, Yedo, and elsewhere commonly in Japan. In that country it is called Bywa and Kuskube, in China Lo-quai. It was brought to Europe by the French in 1784, and planted in the National Garden at Paris; and three years later it was imported from Canton to Kew.

The tree, according to Thunberg, attains a large size in its native country. The leaves are evergreen, large, oblong, rugose like those of the medlar, bright green above, somewhat downy beneath. The flowers are produced in October and November, in spikes at the ends of the branches; their petals are like those of the hawthorn, but larger and perfectly white. The fruit is oval, of the size of a small apple, pale orange with a faint blush of red, the flesh pale yellow, with a sharp subacid flavour resembling that of an apple. It ripens in spring, or early in summer. The tree is hardy enough to bear the cold of our ordinary winters, but it has been killed when exposed to frosts of unusual severity, such as that which occurred in 1814, 1838, and 1860. It has very rarely produced its fruit in this country except under glass, and with the aid of artificial heat. It has not fruited at Paris in the open air; but it is successfully cul-

tivated as a standard in the south of France, and its fruit is even common in the markets of Hyeres and Toulon. At Malta it succeeds admirably. Improved varieties, as regards the size and quality of the fruit, have been there raised, and introduced into England; but in consequence of the tree naturally producing its flowers at the commencement of winter, it is not adapted for bearing fruit in the open air in this country, the blossoms being either cut off by frost, or so much checked by cold that the growth of the embryo fruit cannot go on. There is, however, no difficulty in fruiting it under glass. This was done at Blithfield in Staffordshire in 1818; and an account of the means adopted is given by Lord Bagot in the *Transactions of the Horticultural Society* (vol. 299) accompanied by a coloured plate. The plant was fruited in a pot kept in a stove during winter, the fruit ripening in March or April, two months earlier than its period of ripening in its native country. We may therefore conclude, that the amount of heat to which the plant was subjected in the stove was greater than that which prevails between the time of flowering and the ripening of the fruit in Japan. It appears, however, that the fruit artificially produced at Blithfield was of excellent quality. [R. T.]

**ERIOCAULACEÆ. (Pipewort).** A natural order of incomplete monocotyledons included in Lindley's glumal alliance among the Endogæ. Marsh plants, with narrow cellular spongy leaves, sheathing at the base, and a capitate inflorescence. The flowers are very minute, some having stamens, others pistils. Glumes two to three. Ovary superior, three, rarely two-celled, surrounded by a membranous tube; ovules solitary, orthotropical; style very short; stamens two or three. Capsule with loculicidal dehiscence; seeds solitary, pendulous, with a winged or hairy covering. The species abound in South America, and some plants of the order are found in North America and Australia.

There are ten known genera and upwards of two hundred and twenty species. Examples: *Eriocaulon*, *Lachnocaulon*, *Cladocaulon*, *Pholidica*. [J. H. B.]

**ERIOCAULON.** The typical genus of *Eriocaulaceæ*. The name is derived from two Greek words, meaning 'wool' and 'stem,' on account of the woolly character of the stalks of some of the species. Flowers dioecious, in a compact scaly head, the staminate ones in the centre, and the pistillate ones in the circumference of the head. The species are found in the principal parts of Asia, America, and New Holland. They are rare in North America. One species, *E. septangulare*, occurs in Britain, being found in the Isle of Skye and in Galway. One hundred species have been described. Some of those found in Brazil attain a height of six feet. [J. H. B.]

**ERIOCEPHALUS.** A genus of S. African *Compositæ*, comprising nearly twenty spe-

cies, which form much branched bushes, usually with linear, somewhat fleshy leaves, covered with silky hairs, but sometimes large and variously toothed, a good deal like those of some wormwoods, and like them with an aromatic odour. The white flower-heads, sometimes solitary but usually arranged in corymbs or umbels, are a good deal like those of the milfoils in size and appearance. They are remarkable for having the inner scales of the involucre clothed with long woolly hairs; these are not very perceptible when the plant is in flower, but after the flowers wither, and the anthers approach to ripeness, the heads are completely enveloped in the hairs, and look like little balls of cotton about the size of a pea. The hairs when fresh are white, but at length become rust-coloured, and are used by various birds for building their nests. [A. A. B.]

**ERIOCHLOA.** A genus of grasses belonging to the tribe *Panicææ*, now referred to *Helopus*. [D. M.]

**ERIOCHOSMA.** *Nothochlæna*.

**ERIOCNEMA.** A genus of *Malastomaceæ*, nearly allied to *Sonerila*, but having the parts of the flower arranged in fives instead of in threes. The species are dwarf hairy Brazilian herbs, scarcely a foot high, with somewhat fleshy stems, bearing near their base a few oval leaves, heart-shaped at the base, and densely clothed with rusty hairs. The small white flowers are few, and arranged in little umbels, on the end of a naked stalk. *E. marmoratum* has the leaves beautifully variegated. [A. A. B.]

**ERIOCOCCUS.** The name given by some authors to a species of *Riedia*, whose capsules are clothed with soft short wool.

**ERIOCOMA.** The Silk Grass, *E. cuspidata*, is peculiar to North America, where it is found usually in barren spots from Lake Winnipeg, west and south to New Mexico. It grows one to three feet high, has wiry leaves with the margins rolled inwards, and very lax panicles of flowers, each spikelet supported on a long slender stalk. Like the feather-grasses, to which this is nearly allied, the spikelets are one-flowered, the outer glumes are membranaceous, remarkably inflated below, and contracted suddenly at the apex into a short pointed beak. The inner glumes are very silky at the base, and end in a short awn. [A. A. B.]

**ERIOCYCLA.** A genus of *Umbelliferae*, characterised chiefly by the fruit being clothed with wool-like hair. The only species is an inconspicuous herb, a native of the Himalayas, having the leaves thrice-pinnate; the secondary divisions of the umbels somewhat capitate. [G. D.]

**ERIODENDRON.** A genus of tropical trees, referred by some botanists to the *Sterculiaceæ*, and by others to the *Malvaceæ*. It is nearly allied to *Bombax*, from which it differs in the staminal column being five-cleft, each branch bearing two or three anthers, that of *Bombax* being divided at top into an indefinite number of

filaments bearing single anthers. They have digitate leaves, and one-flowered axillary or subterminal peduncles, which are either solitary or fasciculate, the flowers being rather large, white or rose-coloured. The habit of *E. indicum* is represented in plate 13 b. [T. M.]

**ERIOGLOSSUM.** A genus of *Sapindaceæ*, nearly related to *Sapindus*, but differing in the nature of its fruits. These in *Sapindus* are made up of two or three one-seeded carpels, which are united their whole length, or slightly separate at top, so that they form one berry, while here the elliptical berried carpels, which are two or three in number, are quite free to the base. *E. edule* is a common tree in the Malayan peninsula and the neighbouring islands, extending to North Australia; it has alternate unequally-pinnate ash-like velvety leaves, about one foot long, and the small greenish-white flowers are disposed in branching panicles. The four petals are each furnished with a strap-shaped and bilobed woolly appendage on the inside near the base, the name of the genus, which signifies 'woolly tongue,' having reference to these. The wood is valuable, being strong and durable. In the only other species, *E. cauliflorum*, the racemes of flowers proceed from the old wood. [A. A. B.]

**ERIOGONUM.** A genus of *Polygonaceæ*, forming the type of a tribe distinguished by the absence of stipules, and the involucre flowers. They are natives of western North America, rarely occurring in the Southern States, or on the east coast. Herbs or undershrubs, usually woolly, with radical leaves in tufts, and alternate or tufted stem leaves. The peduncles often form a compound umbel or head. The perianth is herbaceous, six-cleft, with the segments arranged in two rows. [J. T. S.]

**ERIOLENA** (syn. *Schillera* and *Microlæna*). This genus belongs to the order *Serotiales*, tr. *Eriolenea*, in which it is notable from having perfect flowers with petals which do not wither and remain attached, but fall early, together with a column of numerous stamens in many series, all the stamens perfect, and not as in many of the family having sterile stamens (staminodia), alternating with the perfect ones. There are seven known species, all East Indian trees or shrubs, with alternate stalked heart-shaped leaves resembling those of a lime tree in form and size, and axillary or terminal panicles of rather large mallow-like yellow flowers. [A. A. B.]

**ERION.** In Greek compounds = woolly.

**ERIOPETALUM.** A small genus of *Aclepiadaceæ*, the species of which are natives of India, and form erect branching herbs with scale-like adpressed leaves, and small flowers in lateral or terminal sessile umbels. The corolla is subcampanulate and five-cleft, with long linear segments, and the staminal crown gamophyllous and fifteen-lobed; the five inner lobes rest on the anthers, the others are erect, and adhere to

the inner series. This genus agrees in habit with *Microstemma*, but differs in the form of the staminal crown: on the other hand, it resembles *Boucerosia* in the crown, but has a widely different habit. [W. C.]

**ERIOPHORUM.** A genus of cyperaceous plants belonging to the tribe *Scirpeæ*, distinguished by the inflorescence being either in single or compound spikes; glumes nearly equal, the lowest sometimes empty; bristles ultimately silky; nut, trigonous. The British species all grow on wet logs or turfy moors, where they frequently form very conspicuous masses of vegetation, in consequence of the long showy silky bristles of the flowers. The English name Cotton Grass is very expressive, the flowers of some of the species appearing like tufts of cotton. [D. M.]

**ERIOSOLENA.** A genus of *Thymelacææ*, or *Daphnacææ*. Perigone coloured, villous externally, funnel-shaped, with a four-cleft limb, the alternate segments shorter, the throat naked. Stamens eight, inserted in two rows into the upper part of the tube of the perigone, the alternate ones longer. Ovary one-celled, with a single ovule; style short; stigma capitate. Fruit drupaceous, single-seeded. Shrubs from Java and India, with alternate oblong-lanceolate coriaceous leaves, which are glaucous below; flowers in solitary axillary heads with long peduncles, and a two to four-leaved involucre. There are three species. By Malinor they are included under *Daphne*. [J. H. B.]

**ERIOSORUS.** *Gymnogramma*.

**ERIOSPHERA.** A genus of *Compositæ*, consisting of a few South African herbs, nearly related to *Helichrysium*, differing chiefly in their less numerous, and densely woolly involucreal scales. Some are unbranched, erect, and about six inches high; others much branched, with slender prostrate stems; and all have their parts clothed with a short white wool. The leaves are oboval or spatulate, and entire, and the yellow spherical flower-heads are few or numerous, and disposed in dense clusters on the ends of the stem, each being about the size of a pea. [A. A. B.]

**ERIOSTEMON.** A genus of shrubby *Rutacææ*, whose main characteristics are, a corolla of five petals which do not soon fall off, but remain on the plant for some time in a withered condition; ten hispid stamens,—hence the name of the genus, which signifies 'woolly stamen'; fruit of five carpels which separate and open by a long cleft to liberate the usually solitary seed. They are natives of New Holland, and have for the most part white or pinkish flowers. [M. T. M.]

**ERIOSYNAPHE.** A genus of umbellifers, the name of which is derived from two Greek words, signifying 'wool,' and 'junction,' or commissure, and points out a prominent character—the presence of a downy or wool-like covering near the line which indicates the junction of the two halves of the fruit. *E. longipolia* is a pe-

rennial shrub, with the divisions of the leaves long and narrow; the flowers yellow. It is a native of Siberia, along the course of the Volga. [G. D.]

**ERISMA.** A curious genus of tropical American trees, belonging to the *Vochyaceæ*, and remarkable for the enlarged calyx segments which crown the somewhat pear-shaped ripe fruit. The species are some of them upwards of 100 feet high, with smooth, opposite or whorled laurel-like leaves of a leathery texture; some are oval, pointed and entire, others oblong, attenuate below into a stalk, and notched at the apex. The pretty blue or yellow flowers, disposed in terminal panicles, smell like primroses, in some species. They are like the others in the family, very unsymmetrical, having a calyx of four or five teeth; a single nearly fan-shaped petal narrowed below into a claw; one fertile and four barren stamens; and a one-celled ovary crowned with a simple style.

The Japura of Brazil, *E. Japura*, is a tree of 80 to 120 feet, with stalked, whorled, oblong leaves, and panicles of yellow flowers. Mr. Spruce, its discoverer, thus speaks of it:—This noble tree, called by the Indians Japura, is frequent on the Upper Rio Negro, and on the Uaupés. It is said to be abundant on the Japura, and to have given the name to that river. As I came up the Rio Negro from the mouth of the Uaupés to San Carlos, in March 1853, the large heads of the Japura, clad with red fruits, were observed dotted everywhere about the forest. The kernels are pleasant eating both raw and boiled; they are also prepared in this way: having been boiled from morning till night, they are well covered up, and put into baskets in running water, where they remain two or three weeks. When at the end of this period they are opened out, they have a disagreeable stercoraceous odour. They are now beaten in a mortar until they have the appearance and consistence of pale butter. To receive this, a large cylindrical basket, three to five palms long by one in diameter, is made of strips of the trunk of the *gravatana* palm (*Iriartea pruriens*), and lined with the leaves of a *Heliconia*. The basket is placed on a stage over the fire, where it is customary to put things that require to be kept dry, and there the butter will remain good for two or three years. Japura butter (as it may be called) is eaten along with fish and game, being melted in the gravy along with the fruits of various species of *Capsicum*, which is an essential ingredient in the mohló at every Brazilian table, whether the guests be red or white. People who can get over its vile smell, which is never lost, find it exceedingly savoury. The fruits call to mind those of the Indian *Dipterocarpus*. [A. A. B.]

**ERISMA.** The rachis or axis of grasses.

**ERITHALIS.** A name applied to a genus of West Indian shrubs, in consequence of their shining deep green leaves. They are included among the *Oncchonacææ*, and have

axillary panicles of white flowers, with five or ten parted whorls, a wheel-shaped corolla, an inferior ovary with from five to ten compartments, one ovule hanging from the summit of each of the cavities. The fruit is a berry crowned by the limb of the calyx. [M. T. M.]

**ERTRICHIMUM.** A genus of *Boraginaceae*, consisting of small woolly Alpine plants forming dense cushions; racemes short, bracteate, bearing a few small bright blue flowers, with a salver-shaped corolla closed at the throat by five small obtuse scales. [J. T. S.]

**ERNESTIA.** A genus of *Melastomaceae*, represented by *E. tenella*, which grows in the mountain woods of New Granada, and is a slender suffrutescent hairy herb, with opposite stalked oval leaves, and white flowers disposed in loose terminal panicles. The form of the stamens is that which chiefly distinguishes the genus from its allies; the anthers are awl-shaped, and their connective has two erect bristle-like appendages, about the length of the anthers, and is produced below into a short spur. The genus bears the name of Ernest Meyer, a Hanoverian botanist. [A. A. B.]

**ERNODEA.** A genus of low-growing cinchonaceous plants, with lance-shaped leaves; sheathing many-parted stipules; a salver-shaped corolla, with four to six linear segments rolled back; and an inferior two-celled ovary, surmounted by a fleshy disc. The fruit is a berry, crowned by the limb of the calyx, and contains two one-seeded stones. *E. montana*, a Sicilian plant, has dark red flowers. [M. T. M.]

**ERODIUM.** Stork's Bill. A genus of *Geraniaceae*, known by having five of the ten stamens without anthers, and the tails of the carpels bearded on the inside; they coil up spirally when they spill away from the central column. The species are generally distributed; a great many of them inhabit the Mediterranean region; and three occur in Britain, of which the most common is *E. cicutarium*, which has the leaflets of the pinnate leaves deeply pinnatifid, and the flowers pink or white. *E. moschatum* is much more rare, and has the leaflets of the pinnate leaves only deeply toothed, and the flowers are smaller. [J. T. S.]

**EROPHILA.** A section of the genus *Draba*, distinguished by having the petals bifid, and the seeds numerous in each cell of the pod. The common British *Draba verna*, or Whitlow Grass, belongs to this section; it is one of the earliest flowering plants we have, and is often scarcely an inch high. [J. T. S.]

**EROSO-DENTATE.** Toothed in a very irregular manner, as if bitten.

**EROSTRATE.** Not having a beak.

**EROSE, ERODED.** Having the margin irregularly toothed, as if bitten by an animal.

**ERPETINA.** A genus of *Mcclastomaceae*,

nearly allied to *Medinilla*, but differing in the structure of the anthers. These, in *Medinilla*, open at top by a little pore, but, here they open by two slits along the inner face, from base to apex. The only species, *E. radicans*, is a smooth slender epiphytall plant, growing on the stems of trees in the Solomon Islands. The stems, about the thickness of a crow-quill, are furnished with opposite stalked elliptical fleshy leaves, the little stalked flowers being produced singly in their axils. [A. A. B.]

**ERPETION.** *Viola*.

**ERUCA.** A genus of *Cruciferae*, closely allied to *Brassica*, *Sinapis*, and *Diplotaxis*, but differing by having the beak of the fruit compressed, strap-shaped, and acute. The seeds are in two rows, as in *Diplotaxis*. Erect annuals, with lyrate-pinnatifid leaves, and rather large white or yellow flowers. The species occur in the Mediterranean region; the most common, *E. sativa*, which has large white flowers veined with purple, and very acrid leaves, is used in Southern Europe as a salad. [J. T. S.]

**ERUCARIA.** A genus of *Cruciferae*, known by its pod breaking into two parts, the lower with two cells, the upper one-celled and ensiform. The species are annuals from South-east Europe and Western Asia; the leaves pinnatifid and smooth, and the racemes of purplish or white flowers, terminal or opposite the leaves. [J. T. S.]

**ERS.** (Fr.) *Ervum Ervilia*.

**ERVA DE RATA.** A Brazilian name for *Psychotria noxia*, and *Pulicourea Maragravi*. — **MOIRA.** A Brazilian name for *Solanum nigrum*.

**ERVALENTA.** The same as *Revalenta*, a meal prepared from the seeds of *Ervum Lens*.

**ERVUM.** A genus of leguminous plants, containing about twenty species of weak-stemmed annuals, with pinnate leaves generally terminating in tendrils. It is very closely related to *Vicia*, both in general appearance and botanical characters, the principal difference consisting in the calyx of *Ervum* having narrow sharp segments of nearly equal length, and almost as long as the papilionaceous corolla, while in *Vicia* they are broader, and the two upper ones are shorter than the others. The pods contain from two to four seeds.

*E. Lens*, the common Lentil, grows about a foot and a half high, and has a weak branching stem, leaves composed of from eight to twelve oblong leaflets, and pale blue flowers borne in twos or threes. The pods are nearly as broad as long, smooth, and contain one or two seeds.

The Lentil was probably one of the first plants brought under cultivation by mankind for the purpose of affording food. It is several times mentioned in the Bible; for instance, in Genesis xxv. we read that Esau sold his birthright to his brother Jacob for a mess of red pottage, made of lentils. At the present day Lentils are still

extensively cultivated throughout most parts of the East, including Egypt, Nubia, Syria, India, &c.; and likewise in most of the countries of Central and Southern Europe, but not to any extent in England. There are several different kinds, the most common being the French and Egyptian. The former is of an ash-grey colour, large and very flat, resembling a lens in shape: in fact, the lens derives its name from the resemblance it bears to the lentil seed; while the latter is much smaller and rounder, with a dark skin, and of an orange-red

Ervum Lens.

colour inside. On the Continent, and also in India and other eastern countries, Lentils are largely employed as an article of human food, but in this country their use is not so general, although considerable quantities are annually imported. Thus, in 1855, the imports into the United Kingdom amounted to 131,892 bushels, valued at 26,379*l.*, or 4*s.* per bushel, nearly the whole of which came from Egypt. Their principal use with us is for the preparation of the so-called invalids' food, which under the names Ervalenta and Revalenta have attained no little celebrity. These articles are nothing more than lentil meal, sweetened with sugar or flavoured with salt; but under cover of their high-sounding names they are palmed off upon a credulous public at a price far above their real commercial value. As an article of food lentils rank first among the pulses, containing three per cent more flesh-forming or nutritive matter than the common pea, but like many other eatable leguminous seeds, they are very indigestible when not freed from the outer skin. [A. S.]

The generality of readers will wish to know if there is any real foundation in the widely extended belief that Lentil powder, and combinations of it with other vegetable ingredients, have the medicinal powers attributed to them. It is true, if allowance is made for some degree of exaggeration, but only in cases of indigestion. Lentil powder, made of the decorticated seeds, is reported to be a re-

medy for almost every variety of indigestion and bilious disorder, to relieve pains in the stomach, and to be so far aperient, as in most cases to obviate the necessity of habitually taking aperient medicine; and there is, in truth, no doubt that it acts as a mild deobstruent on the entire of the digestive organs, producing an increased flow of gastric juice, bile, and other secretions. But it should be distinctly understood, that these beneficial effects can only be secured by selecting lentils of the best quality, and completely depriving them of the various extraneous substances and decayed and injured seeds which they always contain, as well as of their outer skin.

The proper mode of cooking Lentils as a remedy for indigestion, &c., is boiling them for twenty minutes, or till they are quite soft (but never more than half an hour), in soup or beef-tea, to which a small quantity of salt has been previously added. In this mode of cooking them, the peculiar vegetable principles on which the remedial powers depend, a great part of which are extracted by the liquid during the boiling, are eaten with the soup, beef-tea, or other convenient vehicle; and it is probable that Lentil-powder owes part of its reputation to its being taken entire, the direction given being to mix it with milk.

Peas possess in some degree the same properties, and haricot beans in even a greater degree, but they are to some extent injured by the length of time required in boiling them. As an article of diet Lentils are extensively used in various parts of the world, and are a favourite food in the East, where the Hindoo adds them to his rice, making doubtless a salubrious mixture. Like other leguminous seeds, they contain much caseine, and constitute one of the most nutritious of vegetable products, 100 parts by analysis yielding: Water, 14.0; caseine, 26.0; starch, 35.0; sugar, 2.0; gum, 7.0; fat, 2.0; woody fibre, 12.5; mineral matter, 1.5. [B. C.]

The Lentil is easily cultivated in England, and is worthy of attention, as being capable of yielding a large supply of a highly nutritious and wholesome food. Half a pint of seed drilled in rows a foot apart, would not badly occupy a portion of the cottager's potato garden, and the seeds ground into meal would make a pottage which would be of great value in rearing a family.

We have two native species, viz. *E. hirsutum*, the Hairy Tare, and *E. tetraspermum*, the Smooth Tare. These are readily distinguished by the hairy two-seeded pod of the former, and the smooth four-seeded pod of the latter. These plants are of frequent occurrence about bushes, among which their slender stems climb for support. They are also common as agrarian weeds, especially in corn-fields, the hairy form being the most general, as being fond of all kinds of soil. Where it establishes itself amidst the wheat, it is a great pest, as it sometimes climbs about it to such an extent, as to bear it to the earth, to the great danger of the crop. The smooth

form is less common, but it is not unfrequent in clays. [J. B.]

**ERYCIBE.** A genus of climbing shrubs, containing seven species, natives of tropical Asia. They have entire leaves, and flowers in terminal panicles; the calyx consisting of five sepals, the corolla deeply five-cleft, with large bifid lobes, having a triangular sericeous part on the middle of the back, the five stamens inserted on the tube of the corolla, and the ovary cylindrical-ovoid, glabrous, and one-celled, surmounted by a large fleshy ten-ribbed stigma. The fruit is a one-seeded berry. An order, *Erycibes*, has been established for the reception of this anomalous genus. Nearly approaching *Convolvulaceae*, it differs from this order in having a sessile radiating stigma like a poppy. The sessile stigma exists in *Ebenaceae*, but in most other respects *Erycibe* has no relation with that group. [W. G.]

**ERYNGIUM.** A well-marked genus of umbelliferous plants, distinguished by spiny leaves, and hemispherical or oblong heads of sessile flowers, the base of which is surrounded by a whorl of conspicuous bracts, most frequently rigid and spiny. *E. maritimum*, Sea Eryngo, or Sea Holly, is a common plant on most of the sandy shores of Great Britain, where it is conspicuous by the glaucous hue of its short rigid leaves and stems, and its thistle-like heads of blue flowers. It has extensively creeping cylindrical fleshy roots, the gathering of which, for the purpose of converting them into a sweetmeat, was formerly an occupation of some consequence to the sea-side population. Candied Eryngo-root is still to be obtained in some places, but its medical powers, which were at one time highly extolled, are now held in no repute. The venation of this plant, as well as of other species, being remarkably strong and durable, the leaves and flowers are frequently employed as fit subjects for skeleton bouquets. *E. campestre*, is found near ballast-heaps in some parts of England, and was formerly abundant about Watling Street. Of the foreign species, which are numerous, the most worthy of notice are *E. amethystinum*, so called from the brilliant blue tint, not of its flowers only, but of the bracts and upper part of the stem; it is a native of Dalmatia and Croatia, but is frequently cultivated in English gardens; while *E. alpinum*, a smaller plant of a still more brilliant colour, is a native of the Swiss Alps. French, *Pantoucat*; German *Krausdistel*. [C. A. J.]

**ERYNGO.** *Eryngium maritimum* and *campestre*.

**ERYSIMUM.** A genus of *Cruciferae*, distinguished from the other long-podded genera, which have the radicle of the seed bent round and lying on the back of one of the cotyledons, by having the pods four-angled and elongated. The species are usually biennials, found in Europe and temperate Asia, with narrow leaves often attenuated at the base, and terminal racemes

(at first corymbs) of yellow, or very rarely white flowers. *E. cheiranthoides*, with small yellow flowers, is not uncommon in England; *E. orientale*, with amplexicaul stem leaves, and small white flowers, has occurred in some of the eastern counties; *E. Perfoliatum* and *E. arkanensium*, are handsome cultivated species, the former with rich orange-coloured flowers. [J. T. S.]

**ERYSIPHE.** A large assemblage of ascigerous *Fungi*, now broken up. The mycelium is white, or slightly tinged with brown, creeping over the green parts of plants, or more rarely, bursting through the stomates, and sending out here and there suckers which exhaust the juices of the matrix. The creeping threads send forth here and there perpendicular branches, which are articulated, and break up at the tips into large conidia, which either germinate immediately or produce a multitude of threads from the granular contents. Some of these joints occasionally become cellular and produce in their centre a multitude of minute conidia or spermatia. At different points in the creeping threads little swellings are formed, which ultimately become perithecia, and are fringed with curious appendages, which are sometimes straight and pointed with a bulb-like base, sometimes waved, sometimes hooked or incurved, sometimes repeatedly forked either with straight or divaricate branches, and sometimes end in a thick spongy body. The perithecia contain occasionally only a single ascus, as in *Sphaerotheca*, while in other genera, the asci vary in number, but are generally few, and never so numerous as in *Sphaeria*. Perithecia sometimes occur which are not distinguishable from the true, but which, instead of containing asci, yield a multitude of minute spores joined together with mucous matter. Five kinds of fructification, therefore, have been found in these plants. In an early stage, the species, which are then described as *Oidia*, constitute the white mildew so destructive to various plants, as vines, hops, peaches, &c. In this state they are easily checked by the application of sublimed sulphur, which seems to combine with the nascent oxygen to form sulphurous acid. The Vine Mould, which has for many years been so destructive, and which has been named *Oidium Tuckeri*, is doubtless a state of some *Erysiphe*, which has not been discovered. [M. J. B.]

**ERYTHRÆA.** Herbaceous plants, growing in many parts of the world, with simple or branched stems, and pink or pale yellow flowers in cymose panicles; they differ from those of the allied *Gentiana*, by their calyx being divided to the base, by their anthers, which become spirally twisted as they wither, and by the greater length of the style. *E. Centaurium* is a common English plant, in dry, sandy, or chalky soils especially; and found also throughout Europe and Central Asia. It is an annual, with erect square generally branched stems, broad egg-shaped leaves at the base, and flowers of a pale pink colour in,

a much branched cyme. This plant varies very much in the size of the flowers, the size of the leaves, and the degree of branching, so that it may be found as a simple stem half an inch high, with only a single flower, or one or two feet in height, with very numerous blossoms: hence some of the more marked varieties have been considered to form distinct species. The plant partakes of the bitter qualities of the order, and might be used in place of gentian. Besides the English species, others from the south of Europe, the Azores, &c., with yellow or pink flowers, are occasionally grown in gardens. [M. T. M.]

**ERYTHRINA.** A genus of handsome leguminous trees or shrubs, popularly known as Coral trees. They are pretty generally distributed through the tropics of both hemispheres. Some attain great dimensions, while others are dwarf bushes with woody rootstocks; a few have the stems and leaf-stalks beset with prickles. The leaves are trifoliate, with long stalks, the leaflets oval lanceolate elliptical-triangular. Many of the species are cultivated in hothouses for the sake of their beautiful large generally blood-red flowers, which are arranged in terminal racemes. In some species the tubular calyx is two-lipped or equally five-toothed, the petals all narrow, and nearly of equal length, while the keel is composed of two distinct petals. Some botanists consider that these alone should form the genus *Erythrina*. The name *Chirocalyx* is given by some authors to a few species in which the calyx is sheath-like, split above, and five-toothed at the apex; in a third group, called *Duchassaingia*, the keel is of one petal, lifted at the point, and is equal in length to the wings, which are about twice as long as the calyx, while the erect standard is broad, generally oval, and narrowed below into a claw; while in a fourth group, called *Micropteryx*, the keel is also of one petal beaked at the point, but the wings are small, generally scale-like, and included in the calyx. The pods in most species are long, narrow, round, and constricted between the seeds, which are often bright red with a black spot, and about the size of a pea. These hard red seeds are frequently strung into necklaces. The *Anacasia* of Peru, *E. Amansia*, is the only species whose pods split when ripe. This plant is described by its discoverer, Mr. Spruce, as one of the most beautiful trees of the country, attaining a height of 100 feet, and clad in spring and autumn with large flame-coloured or vermilion flowers. [A. A. B.]

*E. Caffra*, the Kaffrboom of the Dutch, or Kaffir's tree, is a native of South Africa, where it forms a tree fifty or sixty feet in height. Its trunks are commonly hollowed out and made into water-troughs and canoes. The wood is soft, but is said to be durable when tarred; and it is so light that it is used as a substitute for cork for floating fishing nets. *E. indica*, a small tree, native of the East Indies, growing about thirty feet high, is commonly cul-

tivated in India and the Malayan peninsula and islands, for supporting the weak stems of the pepper plant, for which purpose it is kept dwarf. It affords a very soft porous wood, greatly used in India for making toys, light boxes, and similar articles, which are usually overlaid with a thick coating of varnish or lacquer. In Ceylon the young tender leaves are eaten in curries. *E. umbrosa*, which attains a height of fifty or sixty feet, is a native of tropical South America, and is commonly cultivated there, as well as in some of the West India Islands, for the purpose of protecting the cocoa plantations from the effects of high winds, and at the same time to induce a proper degree of moisture in their neighbourhood. [A. S.]

**ERYTHRINE.** A colouring matter found in lichens.

**ERYTHROCHITON.** Small Brazilian Rutaceous trees, with long alternate simple fragrant leaves, and flowers placed on short jointed stalks arising from the leaf axils, in groups of two or more; the calyx is red, large, tubular; the corolla white, salver-shaped. [M. T. M.]

**ERYTHROCOCCA.** A genus of *Euphorbiaceæ*, composed of a single W. African species, *E. aculeata*, a smooth low shrub with stalked oval leaves, having short straight prickles in their axils (prickly plants are rare in the family), and little fascicles of minute green flowers, the males and females on different plants, both having a three-parted calyx. The ripe fruits, about the size of a peppercorn, are of an intense scarlet colour. [A. A. B.]

**ERYTHROLÆNA.** A genus of *Compositæ* found in Mexico, represented by a single species, *E. conspurcua*, which was introduced to English gardens about 1838, and is commonly known as the Scarlet Mexican Thistle. It is a tall plant eight to ten feet high, with rigid leaves, somewhat like those of a common wayside thistle: those at the base of the stem pinnatifid, with cut and spiny-pointed segments, and about two feet long; the stem-leaves smaller, lanceolate, with spiny teeth, and all more or less downy underneath. The flower-heads, clustered at the ends of the branches, are about three inches long, and very handsome, because of their scarlet involucrel scales. The florets are all tubular, yellow, and perfect; and the smooth achenes are crowned with a feathery pappus. [A. A. B.]

**ERYTHRONIUM.** A genus of *Liliacæ*, consisting of nearly stemless herbs, with a long narrow solid scaled bulb, and two very smooth elliptical leaves usually spotted with purple. The scape is one flowered: the flower large, nodding, lily-like, with the perianth of six separate portions, bell-shaped or recurved, the three inner segments furnished with a callous tooth on each side.

The common Dog's-tooth violet, *E. Dens canis*, has purple flowers; it is a native of

Southern Europe and temperate Asia, and is an exceedingly ornamental garden plant, as well as an early flowerer. The most common American species, *E. americanum*, has narrow perianth segments of a pale yellow colour. [J. T. S.]

**ERYTHRO.** In Greek compounds = any pure red.

**ERYTHROPHYLL.** The red colouring matter of plants.

**ERYTHROPHYSA.** A genus of *Sapindaceæ*, nearly related to *Cardiospermum*, but differing in its five-lobed bell-shaped and petal-like calyx. The only known species, *E. undulata*, is a smooth stunted South African bush, with rigid stems, furnished near the apex with unequally pinnate leaves, composed of four to six pairs of small elliptical leaflets, and an odd one; the flowers, which all seem to be yellow or scarlet, are disposed in little clusters at the ends of the twigs. The fruits are three-celled bladder capsules, of a fine red colour, and suggest the generic name, which signifies 'red bag.' The plant is sometimes called *Erythrophila undulata*. [A. A. B.]

**ERYTHROPOGON.** Two neat little erect S. African bushes form this genus of *Compositæ*, which differs from its nearest ally, *Metastasia*, in having stalked flower-heads, and sessile achenes. In *E. umbellata* the minute heath-like leaves are of a silvery white colour, rounded, linear, curiously spirally twisted, and disposed in numerous crowded bundles. In *E. umbricata* they are fewer and nearly lance-shaped. In both the top-shaped flower-heads, with white or purple florets, are few and disposed in little umbels on the ends of the twigs. The smooth beakless achenes are crowned with a pappus of one series of rough hairs, of an intense purple colour. [A. A. B.]

**ERYTHROCHIS.** A remarkable genus of leafless terrestrial orchids found in the Birman empire and adjacent islands. They are perhaps the most gigantic plants in the family. The stems of *E. scandens* are from fifty to a hundred feet long, scrambling over trees in dense wet jungles. They are of a pale dull red, furnished with brown scales which supply the place of the leaves; and the flowers are disposed in panicles or racemes, the sepals and petals whitish-yellow, and the lip tinged with pale blue. It differs from *Vanilla* in the lip being free instead of connate with the column; and from *Cyrtosia* in the capsular not berried fruit, with winged seeds. [A. A. B.]

**ERYTHROSPERMUM.** A genus of Mixands, composed of a few Mauritian and one Ceylon tree, and differing from the others in the family in having a definite number of stamens. They have smooth oval lance-shaped or oblong leaves, either alternate, opposite or whorled; and the white myrtle-like flowers are arranged in racemes or panicles. [A. A. B.]

**ERYTHROSTIGMA.** A Japanese tree, belonging to the *Anacardiaceæ*, and re-

markable for being covered with red dots; the leaves are unequally pinnate; the five-parted flowers are arranged on a much-branched panicle; the five hair-like filaments are united together at their bases; the ovary is stalked, and contains a single ovule; and the fruit is a kidney-shaped drupe. [M. T. M.]

**ERYTHROSTOMUM.** Any aggregate fruit like that of a strawberry or *Ranunculus*.

**ERYTHROXYLACEÆ.** (*Erythroxyloideæ*.) A natural order of thalictroid floral dicotyledons belonging to Lindley's sapindal alliance of hypogynous Exogens. Shrubs or trees with alternate smooth stipulate leaves, and small whitish or greenish flowers on axillary peduncles, covered at the base with imbricated scaly bracts. Sepals five, united at the base, persistent; petals five, equal, with plaited scales at their broad bases; stamens ten, monadelphous; anthers innate, with longitudinal dehiscence. Ovary three-celled, with three styles and eight capitate stigmas; ovule anatropal. Fruit drupaceous, one-seeded. They are chiefly West Indian and South American plants. Some have stimulating qualities; others have a tonic bark. The bark of *E. suberatum* supplies a reddish-brown dye. There is only one genus, *Erythroxylon*, and above seventy species. [J. H. B.]

**ERYTHROXYLON.** This genus contains numerous species, the majority natives of tropical South America and the West Indian Islands, but some occurring in Madagascar and the Mauritius. They are mostly bushy shrubs, or occasionally they form small trees.

*E. Coca* is the most interesting of the species, on account of its being extensively cultivated, and its leaves largely employed as a masticatory, under the name of Coca, by the inhabitants of countries on the Pacific side of South America. It is a shrub of six or eight feet high, somewhat resembling a blackthorn bush. The Coca leaves are of a thin texture, but opaque, oval, tapering towards both extremities, their upper surface dark green, the lower paler and strongly marked with veins, of which two, in addition to the midrib, run parallel with the margin. Small white flowers are produced in little clusters upon the branches, in places where the leaves have fallen away, and stand upon little stalks about as long as themselves.

The use of Coca in Peru is a custom of very great antiquity, and is said to have originated with the Incas. At the present day it is common throughout the greater part of Peru, Quito, and New Grenada; and also on the banks of the Rio Negro, where it is known as *Spadic*. Coca forms an article of commerce among the Indians, and wherever they go they carry with them a bag of the carefully dried leaves, and also a little bottle-gourd filled with finely powdered lime, and having a wooden or metal needle attached to its stopper. Four times a day, whatever the nature of his

occupation, whether employed in the mines, the fields, as a muleteer, or domestic servant, the Indian resigns himself to the pleasures of Coca chewing, mixing the leaves with lime or the ashes of *Cocropia*. When used in moderation Coca exerts a pleasurable influence upon the imagination, and induces a forgetfulness of all care; it is also a powerful stimulant of the nervous system, and when under its influence Indians are able to perform long and rapid journeys, and carry heavy loads, without requiring any other sustenance. But when taken in excess it produces intoxication, of a character resembling that of opium rather than alcohol, but not so violent, although the consequences of its prolonged use are quite as injurious, and very few of those who become slaves to the habit attain an old age.

*Erythroxylon Coca.*

Spruce says that an Indian, with a chew of Spadic in his cheek, will go two to three days without food, and without feeling any desire to sleep.

[A. B.]

**ESCALLONTACEÆ** (*Carpodaceæ*, *Escalloniaceæ*). A natural order of calycifloral dicotyledons belonging to Lindley's grossall alliance of epigynous Exogena. Evergreen shrubs, often odoriferous, with alternate exstipulate leaves, and axillary conspicuous flowers. Calyx superior, five-toothed; corolla of five petals, alternate with the divisions of the calyx, aestivation imbricated; stamens five, attached to the calyx, and alternating with the petals. Ovary inferior, two to five-celled, with a large central placenta and numerous ovules; style simple, surrounded at the base by an epigynous disk; stigma two to five-lobed. Fruit a capsule or berry crowned by the persistent calyx and style; seeds minute with oily albumen. [The order is considered by Bentham and Hooker as a tribe of *Asclepiadaceæ*, with which they similarly unite *Ribesaceæ*.] The species are natives chiefly of South America; but some are found in the southern parts of

Australia and New Zealand. On the mountains of South America they grow at an elevation varying from 6,600 to 14,760 feet, and form a marked region of vegetation. There are seven known genera and about sixty species. Examples: *Escallonia*, *Itea*, and *Carpodetus*.

[J. H. B.]

**ESCALLONIA**. A genus of *Escalloniaceæ*, named in honour of a Spanish traveller, the companion and friend of the botanist Mutis. It consists of trees or shrubs, natives of South America, Chili, &c. They have simple leaves, covered with resinous dots; flowers variously arranged, white, pink, or red, with five-parted whorls; and petals and stamens attached to the margin of a cup-like disc which surmounts the ovary. The fruit is a capsule. Several species are in cultivation as greenhouse or half-hardy shrubs. *E. rubra* has tubular red flowers, and is very handsome when trained against a wall. *E. macrantha* is even more beautiful.

[M. T. M.]

**ESCARIOLE**, or **SCAROLE**. (Fr.) *Cichorium Endivia latifolia*.

**ESCENS**. A termination equivalent to the English *ish*; thus, *rubescens* = reddish.

**ESCHERIA**. A synonym of *Salisia*, a genus of gesnerads, of which *Gloxinia maculata* is the type.

**ESCHSCHOLTZIA**. A Californian genus of herbaceous plants belonging to the *Papaveraceæ*, distinguished by its singular calyx, which, unlike that of the true poppies, is lifted off in one piece by the expanding petals instead of separating into two sepals. The petals are four in number, and the seed-vessel resembles the silique of the cruciferous order, being two-valved and bearing the seeds on the edges of the valves. There are several species or varieties, all from California. *E. californica*, the best known, is a large bushy herb with straggling branches, which, as well as the finely divided leaves, are very glaucous. The flowers are large, bright yellow, saffron-coloured in the centre, and expand only in the sunshine. It is a perennial, but in British gardens is mostly treated as an annual, as it flowers the first year and sows itself freely. *E. crocea*, with saffron-coloured flowers, and *E. compacta*, of a less straggling habit, are probably mere varieties.

[O. A. J.]

**ESCHWEILERA**. A genus of Brazilian trees, belonging to the *Lecythidaceæ*, and only differing from *Lecythis* in the limb of the calyx being bent backwards so as to touch the tube.

[M. T. M.]

**ESCOBEDIA**. A genus of *Scrophulariaceæ*, consisting of two South American or Mexican species, erect stiff nearly simple herbs, very rough to the touch, with opposite entire or toothed leaves, and large white flowers, nearly sessile in the upper axils. The calyx is long, tubular, and herbaceous; the corolla-tube very long, with a broad spreading limb; the capsule is two-valved, included in the persistent

calyx. Neither of the species has been as yet introduced into our gardens, although both are said to be handsome. They may, however, possibly be parasitical on the roots of other plants, in which case their cultivation would be very difficult.

**ESCORZONERA.** A Chilean name for *Achyroperus apargioides* and *A. Scorzoneræ*.

**ESENBECKIA.** A genus of arboreal *Rutaceæ* remarkable for their bark, which contains tonic properties. In one of the Brazilian species *cinchonin* has even been detected. The flowers have five-parted whorls, the five stamens ultimately bent downwards, and, like the petals, inserted at the base of a cup-shaped disc, in which the ovary is placed; the latter is warty on the surface, and five-lobed. [M. T. M.]

**ESPADÆA.** The generic name of a Cuban plant said to belong to the *Verbenaceæ*, and to have alternate leaves, and an ovary united half its length with the tube of the calyx. These are characters, however, quite at variance with those of the family. *E. amana* is described by M. Richard as a much branched bush, with rusty down on its twigs, which are furnished with oboval and obtuse smooth leathery leaves, narrowed towards the base; the solitary flowers in the axils of the leaves are stalked, and have a bell-shaped calyx, a funnel-shaped arched corolla, with an oblique border of five erect unequal lobes, and four stamens, two long and two short. The fruits are globose drupes, with two cells, and one seed in each. [A. A. B.]

**ESPAGNOLE.** (Fr.) A kind of olive.

**ESPARCETTE.** (Fr.) *Onobrychis sativa*.

**ESPARTO.** *Lygeum Spartum*; also *Macrochloa tenacissima*.

**ESPATHATE.** Not having a spathe.

**ESPELETTA.** A genus of remarkable *Compositæ*, found near the snow limit at elevations of 13,000 to 14,000 feet and upwards in the Andes of N. Grenada, and Ecuador. A few of them do not exceed a foot in height, and have grassy rigid root-leaves, quite white from a covering of silky hairs. The greater number, however, are taller, and furnished with long strap-shaped root-leaves wholly covered with dense white or rusty-coloured wool, which forms for them an admirable protection from the cold, their thick texture and warm woolly covering no doubt suggesting the name 'Lion's ear' which is sometimes given to them by the Spaniards. The stems terminate either in a single flower-head, or more commonly in a corymb of yellow flower-heads, some an inch or more across.

These plants bear much resemblance to *Culcitium*, which is found in the same regions, and the Spanish appellation 'Fralejon' is common to both. They differ abundantly, however, in having strap-shaped ray florets, and achenes destitute of pappus. About seven species are known. A

resinous substance is present in most of them, but is produced in greatest quantity by *E. grandiflora*; it is of a beautiful yellow colour, and is valued by the printers of Santa Fé de Bogota, who use it in the composition of their ink, and give to it the name of *tremithina* (*terebinthine*), though it has neither the odour nor the consistence of the turpentine of commerce. The genus was named by Mutis in compliment to M. Espeleta, who rendered him much service in his botanical labours about Santa Fé. [A. A. B.]

**ESPRIT D'IVA.** An aromatic liqueur of which *Piarnica moschata* is the basis.

**ESQUINANCIE.** (Fr.) *Asperula cynanchica*.

**ESTERHAZYA.** A genus of *Scrophulariaceæ*, closely allied to *Gerardia*, and differing chiefly in the stamens projecting far beyond the corolla, with the anthers thickly clothed with long woolly hairs. There are two or three species, natives of Southern Brazil, erect branching shrubs or undershrubs, with opposite or scattered entire leaves, and large, very showy flowers of a rich red or pink colour, forming short terminal leafy racemes. Notwithstanding their beauty, they have not been introduced into our gardens, and perhaps, like the *Gerardias*, their cultivation may be very difficult.

**ESTIVATION.** The manner in which the parts are arranged in a flower-bud.

**ESTRAGON.** (Fr.) *Artemisia Dracunculus*.

**ESULE.** (Fr.) *Euphorbia Esula*. — **RONDE.** *Euphorbia Pepius*. — **GRANDE.** *Euphorbia Lathyris*. — **PETITE.** *Euphorbia exigua*.

**ETARIO, ETAIRIUM.** Such a kind of aggregate fruit as that of the *Ranunculus* or strawberry.

**ETERNELLE.** (Fr.) *Helichrysum orientale*.

**ETERNUE.** (Fr.) A kind of *Agrostis*.

**ETHULIA.** A genus of the *Compositæ*, distinguished by the four or five-angled achenes being surmounted by a minute and entire crown-like ring. It is made up of about seven species, all of them branching weeds of no beauty, found in various tropical and subtropical countries of the eastern hemisphere, extending as far west as Syria in Asia, and Senegambia in Africa. The little purple or white flower-heads are numerous, about the size of a small pea, disposed in a corymb at the end of the twigs. [A. A. B.]

**ETIOLATED.** Deprived of colour by being kept in the dark; blanched.

**EUBOTRYE.** A genus of deciduous Ericaceous shrubs, better known under their former name of *Lyonia*. The main characters of the genus are: a five-parted calyx with two small bracts at the base, a more or less cylindrical corolla with a reflexed

limb, ten stamens with short flattened filaments, a truncate stigma, and a five-celled five-valved capsule. The species are handsome North American shrubs, many of them cultivated in this country. The leaves of *E. arborea* have an acid flavour, whence the name of Sorrel-tree. Hunters in the mountains are said to use these leaves as a means of alleviating thirst. [M. T. M.]

**EUBRACHION.** A small kind of leafless mistletoe, growing on myrtles on the river Uruguay, in South America, and constituting a genus of *Loranthaceæ*. It has the male and female flowers mixed in small catkin-like spikes on the terminal branches.

**EUCALYPTUS.** The gigantic Gum-trees, Stringy-barks, and other timbers of the Australian and Tasmanian forests, constitute this genus of *Myrtaceæ*, of which between 100 and 150 species are described, though, owing to the widely different appearances assumed by individual trees at different periods of growth, it is extremely difficult to arrive at a correct estimate of their number. Australia is the headquarters of the genus, numerous species being distributed throughout all parts of that continent; several are also found in Tasmania, where they form extensive forests; and a few extend as far north as Timor and the Molucca Islands. The majority of them are trees, some growing to an immense height and having proportionately thick trunks. Their leaves are of a thick leathery texture, always quite entire, very variable in shape. In young plants they are always opposite, but they generally become alternate as the plant gets older, and their stalks then acquire a peculiar twist, so that the leaves present their edges to the branches. The flowers grow from the angles between the leaves and stem, and are either solitary or in clusters; the calyx is hard and woody, and separates into two pieces, the upper of which resembles a lid or cover, and falls away in a single piece when the flower opens, carrying along with it the corolla, which is intimately combined with it, while the lower is persistent, and bears the very numerous stamens, which form a fringe round its summit. The fruit is closely enveloped in the woody calyx.

The Australian colonists distinguish many of the trees of this genus by characters derived from the bark: some having smooth, others rough or cracked bark; some are solid (iron-bark), while others are fibrous (Stringy-bark); and, finally, in some species the bark scales off in flakes, either from the whole tree or from the upper part only. They are also called Gum-trees, in consequence of the quantity of gum that exudes from their trunks. The timber is exceedingly valuable, and is in common use in our Australian and Tasmanian colonies. In the latter, the three following species yield the best quality of timber, namely: *E. globulus*, the Blue Gum; *E. gigantea*, the Stringy-bark; and *E. amygdalina*, the Peppermint-tree. But of

these the first-mentioned is considered the most valuable, although the Stringy-bark attains the largest size. Trees of the latter species have been felled, measuring upwards of 400 feet high, by 100 feet in girth at a yard from the ground. The blue-gum timber is greatly used by colonial ship-builders, also by mill-wrights, carpenters, and implement-makers, and by engineers in the construction of works requiring beams of great span; it is exceedingly strong and very durable. A plank

*Eucalyptus macrocarpa.*

of the swamp-gum, forwarded to the International Exhibition of 1863, measured 230 feet in length. For some particulars as to the strength of the timber of these Gum trees, see *Gardener's Chronicle*, 1862, 571.

Several species have been introduced to the Negherry hills, and are thriving admirably. Many species yield a red resinous juice, which hardens into a substance resembling kino, and possessing powerful astringent qualities. *E. Gunnii*, the Tasmanian Cider-tree, yields a cool refreshing liquid, from wounds made in its bark during the spring. A saccharine substance, resembling officinal manna, exudes from *E. manuifera*, and other species; *E. piperita* yields an essential oil; and the large flakes of bark obtained from several of the species are used by the aborigines for making huts, canoes, &c. [A. S.]

#### **EUCEPHALUS.** *Diploappus.*

**EUCEREA.** A genus of *Samydaceæ*, nearly related to *Casearia*, from which it may be recognised by its minute greenish-white flowers being disposed in axillary panicles longer than the leaves, not in short axillary fascicles or cymes. *E. nitida*, a Brazilian bush, is the only species. Its spreading branches are furnished with alternate stalked entire leaves, between oval and lance-shaped in form. [A. A. B.]

**EUCHAEDIDIUM.** Two pretty little annuals introduced from California in 1846, belonging to the *Onagraceæ*, and closely allied to *Clarkia*. The genus is distinguished by the long and slender tube of the calyx terminating in four deciduous sepals, by the four three-cleft petals, and by the four-celled, four-valved capsules containing numerous seeds. They grow to the height of about a foot, with somewhat downy stems and foliage; the

leaves are stalked, ovate, and undivided, bearing in their axils solitary purplish flowers. [C. A. J.]

**EUCARIS.** A beautiful genus of broad-leaved evergreen pandaniform *Amaryllidaceæ*, having ovate bulbs, broadly elliptic or ovate long-stalked leaves, and tall scapes bearing several large white nodding fragrant flowers. The blossoms have a long slender tube, six broad ovate spreading perianth segments, and a large bell-shaped white corolla or cup bearing the six stamens on its margin, each having a later tooth at its base. The species are few in number, and are all natives of South America. *E. grandiflora* is one of the most beautiful of stove bulbs. [T. M.]

**EUCHEUMA.** A genus of rose-spored *Algae* belonging to the natural order *Gelidaceæ*, consisting of cartilagino-gelatinous tuberculated or spinous species, remarkable for thick-walled capsules, containing a central placenta, which at length becomes hollow in the middle and bears necklaces of spores. *E. speciosum* is the Jelly-plant of Australia, and is one of the best species for making jelly, size, cement, &c. A very fine species, possessing doubtless similar properties, occurs in the United States. [M. J. B.]

**EUCHILUS.** A genus of much branched Australian under-shrubs of the leguminous family, and usually united with *Pultenaea*, but differing in having a disproportionately large upper lip to the calyx, instead of two nearly equal lips, and a stalked instead of a sessile pod. They have slender twiggy stems, separately or densely clothed with leaves, which are sometimes juniper-like, and sometimes small, round, or inversely heart-shaped; while the little yellow pea-flowers are solitary in the axils of the leaves, and either few, distant, and stalked, or numerous at the ends of the twigs, and nearly sessile. *E. obovatus* is the best known species. [A. A. B.]

**EUCHRESTA.** A genus of *Leguminosæ*, nearly allied to the W. Indian cabbage trees (*Andira*), but differing in having the base of the tubular five-toothed calyx slightly projecting above, and in the standard or upper petal being very narrow, not broad and rounded. *E. Horsfieldii*, the best known species, grows in mountain districts in Java and Formosa, and is an elegant smooth shrub with unequally pinnate leaves; the slender branches terminated by erect racemes of numerous white, waxy, vetch-like flowers, succeeded by stalked elliptical one-seeded pods. According to Dr. Horsfield, the whole plant is intensely bitter, and much sought after by the natives because of its medicinal properties. They employ the seeds against any poison that may have been taken into the stomach, exhibiting one of them triturated with water to counteract the effects. According to Leschenault, the powdered fruits mixed with food are regarded as having the power of preventing diseases and giving tone to the stomach.

Mixed with lemon juice, they are applied to wounds caused by any venomous animal. The fruits are sold for five or even ten sous, French money, each. This plant holds the first rank among the medicinal plants of the island in the opinion of the natives. [A. A. B.]

**EUCLEA.** A genus of simple-leaved African bushes, of the family *Ebenaceæ*, numbering about twenty species. One is found in Abyssinia, another on the west coast south of the line, and the remainder in the southern districts. Their nearest relationship is with *Royena*, from which they are readily distinguished by their flowers being disposed in racemes, not one or three together in the axils of the leaves, and by the males and females growing on different plants. The leaves are alternate or opposite, entire, oval lance-shaped or oblong, sometimes crisped or wavy; and the little white flowers, disposed in racemes shorter than the leaves, are a good deal like those of some whortleberries, having a bell-shaped corolla with five to seven teeth. The fruit is globular, fleshy, and juicy, sometimes as large as a cherry. Those of many of the species, known by the colonists as Guarri, are eaten, and are sweet and slightly astringent. The wood of *E. Pseudo-Ebena*, a species with narrow lance-shaped leaves, is said to be extremely hard and black. [A. A. B.]

**EUCLIDIUM.** A genus of *Cruciferae*, found in South-eastern Europe and Western Asia. It is known from the other genera in which the radicle of the seed is bent round and lies along the edges of the cotyledons, by having a smooth subglobular indehiscent pouch, with a complete partition, and a single seed in each cell. *E. egyptiacum*, the only European species, is a small annual with rigid branches, runcinate root-leaves, and lateral spikes of small white flowers. [J. T. S.]

**EUCNEMIS.** A name given by Lindley to a Mexican Orchid, since referred to *Gonioma*.

**EUCNIDE.** A genus of *Loasaceæ*, now often united with *Mentzelia*, but differing in the tube of the calyx being short and top-shaped; in the numerous stamens collected into five bundles, each of which is attached to one of the five large spreading petals; and in the one-celled fruit opening by five slits at the top, and containing innumerable minute seeds arranged in five rows. *E. bartonioides*, sometimes known as *Micropserpa bartonioides*, a native of Mexico, is a garden annual, with hairy stems, jagged leaves, and large showy sulphur yellow flowers, furnished with very long conspicuous yellow stamens. [T. M.]

**EUCODONIA.** A Mexican generad allied to *Achimenes*, forming a dwarf herb, with ovate obtuse pubescent crenated leaves, and lilac flowers, of which the calyx is deeply five-parted, and the corolla large, ventricose, campanulate with an oblique spreading limb; there are four included stamens, a membranaceous entire glandular ring, and a bilobed stigma. The plant, which is cultivated for the sake of its

flowers, is sometimes called *Scheeria lanata* and *Mandirola lanata*. [T. M.]

**EUCOMIS.** A genus of *Liliaceae*, consisting of South African bulbs, with broad root-leaves, and a simple raceme of rather large usually greenish flowers, surmounted by a tuft of empty leaf-like bracts, called a coma. The perianth is six-parted and spreading, the stamens inserted in its segments, with the filaments dilated at the base. The capsule is three-winged, the few seeds with a hard black seed-coat. Several handsome half-hardy species are in cultivation. *E. bifolia* has only two leaves lying flat on the ground, and a short raceme of pale green flowers. [J. T. S.]

**EUCOSIA carnea** is a terrestrial orchid of Java, with a stem about a span high, bearing four to six ovate leaves, and terminating in a downy spike of about three small flesh-coloured flowers, each supported by a long narrow bract. The plant has the habit of some *Goodyeras*, but the internal structure of the flower is quite different. The remarkable thing is, that the anther is attached to a filament which grows out quite distinctly from the base of the column, whereas in most orchids the anther has no filament, but rests in a niche at the apex of the column. The plant is beautifully represented by Blume in his splendid folio work on the orchids of the Indian Archipelago. [A. A. B.]

**EUCORINUM.** A subgenus of *Fritillaria*, proposed by Nuttall to include a few species which approach to *Lilium*, but differ from both genera, in having an undivided stigma, and the cup formed by the perianth segments broadly funnel-shaped. The habit is that of *Fritillaria*. The *F. tulipifolia* from the Casus, and the American *F. pudica*, to this section. [J. T. S.]

**EUCO.** [A. A genus of stove bulbs of the order *maryliidaceae*. *E. bicolor*, the only species, a native of S. America, has round bulbs, wide petiolated leaves, and a tapering scape, supporting an umbel of four or more vermilion-coloured flowers, which have an oblique perianth tube, compressed recurved limb segments, and a declined cup; abbreviated and rostrate above, and shovel-formed and prolonged below. It comes near *Etheana*. [T. M.]

**EUCYPPHIA.** [A genus placed by most authors in *Hypericaceae*, from which it differs in foliage, in the presence of stipules, and in the albuminous seeds. It was referred by Bentham and Hooker to the *Rosaceae*, and is now placed in *Saufrayaceae* (*Quercoides*) by the former.] The 4-5 leaved calyx is thrown off in the form of a cap; the 4-5 petals are roundish; the stamens numerous and disposed in many series; and the ovary 5-12 celled, surmounted with as many styles. The fruits are little woody capsules. The four known species are opposite-leaved trees or shrubs, two found in Tasmania, and two in Chili. *E. Billardieri* is one of the most beautiful trees of Tasmania, sometimes growing to sixty or a feet high, and covered in February

with an abundance of white cistus-like flowers, one to two inches across. These are solitary and stalked in the axils of the narrow obtuse leaves, which are gummy above, and white underneath. *E. pinnaifolia*, one of the Chilian species, is remarkable in the family, as well as in the genus, for having pinnate leaves, which are made up of two pairs of smooth serrated leaflets, and an odd one; the single white flowers themselves are a good deal like those of a wild dog-rose, and solitary near the ends of the branches. The name *Carpodontos* is sometimes given to the Tasmanian species, which differ from the Chilian ones in having five-celled fruits. [A. A. B.]

**EUCYOLA.** A genus of *Polygonaceae*, allied to *Eriogonum*, having the plicate coloured perianth salver-shaped, the three outer divisions diverging and orbicular, and the three inner linear oblong, forming a cylinder. The flowers are yellow or purple. The species are natives of the Rocky Mountains. [J. T. S.]

**EUDESMIA.** A handsome Swaz River myrtaceous shrub. The branches are four-cornered, with lance-shaped thick leaves; the flowers red, disposed in umbels, with four-parted stamens, united into four bundles; capsule four-celled. *E. tetragona* is in cultivation. [M. T. M.]

**EUDIANTHE.** A section of *Lychitis*, comprising those species which have the calyx tube contracted at the top. The pretty rosy-pink *L. Cadi-rosa*, which is often cultivated as an ornamental annual, under the name of *Viscaria*, belongs to this section. [J. T. S.]

**EUDOXIA.** Peruvian herbs belonging to *Gentianaceae*, with large handsome drooping flowers, in a terminal panicle. They have a bell-shaped membranous calyx; a bell-shaped five-cleft corolla, having the segments convolute before expansion; and the filaments of the stamens are channelled on the inner surface. Ovary two-celled, two-valved; stigma sessile, with two dilated revolute segments. [M. T. M.]

**EUFRAGIA.** A genus separated from *Bartsia* mainly on account of the structure of its seeds, which are 'slightly angular, very minute, crenate-ribbed, the hilum basal.' *E. viscosa*, an erect unbranched annual with viscid foliage and yellow flowers, not uncommon in marshy ground in the west of England and some parts of Ireland and Scotland, is the same as *Bartsia viscosa*. [C. A. J.]

**EUFRAISE.** (Fr.) *Euphrasia officinalis*.

**EUGENIA.** A genus of *Myrtaceae*, comprising several trees or shrubs, for the most part natives of tropical America and the West Indies. The flowers are placed in the axils of the leaves, white, with a four-parted calyx, four petals, and numerous stamens. The berry is crowned by the calyx, one or two-celled, and contains one or two seeds.

The most important species is *E. Pimenta*,

which furnishes Allspice. This consists of the fruits gathered before they are quite ripe, and dried in the sun. The Allspice tree is cultivated in the West Indies and Jamaica, where the trees are planted in rows called pimento walks; the produce is sometimes very large. The Allspice or Pimento berries of commerce are of the size of a small pea, of a dark colour, and surmounted by the remains of the calyx. The odour and flavour are supposed to resemble a combination of those of cinnamon, cloves, and nutmeg, hence the name allspice; they are due to a volatile oil, which is obtained by distillation. Allspice is largely used for flavouring purposes, being cheap. The oil is occasionally employed as a carminative.

Many of the species yield agreeably tasting fruits, such as *E. cauliflora*, which furnishes the Jaboticaba fruits of Brazil, described as being of the size of a green-gage, and very refreshing; it is cultivated in some parts of Brazil. The Rose Apples of the East are the produce of *E. malaccensis* and *E. Jambos*. *E. Ugni*, a native of Chili, has lately been introduced into English gardens, where it is at least as hardy as its near ally, the myrtle. Its fruit is highly esteemed in Chili. Those grown in this country are glossy black when ripe, and have an agreeable flavour and perfume. Numerous other species are grown either for their handsome foliage or for their flowers. *E. Luma* is one of the most beautiful of these. [M. T. M.]

**EUKYLISTA Spruceana**, the only species of the genus, is described as a tree attaining the height of fifty to seventy feet, with bark which scales off like that of the plane tree; its flowers show it to be one of the *Cinchonaceae*. The flower buds are at first enclosed within membranous bracts, which ultimately fall off; the limb of the calyx is scarcely developed; the tube of the corolla is short, its limb divided into six to eight lobes, and its throat lined with dense hairs; stigmas two. Fruit a capsule, dividing into two pieces, the seeds winged. [M. T. M.]

**EULOBUS**. A Californian annual, with narrow leaves, and rather large white flowers often tinged with red, constituting a genus of *Oenotheraceae*, distinguished from *Oenothera* chiefly by its long slender linear capsules incompletely divided into four cells.

**EULOPHIA**. A numerous genus of epiphyllal or terrestrial orchids, natives of tropical Asia, Africa, and America, but occurring in greatest numbers at the Cape. They have either pseudobulbs with one or two leaves, or tuberous rhizomes of the size of potatoes or larger, with the leaves and flower-scapes arising laterally from near the base. The leaves are grassy, or lance-shaped and plaited; and the flower-scapes either simple or branched, bearing few or many flowers, which seldom exceed an inch in diameter, the prevailing colour being yellow. The sepals and petals are nearly equal; the lip pouch or spurred, with an

entire or trilobed limb, bearded or crested in the middle; the column with a terminal helmet-shaped anther-case, enclosing the two pollen masses with their very short caudicle, attached to a rather large diverging gland. A few of the species have been in cultivation. *Cyrtopora*, *Galeandra*, and *Zygopetalum*, have all been referred to this genus by Dr. Blume. [A. A. B.]

**EUMORPHIA**. The name of a pretty little South African bush of the composite family, nearly related to, and having flower-heads like those of the chamomile. It differs, however, in the achenes, which are four or five-angled, and destitute of pappus. The leaves also are very different, being minute, heath-like, and closely packed on the twigs, which are terminated by three white-rayed flower-heads. The plant was first gathered by Mr. Drege, a collector in South Africa, and is named after him *E. Dregeana*. [A. A. B.]

**EUONYMUS**, or Spindle-tree, is a genus of *Celastraceae*, the common species, *E. europæus*, being a familiar shrub or small tree, the wood of which is known as Dogwood, Pegwood, Skewerwood, and Prickwood. It has ovate lanceolate shining leaves, and small pale green flowers, each composed of four petals, issuing cross-wise from a whitish disk. These are borne two to five together on a stalk in the axils of the leaves, and are succeeded by top-shaped seed-vessels of three blunt lobes, and as many cells, each containing a solitary seed. Towards autumn these become more conspicuous among the leaves (now turning yellow) by their assuming a pink hue; and when the tree has entirely lost its foliage, they are highly ornamental. Each of the lobes of the capsule, which has by this time acquired a bright rose-coloured hue, opens at the projecting angle, and discloses the seed wrapped in an orange-coloured arilium. The foliage, flowers, and fruit of the Spindle-tree are poisonous, but the last are sometimes used as a dye. The wood, which is of a light yellow hue, being strong, compact, and easily worked, is applied to many useful purposes. 'Skewers, pegs for shoes, spindles, toothpicks,' readily suggest the derivation of its various names. The charcoal made from the young shoots is also much approved by artists for its smoothness, and the ease with which it may be erased. Among foreign species cultivated in British gardens, *E. latifolius* is the handsomest, from its broad shining leaves and its large red pendulous seed-vessels, with orange-coloured seeds, which, when the capsules open, are highly ornamental. *E. japonicus* is an evergreen species with rounded ovate-toothed leaves. French, *Fusain*; German, *Spindelbaum*.

**EUPATOIRE D'AVICENNE** (Fr.) *Eupatorium cannabinum*. — **DE MÉSUE**. *Achillea Agrostium*.

**EUPATORIUM**. An extensive genus of *Compositæ*, consisting for the most part of

herbaceous plants. The species agree in having all the florets tubular, perfect, and furnished with a long branched style, and in colour either purple, pink, or white, never yellow. They are mostly natives of America; but one species, *E. cannabinum*, Hemp Agrimony, a tall plant with unbranched stems, downy leaves, and terminal crowded corymbs of dull pale purplish flowers, inhabits watery places and damp hedges in Britain. *E. perfoliatum* has some reputation in America as a tonic stimulant, and is administered in the form of a decoction of the leaves; it is employed also as a remedy in intermittent fevers. French *Eupatoire*; German *Adkraud*. [C. A. J.]

The leaves of *E. glutinosum* have been considered to be the Matico of the Peruvians, a substance that is used as a styptic and for other medicinal purposes. It is possible that more than one plant bears the name Matico, but the leaves brought to this country under that name are those of *Arianthe elongata*. [M. T. M.]

**EUPETALUM.** A genus of begoniads, represented by undershrubs found in Peru. The staminate flowers have four, and the pistillate from five to eight sepals. There are four species. The name is derived from two Greek words, *eu* well or good, and *petalon* a petal, in allusion to the character of the sepals. The species were formerly included under *Begonia*. [J. H. B.]

**EUPHORBIACEÆ.** (*Pseudanthææ*, *Trewiaceæ*, *Spurge-worts*.) A natural order of monochlamydeous dicotyledons, typical of Lindley's euphorbial alliance of diclinous Exogens. They are trees, shrubs, or herbs, with opposite or alternate often stipulate leaves, and involucrete incomplete sometimes achlamydeous flowers. Perianth when present inferior, lobed, with glandular scaly or petaloid appendages; stamens definite or indefinite, separate or united in one or more bundles. Ovary one two three or more celled; ovules one or two. Fruit usually of three carpels, which separate in an elastic manner, sometimes fleshy and not opening; seeds with albumen, and often an aril; embryo with a superior radicle. The plants abound in equinoctial America; they are also found in North America, Africa, India, and Europe. They are generally acrid and poisonous, and contain much milky juice. Some yield starch, others oils and caoutchouc. *Euphorbia Lathyris*, the caper spurge, has purgative seeds, and a resinous matter having similar qualities is procured from other species, such as *E. officinarum*, *antiquorum* and *complanata*. Catlimandoo, a kind of caoutchouc, is got from another species in India. Castor oil is procured from *Ricinus communis* seeds; croton oil from those of *Croton Tiglium*. The seeds of *Jatropha Curcas*, or physio-nut, are purgatives. *Sillingsia sebifera* is the tallow tree of China—the fatty matter being procured from the fruit. Dyes are supplied by *Crotophora tinctoria*, the turnsole, and *Rottlera tinctoria*; the latter plant also yields kamila, a powder from its cap-

sule, used for worms. African Oak or Teak is yielded by *Oldfieldia africana*; caoutchouc by *Siphonia elastica*, *lutea*, *brevisfolia*, *brasilensis*, and *Spurceana*; and the poisonous munched by *Hippomane Mancinella*. *Janipha Manihot* or *Manihot utilissima* furnishes cassava and tapioca, which consist of the starchy matter from its root. *Aleurites triloba* yields kekune oil; *Antrophyllum Laurinum* bears an acid fruit called monkey-apple in Sierra Leone. *Colliguaja odorifera* has peculiar jumping or moving seeds, owing to their becoming the habitation of the larva of an insect. Boxwood is the produce of *Buxus sempervirens*. *Hura crepitans*, the sandbox tree, has a fruit consisting of numerous carpels which, when dry, separate with a loud report. Species of *Euphorbia* abound in Africa, and some of them attain a height of thirty or forty feet, with a diameter of two feet at the base of the stem. There are 230 known genera, and about 2,600 species. Examples: *Euphorbia*, *Hura*, *Mercurialis*, *Acalypha*, *Siphonia*, *Jatropha*, *Ricinus*, *Andrachne*, *Xylophylla*, *Phyllanthus*. [J. H. B.]

**EUPHORBIA.** The Spurge genus, which gives its name to the order *Euphorbiaceæ*, comprises a very large number of species distributed throughout almost the whole world, and varying exceedingly in general or outward appearance, but corresponding closely in the structure of the flowers. All have to a greater or less extent a milky juice. In the temperate regions of the northern hemisphere the species are for the most part herbaceous; in warmer countries, especially those of the southern hemisphere, they have a shrubby or even tree-like habit. Many of the South African kinds, as well as those of other countries, possess succulent spiny leafless stems like *Cacti*. Variable as is the appearance of these plants as regards their stems and leaves, their flowers are all arranged on the same plan. The flowers are monocious, collected into heads, surrounded by bracts constituting an involucre; these flower-heads are placed in umbels variously branched or aggregated into clusters round the top of the stem. The involucre is more or less cup-shaped, four or five-toothed, the lobes or teeth alternating with a number of glands of various form. Within the involucre are a number of stamens surrounding a stalked ovary, hence giving the appearance of a single flower; but this is not really so, as each stamen represents a single male flower, because it is jointed in the middle, and has at its base a separate scale. There are really several monandrous male flowers surrounding a central stalked female, which latter consists of a three-celled ovary, with a three-cleft style. The fruit consists of three single-seeded carpels.

A comparatively small number of kinds are cultivated in this country, either for their beauty or as objects of curiosity of the former *E. punicea*, *E. splendens*, *E. fulgens*, *E. prunifolia*, and *E. Bojeri* may be mentioned. These are all remarkable for the brilliant scarlet colour of the bracts,

VEGETATION OF TENERIFFE, WITH SUCCULENT EUPHORBIAS  
(After Webb)

of the involucre, and as they flower in winter time and remain long in bloom, they are deservedly great favourites.

Those cultivated for their singular and grotesque appearance are such as have succulent prickly cactus-like stems, and are for the most part without leaves. Among the best known are *E. grandidens*, a tall-growing kind, sending out whorls of branches like those of a candelabrum; *E. officinarum*, *E. antiquorum*, and *E. canariensis*, all somewhat similar; *E. Hystrix*, which has long spines and lance-shaped leaves at the top part of the stem, the lower portion being destitute of them; and *E. meloformis*, a dwarf species, in shape like a melon or an *Echinocactus*, but without spines. Several of them are so like cactuses that they are frequently mistaken for them, especially as the flowers are comparatively rarely seen; a slight puncture with a pin or the point of a knife will, however, immediately decide the matter, as, should the plant be a *Euphorbia*, a milky fluid will ooze out.

In some districts the succulent Spurges are found in great abundance, as they are able to thrive where little else can grow. Thus in the Canary Islands and Teneriffe *E. canariensis* grows in great abundance in arid rocky districts. Professor Smythe speaks of this plant as attaining a height of ten or more feet, while the branches spread on all sides over twenty feet. The stems are erect, stiff, leafless, prismatic and ill-favoured, 'the product of light and raw bent, salt land, and no shade or genial moisture.' In some parts of South Africa, too, the tall columnar species constitute the characteristic feature of the landscape—*E. grandidens* for one, being said to attain a height of thirty feet and upwards.

The milky juice, which forms one of the constant characteristics of these plants, contains active medicinal properties. Hence in all countries where they grow, some of them have been, or are, employed

them, as they produce incessant sneezing. Euphorbium is an intensely acrid substance, which severely affects the eyes, nose, and lungs of those who come in contact with the drug in its powdered state, if the greatest precautions be not taken. It is said also to induce delirium. From its violent action, it is now rarely if ever used in medicine, but it was employed as an emetic, purgative, etc., and externally as a rubefacient.

The natives of India are said to use the juice of *E. antiquorum* as an external application in rheumatism and neuralgia, and when diluted as a purgative. *E. Nivulia* is used for similar purposes. The juice of *E. heptagona* and other African species is employed by the natives to poison their arrows, while the same purpose is effected in Brazil by the juice of *E. cotinifolia*; that of *E. ligularia* is used in India for the removal of warts; the root, moreover, of the Indian species first named is employed both internally and externally in cases of snake-bite. So also many of the leafy species in which the stem is not fleshy, are considered valuable as purgatives in many parts of the world. Others are esteemed for the cure of syphilis; while some are employed to poison fish. *E. hiberna* is said to have been used in Ireland for this purpose. The roots of some species are emetic, such as those of *E. Gerardiana*, as well as those of *E. Pithyusa* in the south of Europe, and of *E. Ipecacuanha* in America, but they are not to be relied on, as they are apt to produce dangerous purging. Nor are astringent and aromatic properties wanting, for *E. thymifolia*, an Indian plant, has these qualities, as also *E. hypericifolia*, a native of tropical America.

The poisonous principle pervading these plants is more or less dissipated by heat, and hence we hear of a few of them forming articles of diet; thus *E. adula* is mentioned as a pot herb, so also *E. balsamifera*: the juice too of the latter is said when concentrated (by heat) to furnish an

supplying this resinous substance has been recently identified with *E. resinifera*.] *E. canariensis*, *E. officinarum*, *E. antiquorum*, and *E. tetragonum* have all been mentioned. In commerce Euphorbium exists in the form of small irregular yellowish lumps, pierced with one or more holes, in which are often found the remains of the prickles of the stem from which the resin exuded. The drug is procured from Barbary, where the natives are said to make incisions into the branches, in consequence of which the milky juice exudes. This is so acrid, that it scorches the hand when applied to it. The juice is allowed to dry and harden on the stem, and after a time the lumps fall off and are collected with caution, the collectors being obliged, says Mr. Jackson in his account of Morocco, to tie a cloth over their mouth and nostrils, to prevent the small dusty particles from annoying

In the habit of removing the bark from *E. canariensis*, and then sucking the inner portion of the stem, in order to quench their thirst. This is indeed not so improbable as at first appears, as it is the limpid watery ascending sap which is taken, while the acrid milky descending sap is removed with the rind of the tree, which it percolates. The juice of *E. Cattimandoo*, a native of the Madras presidency, furnishes caoutchouc of a quality which is such as to enable it to be put to a variety of uses; some of it was favourably reported on in the Jury Reports of the Great Exhibition of 1851. Dr. Wight, in his *Jones Plantarum Indiae orientalis*, gives the following information on the authority of Mr. Elliot:—'The milk is obtained by cutting off the branches, when it flows freely. It is collected and boiled on the spot, at which time it is very elastic, but after being formed into cakes or cylinders, it becomes

resinous or brittle, in which state it is sold in the bazaars, and employed as a cement for fixing knives into handles, and other similar purposes, which are effected by heating it. It is also employed medicinally as an outward application in cases of rheumatism. The gum has not the valuable property, like gutta percha, of being ductile at all times. It can be moulded to any shape when first boiled, but as far as we know not afterwards, though some plan may be found for rendering it subsequently pliable. Dr. Wight further remarks that when exposed to the heat of a fire or lamp it rapidly softens, and becomes as adhesive to the hand as shoemaker's wax, but when soaked for some time in warm water, it slowly softens, becomes pliable and plastic, and in that state takes any required form. Another of the Indian species, *E. Thucalli*, is frequently used in Coromandel, for making hedges, as animals for the most part will not touch it, though goats will eat it in spite of the acrid juice, which latter is used medicinally by the natives. It goes by the name of Milk Hedge. *E. phosphorea* derives the name from the fact of its sap emitting a phosphorescent light on a warm night in the Brazilian forests. There are several British species, which partake more or less of the acrid properties so general in this group. [M. T. M.]

**EUPHORBIALES.** One of Lindley's alliances, including *Euphorbiaceæ*, and a few small related groups.

**EUPHORIUM.** A gum resin obtained from certain succulent species of *Euphorbia*, especially *E. resinifera*.

**EUPHRASIA.** The Eye-bright is a small annual belonging to the *Scrophulariaceæ*, distinguished by a tubular four-cleft calyx, a two-lipped corolla, the upper lip two-lobed, the lower three-lobed, and an oblong compressed capsule, containing numerous pendulous ribbed seeds. Eye-bright is a common plant in heaths and dry meadows, growing to the height of six to twelve inches, with small sessile leaves arranged in opposite pairs, and several flowers near the ends of the branches, white spotted with yellow and purple. From the frequent mention of Euphrasy by the poets, it would appear to have been formerly held in high repute for its medicinal virtues, a view which is confirmed by the statements of the old herbalists, who recommended its use both outwardly and inwardly, in powder and in decoction, for complaints of the eyes. It is still a rustic remedy as an eye-water, but is said by some to be injurious rather than beneficial. French, *Eupraise*; German, *Augen-trost*. [C. A. J.]

**EUPHROSINE.** A genus of *Compositæ*, composed of two annual Mexican weeds, which grow from one to two feet high, and have alternate twice or thrice pinnatisect leaves, and terminal panicles of little white flower-heads, each about the size of a pea. The flowers have much re-

semblance to *Ambrosia*, but differ in having male and female flowers in the same capitulum. [A. A. B.]

**EUPLOCA.** A North American genus of *Ehretiaceæ*, probably not distinct from *Messerschmidia*, and consisting of herbs furnished with rough leaves, and funnel-shaped flowers. [J. T. S.]

**EUPOMATIA.** A genus of laurel-like shrubs, natives of the eastern extratropical parts of New Holland. It forms at present a kind of botanical puzzle, being evidently allied to *Anonaceæ*, and yet differing very materially from the other genera of that family. *E. laurifolia* was discovered by the late Robert Brown, and though it is cultivated in conservatories, it has not produced its flowers. The stamens are perigynous, and the inner ones sterile, petal-like; the tube of the calyx is coherent with the ovaries, while the limb separates by a transverse slit, like a lid, from the tube. In these flowers the access of the pollen to the stigmas appears to be completely cut off by the number and disposition of the internal barren petal-like stamens; but the communication is restored, says the learned botanist who first described the plant, by certain minute insects eating the petal-like filaments, while the antheriferous stamens, which are either expanded or reflected, and appear to be even slightly irritable, remain untouched. Recently a second species has been discovered, and named by Dr. Mueller *E. Bennettii*, in compliment to Dr. Bennett, the well-known Australian naturalist. This species has produced flowers in this country, and is figured in the *Botanical Magazine* (t. 4348), under the name of *E. laurina*, its distinctness from that species not having been at first detected. [M. T. M.]

**EUPTERIS.** A sectional name applied by Agardh to the normal forms of *Pteris*, as distinguished from the groups represented by *P. aquilina* and *Litobrochia vesperilionis*. It is applied by Newman as a generic name to the common Bracken, *Pteris aquilina*.

**EUROTIA.** A genus of *Chenopodiaceæ*, found in Russia and Siberia, and consisting of annuals with numerous branches, narrow entire leaves, and male flowers four or five together at the apices of small branches. The female flowers are solitary in the axils of the leaves, with the fruiting perianth limb growing out in the shape of two horns. [J. T. S.]

**EURYA.** A genus of *Ternstroemiaceæ*, composed of a number of evergreen shrubs or small trees found in India, China, and the adjacent islands, one species extending to the Feejee Islands. Their very minute and unisexual flowers, together with their small berried fruits, serve to distinguish them. The leaves are not unlike those of the tea plant, and the small white flowers are arranged in bundles in their axils. [A. A. B.]

**EURYALE.** Before the discovery of the *Victoria regia*, the Indian aquatic herb bearing the above name took rank, perhaps, as the noblest aquatic plant in cultivation, at least as to its leaves, which are much like those of the *Victoria*, but smaller, of a circular form, with very prominent and spiny veins on the rich purple under-surface: the upper surface being covered with rounded eminences, and of a dark green colour; and the size varying from one to four feet in diameter. The flowers are stalked, and have a calyx which is adherent below to the ovary, but above it is divided into four segments; the whole outer surface of this calyx is covered with strong spines; the petals are from twenty to thirty, smaller than the calyx, and of a purple colour; the stamens numerous, detached, all fertile. Fruit a round many-seeded berry, crowned by the persistent calyx. By these characters *Euryale* is distinguished from *Victoria*: both belong to the *Nymphæaceæ*. *E. ferox* is a native of the eastern part of Bengal and other quarters of India, where also it is frequently cultivated. Its seeds are starchy, and after being baked in sand are eaten by the natives. The Hindoo physicians, moreover, say that they possess medicinal virtues. The plant is also grown in China for the sake of its seeds. [M. T. M.]

**EURYBIA.** A genus of trees or shrubs of the composite family, confined to Australia, Tasmania, and New Zealand, and numbering upwards of sixty species. In many respects it is allied to *Aster* of the northern hemisphere, but the flower-heads do not contain nearly so many florets. The genus *Olearia* is their closest relationship, but there the pappus is double, while here it is single. They are very variable in appearance, some being large trees, others heath-like shrubs; and the daisy-like flower-heads are either solitary or numerous and panicled at the ends of the branches.

The silver-leaved Musk tree, *E. argophylla*, is a Tasmanian plant, attaining a height of twenty to twenty-five feet, with a girth of three feet. It is often seen in greenhouses as a shrub, where it is cultivated for the musky odour of its leaves. The wood of the tree is hard and takes a good polish. The larger-leaved species, which are chiefly confined to New Zealand and Tasmania, are much like this in appearance. The smaller-leaved ones are more common on the continent. Amongst these latter is *E. Dampieri*, found in great abundance by Dampier on one of the islands on the north-west coast, which now bears his name, and called by him Rosemary, from its resemblance to that plant. The name Daisy-tree is given to *E. hrata* in Tasmania. The name of the genus is that of the mother of the stars in Greek mythology. [A. A. B.]

**EURYCLES.** A genus of amaryllids, of the pancratiform group, found in the Eastern Archipelago and in New Holland. The bulbs are ovate; the leaves are broad and petiolated; and the scape, which

scarcely precedes the leaves, supports a many-flowered umbel of flowers, of which the tube is cylindrical, the limb regular, with equal segments, and the cup frequently imperfect. *E. amboinensis* is a stove bulb. *E. australasica*, or *Cunninghami*, a smaller species from Australia, is called the Brisbane Lily. [T. M.]

**EURYCOOMA.** A genus of shrubs from Sumatra, referred by Planchon to the *Simarubaceæ*. The leaves are compound, and clustered at the extremity of the branches; the flowers are panicled, of a purple colour, and on some plants unisexual, on others perfect. *E. longifolia* is stated to be a valuable febrifuge. [M. T. M.]

**EURYLOBIUM.** A genus of *Stilbaceæ*, a family of corollifloral dicotyledons, consisting of shrubs furnished with rough linear leaves; and terminal spicate white flowers of which the calyx is five-toothed, the corolla tubular, five-cleft, its two upper lobes larger and connate, the tube hairy within, and the stamens four in number. *E. latum*, the only species which is known, is a native of South Africa. [J. H. B.]

**EURYNEMA.** A small annual Arabian plant belonging to the *Eygophyllaceæ*. The flowers are on long stalks, which are bent in the middle; stamens five, their filaments dilated at the base, shorter than the anthers; ovary on a short stalk, with several ovules in each of its five compartments. Fruit capsular. [M. T. M.]

**EURYOPS.** A genus of *Compositæ*, nearly allied to *Senecio*, but differing in the nature of the involucre, which is composed of one series of scales having their margins more or less united, so that the involucre has the appearance of a toothed cup; while in *Senecio* the scales are free. The hairs of the short woolly pappus are curiously bent in a zig-zag manner, and their outer row is often deflexed. Of about thirty known species, one is found in Arabia, another in Abyssinia, and the remainder in S. Africa. They are handsome often resinous under-shrubs, very variable in appearance, some having the leaves smooth undivided pine-like, while in others they are wedge-shaped and toothed, and in a goodly number are pinnately-lobed and cut. The yellow-rayed flower-heads are small disposed in corymba, or large and solitary. *E. spaciostictus* is called Roebush by the colonists, because of a gummy exudation often seen on the stem and leaves. The handsome flower-heads are nearly four inches across. [A. A. B.]

**EUSCAPHIS** *staphyleoides* represents a genus of *Staphyleaceæ*, found in Japan, the Corea, and the Loo Choo islands. It resembles the common *Staphylea pinnata*, but it is easily recognised by its fruits, which are composed of three distinct bladderly carpels; while in *Staphylea* the carpels are united so as to form one bladderly capsule. The plant grows to a bush of about twelve feet high, and is furnished with opposite pinnate smooth leaves, which

are a good deal like those of the elder; and so also are the little white or yellowish flowers, which are numerous and disposed in terminal panicles. According to Siebold, the plant is a favourite in Japanese gardens from its neat habit and its pretty bladdery fruits, which are of a red colour when ripe, and remain on the bush till winter approaches. It is prized also for its medical properties. The inner bark of the root is bitter and astringent, and is given in infusion in cases of dysentery and chronic diarrhoea. The leaves are not so efficacious, and have when fresh a disagreeable fishy smell. The name of the genus has reference to the pretty fruits, which open along the inner surface into the form of a little boat. [A. A. B.]

**EUSTACHYS.** A genus of grasses belonging to the tribe *Chlorideæ*; now included in *Chloris*. [D. M.]

**EUSTEGIA.** A genus of South African *Asclepiadaceæ*, containing a few species of decumbent branching perennial herbs, with opposite hastate leaves, and sub-umbellate flowers, the calyx of which is five-parted, and the corolla rotate and five-cleft, with a triple staminal crown: the divisions of the two inner whorls of the latter alternating with the lobes of the outer whorl and with the anthers. [W. C.]

**EUSTIGMA oblongifolium.** A small tree of Hong Kong, forming a genus of *Rhamnideæ*, distinguished chiefly by its long broad flat stigmas. The flowers are in small loose bruds, without any petals, except five small gland-like scales, and have five stamens, with obtuse two-valved anthers, and a half-inferior ovary.

**EUSTOMA.** A gentianaceous annual plant, native of North America, the flowers of which are white, with a deeply five-cleft calyx, a funnel-shaped corolla, with a contracted tube into the middle of which the stamens are inserted, and a large two-lobed stigma. [M. T. M.]

**EUSTREPHIS.** A genus of *Liliaceæ*, consisting of twining woody-stemmed plants, from the warmer parts of Australia, with elliptical or lanceolate leaves, and aggregate, pedicellate flowers, from the axils of the leaves and the end of the stem. The flowers are purplish, with a six-parted spreading perianth, the inner divisions fringed. [J. T. B.]

**EUTASSA.** A genus of coniferous plants, sometimes considered as a section of *Araucaria*, and including those species which have been called needle-leaved, such as *A. excelsa*, *Cunninghami*, and *Cookii*. [See *ARAUCARIA*.] The species included under *Eutassa* are found in Australia, as at Norfolk Island, Moreton Bay, New Holland, and New Caledonia. As a sub-genus of *Araucaria*, sometimes called *Eulacta*, it is thus defined: scales of the cone broadly winged; a distinct basal appendage to the seed: anthers six to ten-celled; cotyledons four. [J. H. B.]

**EUTAXIA.** A genus of pretty leguminous bushes found in Australia, but chiefly confined to the western portions, and comprising about eight species. They have much the appearance of *Pultenaea* or *Dalrymplea*, so well known as greenhouse plants, and differ from the former in the standard being about as broad as it is long, not broader; from the latter in the wings being shorter than the keel, not equal to it in length; and from both in having opposite leaves. They are for the most part much-branched low-growing bushes, with small often peath-like leaves, and axillary golden-yellow pea-flowers, two or three together. *E. myrtifolia* is a well-known greenhouse plant, whose slender stems are often seen thickly covered in the spring and summer months with the pretty yellow blossoms. [A. A. B.]

**EUTERPE.** A genus of palms of extremely graceful habit, having slender almost cylindrical stems, sometimes nearly a hundred feet in height, surmounted by a tuft of pinnate leaves, the leaflets of which are narrow, very regular and close together, and generally hang downwards. The bases of the leaf-stalks are dilated, and form cylindrical sheaths round a considerable portion of the upper part of the stem, giving it a woollen appearance. Ten species are known, all natives of the forests of tropical South America, where they grow together in large masses; some inhabiting moist swampy places on the banks of rivers, and others extending a considerable height up the sides of mountains. Their flower-spikes, which grow out horizontally from the stem below the swelling of the leaf-stalks, are simply branched, and the flowers are seated in little furrows upon the branches, with bracts at their base: the males and females being in pairs on the lower parts of the branches, while the males are most numerous on the upper parts. The fruits are of a dark purple colour, with a thin fibrous fleshy rind, enclosing a single seed.

*E. edulis*, the Assai Palm of Pará, grows in swampy places, particularly upon the banks of rivers within the tidal limits, where it attains a height of thirty or forty feet, and has a stem about as thick as a man's arm, slightly bulged out at the base, and generally curved or leaning over. Its fruit, which resembles a date in size and colour, has a thin coating of clotted fibrous flesh, from which the inhabitants of Pará manufacture a beverage called Assai. This is prepared by throwing the ripe fruits into a vessel containing warm water, and allowing them to soak for about an hour, and then, the water being partly poured off, kneading them thoroughly with the hands, fresh cold water being occasionally added, until all the pulp is detached, when the liquid is separated by straining, and is then fit for use. It is of a thick creamy consistence, and of a fine plum colour; and when sweetened with sugar, and thickened with cassava farina, it is very nutritious, and forms the greater part of the daily food of

a large number of the inhabitants of Paris, with whom Assai is a great favourite.

*E. montana*, a West Indian species, is cultivated in the hothouses of this country. It attains a height of about twenty feet, and has the base of its stem much swollen or bulged out. The central portion of the upper part of the stem, including the leaf-bud, of this and the other species is eaten either when cooked as a vegetable or pickled; but the tree must be destroyed in order to obtain it. [A. S.]

**EUTHALES.** A goodeniaceous genus, native of the south-west coast of Australia. It bears a tubular unequally five-cleft inferior calyx, a corolla cleft on one side at the apex with a bilabiate limb, free anthers, an undivided style, with the indusium of the stigma bilabiate, and a four-valved capsule. They are stemless herbs with long-stalked nearly entire leaves, and yellow flowers. [R. H.]

**EUTHEMIS.** A genus placed by some authors in *Sauvageanaceae*, and by others in *Ochnaceae*; differing from any in the former in its berried fruit, and from any in the latter in the fruit being composed of five united carpels, instead of numerous free carpels seated on a rounded and thickened receptacle. It is composed of a few beautiful little shrubs of the Malayan Archipelago, having smooth rounded stems furnished with alternate, elliptical or lance-shaped leaves beautifully and minutely serrulate at the margins, and the glossy blades exquisitely marked with a great abundance of parallel nerves running at right angles to the midrib, the spaces between them forming a beautiful network of veinlets. The flowers are white or tinged with purple, and disposed in axillary or terminal compound racemes. [A. A. B.]

**EUTHYSTACHYS.** A genus of *Subbaceae*, entirely confined to S. Africa, and differing from its nearest ally, *Campylostachys*, in its straight, not curved, flower-spikes, whence the name of the genus, and in the little funnel-shaped corollas, which have a five-lobed instead of a four-lobed border. The only known species, *E. abbreviata*, is a smooth shrub, with henth-like four-ranked leaves thickly set on the stems, which terminate in a bracted spike of flowers. From the other genera this differs in having a calyx two of whose narrow segments are free, and three are united by their margins nearly to the summit. [A. A. B.]

**EUTOCA.** Annual herbs belonging to the *Hydrophyllaceae*, of an erect habit, with rough leaves, and clusters of showy flowers. They are natives of North America, especially California, and are often grown in European gardens. The species mostly cultivated are *E. Menziesii* or *multiflora*, about eighteen inches high, with downy narrow leaves, either entire or lobed, and blue flowers. *E. viscidula* is much branched, with heart-shaped deeply-cut toothed clammy leaves, and elongated racemes of blue flowers with a rose-coloured tube.

All the species are elegant and hardy. French, *Eutoqua* [C. A. J.]

**EUTRIANA.** A genus of grasses belonging to the tribe *Chlorideae*. The inflorescence is for the most part in short racemose spikes; spikelets one-sided, alternately sessile, two to three-flowered; glumes two, keeled, the exterior larger; palea two, of thickish texture, the inferior one three-cleft, the superior two-keeled. The score of known species are nearly all natives of South America. [D. M.]

**EUTROPIS.** An imperfectly described genus of *Asclepiadaceae*, containing a single species, abundant in the Punjab, and forming a low twining fleshy lance-leaved undershrub. Its position is between *Calotropis* and *Paratropis*, having the angular and saccate sinuose corolla, membranaceous-lipped anthers and corona of the former; and the coronal leaflets cleft, and the pollen masses oval and ventricose, as in the latter. [W. O.]

**EUXENIA.** A genus of opposite-leaved Chilian shrubs belonging to the composite family, and distinguished amongst its allies by each yellow flower-head being entirely composed of unisexual florets, all of which are tubular and five-toothed. The leaves, somewhat rough to the touch, are broadly oval or lance-shaped; and the globose yellow flower-heads usually grow two or three together, and are stalked at the ends of the twigs, and about half an inch across; the achenes are four-sided, without pappus. There are but two species. *E. grata*, with broadly oval leaves, is called by the Chilians Palo Negro; the other, *E. Matiqui*, with lance-shaped leaves, is called Matiqui. In both the leaves have a pleasant aromatic scent. [A. A. B.]

**EVANESCENTI-VEBOSE.** When lateral veins disappear within the margin.

**EVAX.** A genus of *Compositae*, found in the Mediterranean region and in California, and composed of a few minute tufted annual herbs, having all their parts clothed with white wool like many of the cudweeds. In some species, as in *E. eriophora*, the whole plant does not exceed a quarter of an inch in diameter, and looks like a little ball of wool, whence the specific name. None of them exceed four inches in height, and it branched the branches are not more than two inches long, and terminate in a sessile flower-head surrounded by a rosette of oblong woolly leaves. The genus is chiefly distinguished among its allies by the elongated cone-shaped receptacle on which the florets are seated, and by the achenes being destitute of pappus. [A. A. B.]

**EVELYNA.** A numerous genus of South American epiphytal orchids, found growing on stems and trunks of trees, and readily known by their habit. They have erect wiry stems, one to three feet high, furnished with lance-shaped strongly ribbed leaves, and terminating in a few-flowered spike, the flowers enveloped by

long coloured bracts. The anther is two-lobed, with eight pollen masses attached in fours to a very short caudicle with a triangular gland. *E. Caravata*, from the West Indies and French Guiana, is in cultivation. It has hispid stems a foot high, bearing long lance-shaped rough leaves, and bright yellow flowers with a beautifully fringed lip, almost hidden from view by long pink bracts. The genus bears the name of John Evelyn, an eminent patriot of the seventeenth century. *Elleanthus* is a synonym. [A. A. B.]

**EVENING FLOWER.** *Hesperantha*.

**EVENNESS.** An absence of elevations or depressions of the surface of any part or organ.

**EVERGREEN.** Continuing to bear green leaves all the year round.

**EVERNIA.** A small genus of lichens belonging to the usneoid tribe of *Parmeliaceae*, differing from *Ramalina* in their having a distinct under-surface to the flat erect branched fronds. They are sometimes prettily coloured, *E. favicans* and *vulpina* being of a beautiful yellow. *E. prunastri* is common in almost every thicket, and was formerly ground down with starch to make hair powder. It was used, at the instigation of Lord Dundonald, as a substitute for gun in cotton-printing. The yellow species contain two distinct colouring principles, and of these *E. vulpina* is said to be poisonous to wolves. *E. favicans* occurs in the south of England, but prefers warmer regions. [M. J. B.]

**EVIA.** A genus of Indian trees belonging to the *Anacardiaceae*, and, judging from description, so closely allied to *Spondias* as hardly to be distinguished from it. In *Evia* the filaments are awl-shaped, in *Spondias* thread-like. The fruits of *Evia* are edible. [M. T. M.]

**EVITATE.** Not striped; destitute of vittae.

**EVODIA.** A genus of small rutaceous trees or shrubs, natives of tropical New Holland and the Indian Archipelago. The flowers are disposed in a paniced manner, and the flower-stalks are jointed in the middle. The parts of the flower are four-fold; the calyx persistent; the petals and stamens inserted at the base of a cup-shaped sinuous disc, which encircles the lower part of the four ovaries; the styles are four, becoming after a time fused into one. The fruit consists of four carpels which separate. *E. triphylla* is a stove-shrub with white flowers. [M. T. M.]

**EVODIANTEUS.** A genus of Pandaceae, consisting of climbing somewhat palm-like plants, with cleft leaves, and monocious flowers arranged on stalked spadices, which are protected by three bracts. The perianth of the male flower, in which the distinguishing characters of the genus reside, is tubular, funnel-shaped and curved, the lower portion fleshy and triangular, the upper part bell-shaped, some-

what four-cornered, the limb very short and divided into several lobes, which are arranged in two rows, those of the outer row detached one from the other, those of the inner confluent, and provided with two teeth. The species are natives of Costa Rica, and greatly resemble those of *Carludovica*. [M. T. M.]

**EVOLUTIO.** The act of development.

**EVOLVULUS.** A considerable genus of *Convolvulaceae*, containing nearly sixty described species, natives chiefly of tropical America, but with one or two species from the warmer regions of the Old World. They are annual herbs, or have a perennial sometimes woody stock, and bear entire usually small nearly sessile leaves, and small flowers on axillary peduncles, or in terminal spikes or racemes, with the corolla campanulate or funnel-shaped, and angular or lobed. [W. C.]

**EVONYMUS.** *Euonymus*.

**EVOSMIA.** Tropical American shrubs or small trees, belonging to the *Cinchonaceae*, and having red flowers on slender axillary stalks, the corolla wheel-shaped, the stamens short. The fruit is a four-celled berry, crowned by the limb of the calyx, and having an agreeable odour. Sir R. Schomburgk says that cases of poisoning among the Indians have arisen from their using the wood of one of these plants, *E. corymbosa*, as a spit whereon to cook meat. [M. T. M.]

**EWALDIA.** A genus of begoniads, consisting of villous shrubby plants found in Brazil. Their staminate flowers have four, and the pistillate five sepals; anthers oblong, with united filaments; style persistent, its branches surrounded by a continuous papillose band, which makes two spiral turns; placentas undivided, their transverse sections being ovate. There are two known species, *E. ferruginea* and *E. lobata*; both of them formerly included under *Begonia*. The genus is named in honour of Dr. Ewald, of the Berlin Academy. [J. H. B.]

**EX.** See *E*. But *exo* signifies outwards or external, as in *exogens* and *exintine*, quasi exintine.

**EXACUM.** Erect branched annual herbs, with opposite sessile leaves and showy, blue, yellow, or white flowers, belonging to the *Gentianaceae*. The calyx is bell-shaped and four-cleft; the corolla salver-shaped, four-cleft, with an inflated tube; the capsule globose, two-celled, many-seeded, and splitting; the seeds minute. The plant described by Sir J. Smith under the name of *Exacum filiforme* is the *Gentiana filiformis* of Linnaeus and the *Oicentia filiformis* of modern botanists. French, *Gentianello*; German, *Kugelröhre*. [O. A. J.]

**EXADENUS.** Tropical American annuals of the gentian family, with linear leaves and four-parted flowers, the corolla wheel-shaped, four-cleft, persistent, and each of its four segments provided on the outside

near the base with a sessile or stalked gland; capsule two-seeded. [M. T. M.]

**EXALBUMINOSE.** Having no albumen.

**EXANTHEMATA.** Skin diseases, blotches of leaves, &c.

**EXAREOLATE.** Not spaced out.

**EXARISTATE.** Destitute of an arista, awn, or beard.

**EXASPERATE.** Covered with hard short stiff points.

**EXCENTRIC.** Out of the centre.

**EXCIPULE.** That part of the thallus of a lichen which forms a rim and base to the shield. Also a similar part in certain fungi.

**EXOCOCARIA.** A small genus of spurge-woods consisting of about eighteen species, five or six of which belong to India, while the remainder are natives of the West Indies and Brazil. Most of them are woody shrubs, but a few form small trees. Their leaves are usually alternate, and either entire or with their margins toothed. The flowers are produced in catkins, some species having the males and females on distinct trees, and others bearing them in different parts of the same catkin. The individual flowers have neither calyx nor corolla, but their place is occupied by a variable number of little bracts. The fruit is three-celled.

*E. Agallochum* was at one time supposed to yield the fragrant resinous Indian wood called Agallochum, Aloes or Eagle wood, which is now, however, known to be the produce of *Aquilaria Agallochum*, a plant belonging to a totally different natural order. It is a native of India, where it is commonly found growing in salt marshes, and is sometimes employed for strengthening the banks of rivers in places within the influence of the sea water. It forms a small crooked tree or large branching shrub, with egg-shaped leaves, having round blunt teeth along their edges. The different sexes of the flowers are borne on distinct trees, the male catkins being very long, and either solitary or in pairs, while the females are much shorter, and sometimes three together. When the tree is wounded, a white milky juice flows from it, which is of a very acrid nature, producing inflammation and ulceration if allowed to come in contact with the skin. If it gets into the eyes it causes blindness. The wood is used for charcoal and firewood, but the smoke from it is said to cause intolerable pain in the eyes. [A. S.]

*Gussonia* of Sprengel from Brazil, and *Gymnanthes* of Swartz from the W. Indies, both monœcious, are included by modern authors in the present genus.

**EXCRETION.** Any superfluous matter thrown off by the living plant externally.

**EXCURRENT.** Running out. When a stem remains always central, all the

other parts being regularly disposed round it, as in the stem of a fir tree.

**EXEMBRYONATE.** A name given to cryptogams in consequence of their spores not containing an embryo like the seeds of phanogams. Though, however, the spores contain no embryo in the higher cryptogams, the archegonia contain a cell which goes through the same process of cell-division as the embryonic cell in phanogams, sometimes producing a distinct plant, sometimes only fruit. [M. J. B.]

**EXILE.** *Theselia nerifolia*.

**EXINDUSIATE.** Without an indusium.

**EXINTINE.** The middle coat of a pollen grain, or if three or four coatings are present, then that next the intine.

**EXOCARPUS.** A genus of *Thymelaceæ* or *Daphnaceæ*, though some refer it to a separate order, *Anthoboleæ*. The flowers are sometimes perfect, at other times incomplete. The perianth is four to five-parted; stamens four to five, inserted on the base of the perianth, the filaments short; ovary free, one-celled; the style very short, and the stigma capitate. Fruit, a single-seeded nut, supported on an enlarged bearded peduncle. Trees and shrubs of New Holland; found also sparingly at the Moluccas. They have scattered, often minute, leaves, which have no stipules; flowers small in axillary spikes, with caducous bracts, the flow or stalk enlarging after fertilisation. There are four known species. [J. H. B.]

**EXOCHORDA.** A beautiful Chinese bush of the rose family, cultivated in England and quite hardy. It is remarkable for the structure of its fruits, which consist of five small compressed bony carpels adhering round a central axis in a star-like manner. From the axis or growing point stand five erect placental cords, which enter the carpels on their inner face near the top, suspending from the apex two thin seeds. These cords remain after the carpels have fallen, and have suggested the name of the genus. The only species, *E. grandiflora*, is a smooth bush with alternate nearly lance-shaped entire leaves, the stems terminated by racemes of handsome white flowers, which appear in May, and are nearly as large as those of the mock-orange; they have a bell-shaped calyx with a five-parted border, five rounded petals, and fifteen to twenty stamens. The plant bears also the name of *Spiræa grandiflora*. [A. A. B.]

**EXOGENS.** A name given to one of the great classes of the vegetable kingdom, corresponding with the Dicotyledons. The name Exogen is derived from the Greek words signifying 'outwards' and 'to grow,' meaning growing outwardly, and has reference to the mode in which the woody circles are produced, viz. from the centre outwardly towards the circumference. The age of an exogenous tree, particularly in temperate climates, may be

determined by counting the number of zones or circles in the woody stem, each circle marking one year's growth, and the last-formed circle being external. All the native trees of Britain are exogenous. The characters of the class are given under the head DICOTYLEDONS. [J. H. B.]

**EXOGENOUS.** Growing by addition to the outer parts of the stem.

**EXOGONIUM.** A genus of *Convolvulaceæ* very closely allied to *Convolvulus* and *Ipomœa*, from both which it is distinguished by its stamens projecting from the tube of the corolla; and from the former by its button-like stigma. *E. Purga*, a Mexican climbing plant, with salver-shaped purplish flowers, furnishes the true Jalap tubers of commerce. These are roundish, of variable size, the largest

*Exogonium Purga.*

being about as large as an orange, and of a dark colour. They owe their well known purgative properties to their resinous ingredients, and hence worm-eaten tubers are more valued than sound ones, as the insects eat the farinaceous and woody portions of the tuber and leave the resin. Various species of *Ipomœa* are also said to furnish a spurious kind of Jalap. [M. T. M.]

**EXORHIZE.** A name given to exogenous or dicotyledonous plants, from the mode in which the young root sprouts when the seed is placed in the ground. The term is derived from the Greek *exo* outwardly, and *rhiza* a root, meaning root pushing outwardly, in allusion to it pushing out directly in a tapering manner, and not coming out in the form of numerous rootlets through sheaths as in the *Endorhize*, or monocotyledons. [J. H. B.]

**EXORHIZAL.** That kind of germination in which the point of the radicle itself becomes the first root.

**EXOSMOSE.** That force which causes a viscid fluid lying on the outside of an

organic membrane to attract watery fluid through it.

**EXOSTEMMA.** A genus of tropical trees or shrubs of the *Cinchona* family. They have whitish or pink flowers of a funnel-like form, the segments of the limb linear and rolled back; the five stamens project to a considerable distance from the corolla, hence the name of the genus. The ovary is two-celled, with a long style, and almost undivided stigma; capsule two-seeded: some of the kinds are in cultivation. The barks of the West Indian species possess febrifugal qualities, as in the closely allied *Cinchona*. [M. T. M.]

**EXOSTOME.** The aperture in the outer integument of an ovule.

**EXOSTOSIS.** A name given to a diseased condition in plants, in which hard masses of wood are produced, projecting like warts or tumours from the main stem or roots. Most cases seem to arise from tissues developed round adventitious buds which do not properly break through the bark. These are sometimes completely concealed, as the knurs in beech, which are often quite free. Sometimes there is a continued multiplication of fresh buds, and in proportion as these are more or less developed, we have the besom-like bodies on birch, or the rough tumours on elms. Cypress knees, which sometimes grow to a great size, and when hollowed are used for beehives in the United States, grow by a similar disease on the roots of *Taxodium*. Fine specimens may be seen at Sion. The tumour at the junction of a graft with its stock seems to arise from some different cause, which is not at present ascertained. [M. J. B.]

**EXSERTED.** Projecting beyond the outline of an organ.

**EXSUCCOUS.** Juiceless.

**EXTINE.** The outer coat of a pollen grain.

**EXTRA.** On the outside of, or beyond; as *Extra-axillaris*, beyond the axil; *Extra-foliaris*, beyond a leaf; *Extra-medianus*, beyond the middle.

**EXTORSE.** Turned outwards from the axis of growth of the series of organs to which it belongs.

**EYE.** A term in gardening for a leaf-bud; also for the centre or the central markings of a flower.

**EYEBRIGHT.** *Euphrasia*.

**EYSENHARDTIA.** A genus of *Leguminosæ* nearly related to *Amorpha* and *Dalea*, but differing from the former—which has only one petal, and that the standard—in its corolla of five petals, and from the latter, in its little sabre-shaped pod being much longer than the calyx.

*E. amorphoides* is a much-branched shrub or small tree, five to twenty feet high, found in Texas and Mexico; its slender ash-coloured branches are furnished with

an abundance of pinnate leaves, and the little white pea-flowers are very numerous, and disposed in dense racemes at the ends of the twigs, succeeded by thin sabre-shaped pods. The only other species, *E. spinosa*, also a Mexican bush, has the ends of its flower spikes hardened into spiny points after the flowers have fallen. The genus bears the name of C. W. Eysenhardt, once professor in the university of Königsberg. [A. A. B.]

**FAAM, or FAHAM.** *Angræcum fragrans*.

**FABA.** The typical genus of the order *Fabaceæ* or *Leguminosæ*. It consists of annual plants rising from two to four feet high, having smooth quadrangular hollow stems; alternate pinnated leaves, formed of from two to four pairs of entire oval leaflets; and numerous large white or violet highly fragrant blossoms, marked with dark violet-coloured veins and blotches on the petals. The seeds are produced within a long green pod, or legume, and are roundish kidney-shaped, and more or less depressed or flattened.

The common Bean, *F. vulgaris*, is a hardy annual, generally believed to be a native of the shores of the Caspian Sea, as well as of Egypt and other parts of the East. It is a vegetable of very great antiquity, and is noticed in sacred history upwards of a thousand years before the Christian era (2 Samuel xvii. 28). The earlier Greeks and Athenians are stated to have cultivated beans, and offered them as a sacrifice to their gods—a practice which, according to Pliny, was in later times followed by the Romans. One of the noblest families of ancient Rome—the Fabii—derived its name from its ancestors having been celebrated for the great success which attended their culture of beans. Yet, strange to say, the most superstitious notions were entertained respecting their composition, and fitness for being used as food for man, so that some of the ancient philosophers enjoined their followers to abstain from eating them. They appear to have been known in this country from time immemorial; when, or how, they were introduced we have no information; it is, however, generally supposed to have been by the Romans.

Among the industrious classes, beans when full grown are a favourite vegetable, and considered to be very nutritious to persons with strong constitutions, but to those of a delicate habit they are not to be recommended unless in a very young state, when, if properly dressed, they form an excellent dish. There are several varieties in cultivation, which chiefly differ from one another in being tall or dwarf, early or late; or in the colour of the beans being brownish red, or green. [W. B. B.]

**FABACEÆ.** The bean or leguminous family, a natural order of calycifloral dicotyledons, better known by the name *Leguminosæ*, under which head their peculiar characteristics are described. The plants are distinguished either by their pa-

pillonaceous (pea-like) flowers, or by their fruit being a legume; in other words, a pod like that of the pea or bean. [J. H. B.]

**FABAGELLE.** (Fr.) *Zygophyllum*.

**FABIANA.** A genus of South American shrubs, belonging to the *Solanaceæ*. They have alternate scattered or overlapping leaves, and extra-axillary flower-stalks, bearing a single flower, with a tubular five-cleft calyx, and funnel-like corolla, whose tube is gradually dilated upwards, and whose limb is divided into five short lobes. The five stamens are included, and of unequal length; the anthers open by slits; the capsule is two-celled, included within the persistent calyx, and divided by two valves. *F. umbroscata* is a neat half-hardy shrub, of fastigiate habit, with white flowers, and has much of the general appearance of a leath. [M. T. M.]

**FABRICIA.** A genus of *Myrtaceæ*, consisting of New Holland shrubs, with broad oblong glaucous dotted leaves, and solitary axillary white or yellow flowers; with a bell-shaped adherent calyx-tube, and a five-cleft deciduous limb; the five petals roundish, attached to the throat of the calyx; numerous stamens, inserted with the petals, and shorter than they; and a partly-adherent many-celled ovary, each compartment containing several ovules. The fruit is a capsule opening at the top through the backs of the valves. Two or three species are in cultivation. [M. T. M.]

**FABRICOUPLIER, or FALABRIQUIER.** (Fr.) *Celtis australis*.

**FACELIS.** A little annual composite plant found in Chili, and also on the opposite side of the continent. It resembles a cudweed in appearance, and differs from its allies in having the tubular ray-florets female and in many series, and those of the disk fewer in number, more slender, and perfect. The weak stems seldom exceed eight inches high, and are furnished with numerous narrow somewhat wedge-shaped leaves; and the little narrow flower-heads, containing pink-tipped florets, are clustered at the ends of the stem. The achenes are silky, and crowned with a pappus of one series of feathery hairs. [A. A. B.]

**FACIES.** The general appearance of a plant.

**FADYENIA.** A curious West Indian aspidioid fern, remarkable for having its small sterile recumbent fronds broader than the fertile, and attenuated and proliferous at the point, the fertile being erect and blunt, almost covered by the two rows of sori. The only species is *F. prolifera*, a dwarf plant but a few inches in stature, both forms of fronds being simple. The fronds have netted veins, and are remarkable for the large size of the sori, and the very much elongated stnus of the indusium, which is reniform.

The name *Fadyenia* has also been pro-

posed by Endlicher, for the *Garrya Fadyenii* of Hooker. [T. M.]

**PAFEEER.** One of the Arabian names of *Papyrus*.

**PAGARA.** A genus of *Rutaceæ*; *Xanthoxylum*, now united with *Xanthoxylum*.

**PAGASTRUM.** This name was applied by Don to a South African shrub, which has since been referred by Professor Harvey to *Xanthoxylum*, and by Professor Oliver to *Clausena*. According to the former author, it is 'characterised by a four-parted tetrandrous flower, and a single carpel.' *P. capensis* (X. *capensis* of Harvey) is a large much-branched shrub, or small tree, the branches and twigs armed with strong horizontal prickles, usually placed under the insertion of the petiole. The fruit is called Wild Cardamom by the colonists, and is sometimes prescribed for flatulency and paralysis. [J. Br.]

**PAGE.** (Fr.) *Fagus sylvatica*.

**PAGELIA.** A genus of *Leguminosæ*, of only one species, *P. bluminostr*, a twining, strong-smelling shrub, native of S. Africa. It is more or less clothed with yellowish clammy hairs, and has ternate leaves somewhat like those of *Phaseolus multiflorus*, but smaller, with nearly triangular leaflets. The pretty yellow pea blossoms are borne on long axillary racemes. The chief distinguishing characters of the genus are, the deeply divided calyx, the obtuse keeled petal longer than the wings, and the two-seeded turgid pods, about half an inch long. [A. A. B.]

**PAGHUREH** of Avicenna. *Xanthoxylum hastile*.

**PAGOPYRUM.** The common Buckwheat and a few other species, of Asiatic origin, are included in this genus of *Polygonaceæ*. They are herbaceous plants, with erect branching stems, and heart-shaped or halbert-shaped leaves. The perianth is cut into five equal divisions, and does not increase in size along with the fruit, like that of some allied plants; and the eight stamens alternate with eight round glands. The fruit is three-sided, and not enveloped in the perianth, like that of *Polygonum*; the seed is mealy.

The common Buckwheat, or Brank as it is sometimes called, *F. esculentum*, is an annual plant with a branched stem, growing two or three feet high. It is a native of central Asia, but has been so long extensively cultivated, that it has become naturalised in various parts of Europe. In this country it is only grown to a small extent, and principally for the purpose of affording food for pheasants. On the continent, however, and also in some parts of the United States, Buckwheat is largely employed for human food; and the thin cakes made of it are said to be very delicious. As a food, its nutritious properties are greatly inferior to wheat; but it ranks much higher than rice. In France it is called Sarrasin and Blé noir. The plant is still sometimes called *Polygonum Pagopyrum*. [A. B.]

**PAGEEA.** A genus of Asiatic or Polyne-

sian *Loganiaceæ* consisting of thick-leaved trees or shrubs, sometimes found growing on loose mould that may have gathered on the stems or forks of other trees. Their chief distinguishing features consist in the border of the tubular corolla being five, rarely six to seven-lobed, the lobes twisted in the bud; and in the fruit being a two-celled berry. From most genera in the family they are readily recognised by the remarkably thick and leathery texture of their smooth and entire, usually elliptical or lance-shaped leaves. The flowers are white or cream-coloured, and often fragrant; in some very large, and thick in texture, with a trumpet-like tube, two to five inches long (in *F. auriculata*, one of the largest-flowered species, with a border six inches across); in others, where the flowers are very numerous and disposed in terminal corymbs, the corollas are much smaller. The flowers are succeeded by berries, which in the larger-flowered species are of the size of a duck's egg, and contain numerous seeds. Altogether they have much the appearance of *Gardenia*, and are chiefly distinguished by their ovaries being superior. Upwards of thirty species are known. The name *Cryptophyllum* is sometimes given to some of the smaller-flowered species. [A. A. B.]

**PAGER.** A genus of *Corylaceæ*, distinguished by having triangular nuts enclosed within a spiny capsule or husk. The most important of the few species is *F. sylvatica*, the Common Beech, a well-known European tree, and a native also of Armenia, Palestine, and Asia Minor. It forms a large and very handsome tree, especially when growing on chalky hills; and though its timber is not of the best quality, it is found extremely useful for a variety of purposes, and is also one of the best kinds of wood for fuel. The nuts or mast are, like acorns, much sought after by swine; and in some parts, where the tree abounds, the animals are driven into the beech-woods in autumn. A useful oil is also expressed from the nuts. For a full account of the uses of the Beech, the reader is referred to Loudon's *Arboretum Britannicum*.

There are some very ornamental varieties of the common Beech to be met with in cultivation; as, for example, the Purple Beech, with purple leaves; Copper Beech, with copper-coloured leaves; and Fern-leaved Beech, with the leaves variously cut into narrow segments resembling the fronds of a fern. [T. M.]

**FAIR MAID OF FRANCE.** *Ranunculus acontifolius* fl. pleno.

**FAIRY RINGS.** Green circles or parts of circles in pastures produced by various species of agarics and other *Fungi*. They appear to be generated in the following manner:—A patch of spawn, according to the fashion of many *Fungi*, spreads centrifugally in every direction, and produces a crop at its extreme edge. The soil in the inner part of the disc is exhausted, and the spawn there dies or becomes

effete. The crop of fungi meanwhile perishes and supplies a rich manure to the grass, which is in consequence of a vivid green: the parts within the ring, in consequence of former exhaustion, looking dry and parched, and those beyond less luxuriant from comparative want of manure. Thus, year after year, the ring increases in diameter till it attains dimensions of many yards across. If any accident happens to the spawn in the first instance, a part only of the circle may be developed. Rings of fungi often occur in woods, but as they grow amongst decayed leaves, the circles are seldom observed by any except professed mycologists. *Marasmius oreades*, *Agaricus gambosus*, and *A. arvensis* are amongst the most prominent inhabitants of Fairy Rings. [M. J. B.]

**FALCATE, FALCIFORM.** Pinnæ and curved in any degree, with parallel edges, like the blade of a reaper's sickle; as the pod of *Medicago falcata*.

**FALCONERIA.** The name of a few Indian trees of the spurgewort family, very nearly related to *Sapium*, and chiefly differing in having the male and female flowers on different instead of on the same tree. The species are trees of considerable dimensions, sometimes attaining a height of sixty feet, the stems abounding in a milky juice, the branches furnished with stalked smooth leaves, and the inconspicuous green flowers arranged in axillary tufted, erect or drooping spikes. The fruits are about the size of a pea. The genus bears the name of Dr. H. Falconer, an English botanist and zoologist, distinguished for his discoveries in fossil zoology. It is referred to the *Stilaginaceæ* by Lindley, but that family is now pretty generally acknowledged to be a mere group of *Euphorbiaceæ*. [A. A. B.]

**FALKIA.** A genus of *Convolvulaceæ*, containing two species, one of which is scattered pretty generally over the world, and the other confined to Mexico. They are small creeping pubescent herbs, without milky juice, and have reniform petiolate entire leaves, and cbracteate one-flowered axillary peduncles. The calyx is five-parted, and the corolla campanulate and five-cleft. [W. G.]

**FALLING STARS.** The popular name in many districts of the common *Nostoc*, which often surprises by its sudden appearance on gravel walks, after a shower, where it was unnoticed just before. Dryden alludes to this substance when singing of fairies in the following lines, more fanciful than truly poetical:—

And lest our leap from the sky prove too far,

We slide on the back of a new falling star,

And drop from above  
In a jolly of love.

[M. J. B.]

**FALL POISON.** *Amantium muscatoxicum*.

**FALSE BARK.** That layer on the outside of the stem of an Endogen, which consists of cellular tissue into which fibrous tissue passes obliquely.

**FALSE-NERVED.** When veins have no vascular tissue, but are formed of simple elongated cellular tissue; as in mosses, seaweeds, &c.

**FAN-SHAPED.** Plaited like a fan; as the leaf of *Borassus flabelliformis*.

**FAN-VEINED.** When the veins or ribs are disposed like those of a fan.

**FARIAM.** In rows: thus *bifariam*, in two rows; *trifarum*, in three rows, &c.

**FARINACEOUS.** Having the texture of flour, as the albumen of wheat.

**FARINOSE.** Covered with a white mealy substance; as the leaves of *Primula farinosa*.

**FAROUCHE.** (Fr.) *Trifolium incarnatum*.

**FARRO.** Polish wheat, *Triticum polonicum*.

**FARSETIA.** A genus of *Cruciferae*, allied to *Alyssum*, differing by the oblong pouch containing numerous seeds which have the funicle free from the body of the seed. They are natives of the Mediterranean region and temperate Asia. *Derisera* is scarcely different, the chief distinction being that the partition of the pouch is destitute of the nerve which occurs in *Farsetia*; and *Aubrieta* has a little claim to be separated on account of its seeds not being margined. Small plants, often shrubby at the base, with white, yellow, or purple flowers. [J. T. S.]

**FASCIA** (adj. **FASCIATE**). A cross band of colour.

**FASCIATED.** When a stem becomes much flattened instead of retaining its usual cylindrical figure, as in the cockscomb, &c.

**FASCIARIUS.** Narrow; very long, with the two opposite margins parallel, as the leaves of the seawrack.

**FASCICLE, FASCICLED, FASCICULATED.** When several similar things proceed from a common point, as the leaves of the larch, or the tubers of a dahlia.

**FASCICULATO-RAMOSE.** When branches or roots are drawn closely together so as to be almost parallel.

**FASTIGIATE.** Tapering to a narrow point, pyramidal; as the branches of the Lombardy poplar.

**FAT PORK.** *Clusia flava*.

**FAU.** (Fr.) *Fagus sylvatica*.

**FAUREA.** A genus of *Proteaceæ*, containing a single species, *F. saligna*, distinguished by having a club-shaped tubular silky calyx with a four-cleft limb; four stamens, with short filaments, attached to the segments of the calyx; and an ovary

covered with silky hairs, and crowned with a filiform style and oblong stigma. The fruit is a bearded nut, tipped with the permanent style. It is a small tree of South Africa, with alternate lanceolate acute subfalcate shining leaves, and bearing its flowers in solitary terminal densely crowded spikes. [R. H.]

**FAUSSE-AIRELLE.** (Fr.) *Gaylussacia*. — **CAMPANULE.** *Michauxia campanuloides*. — **GESSE.** *Vicia lathyroides*. — **IRIS.** *Morea tridivoides*. — **JOUBARBE.** *Gregoria Vitaliana*. — **LYCHNIDE.** *Nycterina Lychnidea*. — **PÂQUERETTE.** *Bellium bellidoides*. — **RENOCULE.** *Anemone ranunculoides*. — **VIPELINE.** *Onoma echinoides*.

**FAUX.** The orifice of a calyx or corolla.

**FAUX-ACACIA.** (Fr.) *Robinia*. — **ARMERIA.** *Armeria Pseudo-Armeria*. — **BAGUENAUDIER.** *Coronilla Emerus*. — **COTONNIER.** *Gomphocarpus fruticosus*. — **DRAGONNIER.** *Yucca Dracoms*. — **EBENIER.** *Cytisus Laburnum*. — **FRAISIER.** *Potentilla Fragariastrum*. — **HILLOTROPE.** *Tournefortia*. — **INDIGO.** *Amorpha fruticosa*. — **JALAP.** *Mirabilis Jalapa*. — **LISERON.** *Polygonum Convolvulus*. — **MUSCARI.** *Muscari monstrosum*. — **NARCISSE.** *Narcissus Pseudo-Narcissus*. — **NEFLIER.** *Pyrus Chanemecypilus*. — **NERPRUN.** *Hippophae rhamnoides*. — **PARTHÉNŪM.** *Anthemis parthenioides*. — **PERSIL.** *Ethusa Cynapium*. — **PIMENT.** *Solanum Pseudo-capsicum*. — **PISTACHIER.** *Staphylea pinnata*. — **PLATANÉ.** *Acer Pseudo-Platanus*. — **SAFRAN.** *Carthamus tinctorius*. — **SAPIN.** *Abies excelsa*. — **SÈNÉ.** *Colutea arborescens*. — **TEUCRIUM.** *Verbena teucrioides*. — **THUJA.** *Cupressus thuyoides*. — **TREMBLE.** *Populus tremuloides*. — **TURBITH.** *Thapsia villosa*.

**FAVA DE S. IGNACIO.** *Antispermia Passiflora*.

**FAVELLÉE.** A term applied by algologists to those capsules in *Algae* in which the nucleus, consisting of many spores, is formed within a single mother-cell, as in *Ceramium*. When several contiguous cells are fertile, the group is called a *favellidium*. Sometimes a coecidium, when enclosing a multitude of nuclei, or favellus, is called a *favellidium*. [M. J. B.]

**FAVEOLATE.** Honeycombed. The same as *Favose*.

**FAVIOLLE À BOUQUETS.** (Fr.) *Phaeotus multiflorus*.

**FAVOSE.** Excavated in the manner of a section of honeycomb, as the receptacle of many composites.

**FAVOSO-AREOLATE.** Divided into spaces resembling the cavities of honeycomb.

**FAVOSO-DEHISCENT.** Appearing honeycombed after dehiscence, as the anther of *Viscum*.

**FAYARD.** (Fr.) *Fagus sylvatica*.

**FAY-BERRY.** *Ribes Grossularia*. The same as *Fea-berry*.

**FEA-BERRY.** *Ribes Grossularia*.

**FEATHER-FEW** or **FEATHER-FULLY.** *Pyrethrum Parthenium*.

**FEATHERFOIL.** *Hottonia*.

**FEATHER-VEINED.** Having veins which proceed from a midrib at an acute angle.

**FEATHERY.** Consisting of long hairs which are themselves hairy, as the puppus of *Leontodon Taraxacum*.

**FEDIA.** A synonym of *VALERIANELLA*: which see.

**FÉE.** A small genus of hymenophylloid ferns, separated from *Trichomanes* by their dimorphous fronds, and from *Hymenostachys*, which has dimorphous fronds, by their free veins. They are dwarf tropical subpellucid plants, with the sterile fronds pinnatifid or pinnate, and the fertile ones reduced to a mere spike with marginal cysts containing the spore cases. [T. M.]

**FEELE-WORT.** *Catasetum*.

**FELIOA.** A Brazilian genus of *Myrtaceæ*, having the habit of *Peidium*, from which it is easily distinguished by its stamens. There is but one species. It is remarkable in the order for its albuminous seeds. [J. Br.]

**FELICIA.** A genus of *Compositæ*, separated from *Aster* chiefly by its short universal withering pappus, the hairs of which are filiform, flexuose, and serrulate. They are herbs or suffrutescent plants of the Cape of Good Hope, with branching stems, narrow alternate leaves, and flower-heads with usually white or blue rays. One of the species, *F. tenella*, is sometimes cultivated among annuals under the name of *Aster tenellus*. [T. M.]

**FELLEUS.** Bitter as gall.

**FELONWORT**, or **FELON-WOOD.** *Solanum Dulcamara*, from its former use in curing whitlows or felons.

**FELWORT.** *Scutella*; also an old name for *Gentiana lutea*.

**FELOUGNE.** (Fr.) *Chelidonium majus*.

**FEN-BERRY.** *Oxyococcus palustris*.

**FENDLERA.** The shrub so named in honour of a well-known botanical collector, belongs to the order *Philadelphaceæ*. The tube of the calyx is marked with eight ridges, the limb four-parted; petals four, deltoid, stalked, irregularly notched; stamens eight, the filament prolonged beyond each side of the anther, into a linear lobe, and the anthers provided with a

small apiny point; styles more or less consolidated, permanent on the four-celled capsular fruit. [M. T. M.]

**FENESTRA** (adj. **FENESTRATE**). An opening through a membrane, like a window in a wall.

**FENNEL**. *Faniculum vulgare*. —, **AZOREAN**. *Faniculum dulce*. —, **GIANT**. *Ferula*. —, **HOG'S**, or **ROW**. *Peucedanum officinale*. —, **SWEET**. The *Fiuocchio*, *Faniculum dulce*.

**FENNEL-FLOWER**. *Nigella*.

**FENOUIL**. (Fr.) *Faniculum*. — **BÂTAID**. *Anethum graveolens*. — **DE MER**. *Orithium maritimum*. — **DE PORC**. *Peucedanum officinale*.

**FENUGREEK**. *Trigonella Fœnum græcum*.

**FENU-GREC**. (Fr.) *Trigonella Fœnum græcum*.

**FENZLIA**. A genus of tropical New Holland shrubs, belonging to the *Myrtaceæ*. They are covered by bran-like scales, and have thick entire leaves, and rose-coloured flowers on short axillary stalks. The calyx has two bracts at the base, a globose tube, and a limb of five acute, spreading segments; petals five; stamens numerous, shorter than the petals, with globular anthers, whose two cells are separated by a thickened connective, and which open by long clefts. The fruit is a berry, crowned by the calyx-limb, one-celled, one-seeded by abortion. [M. T. M.]

The name *Fenzlia dianthiflora* is applied in gardens to a beautiful dwarf Californian annual belonging to the *Polemoniaceæ*, which in cultivation forms a closely ramified spreading tuft, bearing a profusion of its delicate rosy-tinted flowers with a yellow throat, surrounded by five dark-coloured dots. These flowers have a tubulose-campanulate deeply five-cleft calyx, and a funnel-shaped corolla, with broad spreading obovate dentate limb segments. This plant is more correctly called *Gilia dianthoides*. [T. M.]

**FER**, **FERUS**. A Latin termination signifying the carrying of something, as *florifer*, the carrier of flowers.

**FERRUGINOUS**. Light brown, with a little mixture of red.

**FERDINANDA**. A genus of yellow-flowered Mexican bushes of the Composite family, nearly allied to *Helopsis*, from which they are easily recognised by having numerous small flower-heads arranged in corymbs at the ends of the branches, instead of single and large flower-heads. The alternate or opposite leaves are rough; and the flower-heads have an involucre of one to three series of narrow scales, the outer row of florets being strap-shaped and female, the inner tubular and perfect. The achenes are four-sided, each embraced by a chaffy scale, and seated on a conical receptacle; the pappus is entirely absent,

or present in the outer florets in the form of two to five scales. [A. A. B.]

**FERDINANDEZIA**. A genus comprising ten species of epiphytal orchids from tropical America. They differ more in habit than character from *Oncidium*; and have slender stems thickly covered with overlapping triangular leaves, the edges, instead of the flattened portion, pointing upwards; the flowers are small, yellow, and disposed in axillary racemes or panicles from the axils of the upper leaves; the two pollen-masses are pear-shaped, without a caudicle, and attached to a small ovate gland. The species have much in common. *Lochneria* is another name for the genus. [A. A. B.]

**FERDINANDUSA**, or **FERDINANDIA**. These names both refer to the same genus of *Cinchonaceæ*, which consists of Brazilian trees, with leathery leaves; and the flowers in panicles, with a funnel-shaped corolla, whose limb is divided into four ovate notched revolute segments, and four stamens slightly protruding from the corolla. The fruit is a two-celled capsule bursting by two valves, which separate also from the calyx, which is cleft lengthwise; the seeds are winged. [M. T. M.]

**FER-Â-CHEVAL**. (Fr.) *Hippocrepis unisiliquosa*.

**FERN**, **REECH**. *Polypodium Phegopteris*. —, **BLADDER**. *Cystopteris*. —, **BRISTLE**. *Trichomanes*. —, **BUCKLER**. *Lastrea*. —, **CINNAMON**. *Osmunda cinnamomea*. —, **CLIMBING**. *Lygodium*. —, **FEMALE**. *Athyrium Filix-femina*; also *Lastrea Thelypteris*, and *Pteris aquilina*. —, **FILM**. *Hymenophyllum*. —, **FLOWERING**. *Osmunda*, and also *Anemia*. —, **HARD**. *Blechnum Spicant*. —, **HARE'S-FOOT**. *Davallia canariensis*. —, **HOLLY**. *Polystichum Lonchitis*. —, **LADY**. *Athyrium Filix-femina*. —, **LIP**. *Chellanthus*. —, **MAIDEN-HAIR**. *Adiantum Capillus Veneris*. —, **MALE**. *Lastrea Filix-mas*. —, **MARSH**. *Lastrea Thelypteris*. —, **MOUNTAIN**. *Lastrea montana*. —, **OAK**. *Polypodium Dryopteris*. —, **OSTRICH**. *Struthiopteris*. —, **PARSLEY**. *Allosorus crispus*; also sometimes applied to *Athyrium Filix-femina crispum*. —, **POD**. *Ceratopteris thalictroides*. —, **RATTLESNAKE**. *Botrychium virginicum*. —, **ROYAL**. *Osmunda regalis*. —, **ROYAL OF CALABR**. *Lübrochia Orreri*. —, **SCALE**. *Ceterach*. —, **SENSI-TIVE**. *Oncoclea sensibilis*. —, **SHIELD**. *Aspidium*. —, **STONE**. *Allosorus crispus*. —, **SUN**. *Polypodium Phegopteris*. —, **SWEET**. *Lastrea fragrans* and *montana*. —, **SWORD**. *Xiphopteris*. —, **TARA**. *Pteris esculenta*. —, **WALKING**. *Camptosorus rhiphyllus*. —, **WALL**. *Polypodium vulgare*. —, **WATER**. *Osmunda*. —, **WOOD**. A name applied to the American *Lastreas*.

**FERN-BUSH**, **SWEET**. An American name for *Comptonia asplenifolia*.

**FERN-ROOT**, **TASMANIAN**. The caudex of *Pteris esculenta*.

**FERNS.** The highest of the sub-groups of Acrogens, technically called **FILICES**: which see.

**FERONIA.** The Wood-apple or Elephant-apple tree of India, *F. elephantum*, is the only species of this genus of *Murantiaceæ*. It is common throughout India, Burmah, Ceylon, and Java, and forms a large tree, yielding a hard, heavy wood, of great strength but not durable. When wounded, there flows from it a transparent gum, which is mixed with other gums and sent to this country under the name of East Indian Gum Arabic. The tree has pinnate leaves composed of shining stalkless leaflets, and the flowers are arranged in racemes, containing a mixture of male, female, and perfect blossoms; these have a flat five-toothed calyx, five (occasionally four or six) white spreading petals, ten stamens, and a five-celled ovary. The fruit, which is about the size of an apple, has a very hard, rough, woody rind, and contains a pulpy flesh with numerous seeds imbedded in it. This pulp is eatable, and, like that of the Bengal quince, which is the fruit of a closely allied tree, it exerts a beneficial action in cases of dysentery and diarrhoea; a jelly resembling black currant jelly is also prepared from it. The leaves have an odour like that of anise, and the native Indian doctors employ them as a stomachic and carminative. [A. S.]

**FERRARIA.** A genus of Cape *Iridaceæ*, with tuberous rhizomes, simple or paniculately branched stems, two-ranked ensiform thick nervose glaucous leaves, and very fleeting flowers, which consist of a six-parted perianth, with oblong undulated spreading or reflexed segments, the exterior ones being broader than the others; three stamens, with the filaments connate into a tube; and a three-celled many-seeded ovary, surmounted by a filiform style, and three dilated petaloid multilobed stigmas. The flowers are highly curious, but dingy, and very fugacious. [T. M.]

**FERTILE.** Having the power of producing perfect seeds; or fertilised; or producing a large quantity of seeds.

**FERULA.** A genus of *Umbellifera* characterised by the presence of compound umbels, variable involucrea, a five-toothed calyx, ovate pointed petals, and compressed fruits: each half of which is surrounded by a membranous border, and has three thread-like ridges, the two lateral ones losing themselves in the wing-like margin. There are three or more channels for oil in the furrows between the ridges, and four on the surface that touches the other half of the fruit.

The species are natives of the Mediterranean and Persian regions, with tall-growing pithy stems and deeply-divided leaves, the segments of which are frequently linear. *F. communis* attains sometimes in English gardens a height of fifteen feet, and is known under the name of Giant Fennel. It is a common plant in

Sicily, where the pith in the interior of the stem is used for tinder. *F. persica*, a dwarf species, was formerly supposed to be the source of asafoetida, but the greater portion of this drug is the produce of *Narthex Asafoetida*. *F. orientalis* and *F. tingitana* are said to yield African Ammoniacum, a gum-resin like asafoetida, but less powerful. Sagapenum, a similar drug, is supposed likewise to be the produce of some species of this genus, but great uncertainty prevails on the subject. [M. T. M.]

**FESTUCA.** A very extensive genus of grasses, typical of the tribe *Festuceæ*. The species have either a panicle or racemed inflorescence, with flattened spikelets, which are two to many-flowered; glumes two, unequal, thinner than the pales, which latter are ribbed, rounded on the back, acute, with the seta terminal or nearly so; stamens three, rarely one to two; styles two, short; stigmas feathery. The genus embraces about 200 species, which have a wide geographical range over nearly the whole surface of the globe, and are divided into four sections, namely, *Nardurus*, *Sclerocloa*, *Vulpia*, and true *Festuceæ*. There are nine of the species natives of Britain, and among them some of our most valuable meadow and pasture grasses. *F. pratensis*, the Meadow Fescue, and *F. durtuscula*, the Hard Fescue, are both excellent kinds, and highly prized for agricultural purposes. *F. ovina*, the Sheep's Fescue, is important for subalpine pastures, where it grows freely, and is much relished by sheep. It is also useful for forming lawns, where the grass is required to be kept short and neatly dressed. Many of the foreign species are also useful for the same purposes, especially *F. heterophylla*, *Halleri*, and *rupestris*. Although the Fescue grasses are rather remarkable among the family, for the large quantity of saccharine matter in their composition, one species, *F. quadridentata*, is said to be poisonous in Quito, where it is called *Pigoni*. See *Lindley's Vegetable Kingdom*, p. 112. [D. M.]

**FETID.** Having a disagreeable smell of any kind.

**FÉTUQUE.** (Fr.) *Festuca*. — **DES BREBIS.** *Festuca ovina*. — **TRAÇANTE.** *Festuca rubra*.

**FEVILLÆA.** A genus of tropical American *Cucurbitaceæ*, belonging to the small section of that order which is distinguished by the anthers not being sinuous. The species are perennial herbaceous plants, with rather woody stems, climbing up trees to a great height and supporting themselves by means of tendrils, which are said to proceed from the axils of the leaves, instead of from the sides as in the common gourd. They have large, roundish, smooth leaves, frequently lobed, and the male and female flowers are borne on distinct plants, both having a five-lobed calyx, and a wheel-shaped corolla with five divisions. The fruit is globular and has a woody shell, marked with a scar which forms a zone round it, and shows the division between

the enlarged calyx and the shell of the fruit; it contains a number of large flat seeds embedded in solid flesh, and does not split open when ripe.

*F. cordifolia* is the Séqua or Cacaoon Antidote of Jamaica, where it is a common plant in shady woods, climbing to a great height up the trunks of trees. The fruits are four or five inches in diameter, and contain from twelve to fifteen large flat seeds, which possess purgative and emetic properties and have an intensely bitter taste. In Jamaica the negroes employ them as a remedy in a variety of diseases, and consider them to be an antidote against the effects of poison; they also obtain a large quantity of semi-solid fatty oil, which is liberated by pressing and boiling them in water.

The seeds of an allied species called *Abilla* in Peru, contain so much oil that the Peruvians use them for making candles. These are made by cutting cubical pieces of the seed and stringing them upon a thin piece of stick, the point of which is lighted. The candles thus rudely constructed, burn well, with a tolerably clear light, and, not being readily extinguished by wind, are commonly used in the open-air processions of the Roman Catholic Church. Another curious use is made of these *Abilla* seeds: the shell is lined with a soft felt-like substance, which when dry forms an excellent tinder, and the Indian, by rapidly twirling a pointed stick upon it, soon obtains a light; thus the same seed furnishes him with his candle, and with tinder for lighting it. [A. S.]

FEVE, or F. DE MARAIS. (Fr.) *Faba vulgaris*.

FEVER-BUSH. An American name for *Benzoin*.

FEVERFEW. *Pyrethrum Parthenium*. —, BASTARD. *Parthenium Hysterophorus*.

FÉVEROLLE. (Fr.) *Faba vulgaris*.

FEVERWORT. *Triosteum*.

FÉVIER. (Fr.) *Gleditsia*. — D'AMÉRIQUE. *Gleditsia triacanthos*.

FIBRE, ELEMENTARY. That thread which is turned round the interior of the tubes that are called spiral vessels, or of any similar kind of tissue.

FIBRILLÆ (adj. FIBRILLOSE). The roots of lichens; any kind of small thread-shaped root; also applied occasionally among fungals to the stipe.

FIBROUS. Containing a great proportion of woody fibre; as the rind of a cocoa-nut.

FIBRO-VASCULAR. Consisting of woody tissue and spiral or other vessels.

FICAIRE. (Fr.) *Ficaria ranunculoides*.

FICARIA. This genus is distinguished from *Ranunculus* by its having three deciduous instead of five persistent sepals,

and nine petals instead of five; in all other respects it is a true crowfoot; indeed, our native species, *F. ranunculoides*, is not unfrequently described under the name of *Ranunculus Ficaria*. Though called Small Celandine and Lesser Celandine, it is totally distinct from the true celandine (*Chelidonium*). Being one of the earliest of British flowering plants, and its petals being of a beautiful golden-yellow, and its leaves a glossy green, it is a general favourite. Its roots consist of a number of small fleshy tubers, which store up nourishment like bulbs during the whole of the summer and autumn. Gerard's description of its duration is worth quoting for its accuracy and quaintness: 'It cometh forth about the calends of March, and flourisheth a little after; it beginneth to fade away in April, it is quite gone in May, afterwards it is hard to be found, yea, scarcely the root.' This might be taken for an allegorical epitome of the life of man. The young leaves of *Ficaria*, according to Linnæus, are sometimes used as greens in Sweden. A variety with double flowers is occasionally cultivated. French, *Petite Chelidone*; German, *Feigmarunkel*. [C. A. J.]

The trivial name of Pilewort has been bestowed upon this plant from the structure of its tubercles, which grow in bundles of small tubers, so like the shape of those excrescences which occur in the more distressing cases of piles (hemorrhoids), that our forefathers, who chose their medicines, not from a knowledge of the properties and qualities of the plants, but from a kind of fancy as to Nature's external impress indicating innate virtues, adopted it as a remedy for this malady. Culpepper is most enthusiastic in describing its virtues: 'Here is another secret for my countrymen and women—a couple of them together. Pilewort made into an oil, ointment, or plaster, readily cures both the piles, or hemorrhoids, and the king's-evil. The very herb borne about one's body next the skin helps in such diseases, though it never touched the place grieved. Let poor people make much for their uses. With this I cured my own daughter of the king's-evil.' Confident as are these assertions, yet the use of the plant is all but discontinued in the present day, medical practitioners very properly looking for sounder principles than those derived from the doctrine of similitudes.

In *Green's Universal Herbal* we find the following observations:—'The particular form of the roots probably recommended this plant as a cure for the piles; and this fancied quality was the origin of the English name. The roots are sometimes washed bare by the rains; and this induced the ignorant and superstitious to imagine that it rained wheat, to which the uncovered tubercles bear a little resemblance.' That this plant, from these and other reasons, was long considered as a 'herb of grace,' there can be no doubt; however, it is at present looked upon principally as a weed which can best be got rid of, when trouble-

some, by opening drains and thinning out trees or thickets. [J. B.]

**FIGINIA.** A genus of cyperaceous plants belonging to the tribe *Scirpeæ*. The inflorescence is either in solitary spikes or in conglomerated heads of spikes. Scales imbricated, some of the lower empty; styles three-cleft, rarely two-cleft; ovary with a fleshy disc; achenes sharply pointed or muticous. There are upwards of forty species, nearly all of which are natives of South Africa. [D. M.]

**FICOIDALES.** One of Lindley's alliances of perigynal Exogens, represented by *Mesembryanthemum*.

**FICOIDE.** (Fr.) *Mesembryanthemum*.

**FICOIDEÆ,** or Fig-Marigold family. A natural order of calycifloral dicotyledons, the type of Lindley's ficoid alliance. The order is better known as *Mesembryaceæ* or *Mesembryanthemaceæ*. [J. H. B.]

**FIGUS.** A genus of *Moraceæ*, including the cultivated Fig. The flowers are usually incomplete, collected on axillary receptacles, which are either stalked or sessile, pear-shaped or globular, with three bracts at the base. There is a four to six-leaved perigone; in the staminate flowers one to six stamens; and in the pistillate a one-celled ovary. The fruit consists of globose or angular achenes, with a dry thin rarely pulpy pericarp. They are erect or creeping trees or shrubs, found in Southern Europe and Africa, and in large numbers in the warm parts of India, and in the islands of the Indian Sea and of the Southern Ocean. They have alternate rarely opposite entire or lobed leaves. There are nearly 160 known species. Of the cultivated Fig there are a vast number of varieties. The part eaten is the hollow receptacle which contains the flowers. The achenes, or, as they are commonly called, seeds, are ultimately immersed in the pulpy mass of the receptacle. Turkey figs are imported from Smyrna in small boxes called drums. From the old genus *Ficus*, Miquel has separated the genus *Urostigma*, *Pharmacosycea*, *Pogonotrophe*, *Sycomorus*, *Covilla*, and *Synocia*. See Plate 6, figs. a, f; and Plate 10, fig. b. [J. H. B.]

The Fig of our gardens is the *F. Carica* of botanists. The name *Ficus* applied to this very anciently known fruit, is most probably derived from *Feg*, its Hebrew name; that of *Carica* is from *Caria* in Asia Minor, where fine varieties of it have long existed. According to various authors, it is a native of Western Asia, Northern Africa, and the south of Europe, including Greece and Italy. It is certainly indigenous to Asia Minor; but it may have been thence introduced and naturalised in the islands of the Mediterranean, and the countries near its shores, both in Europe and Africa.

The Fig is a deciduous tree, fifteen to twenty or even thirty feet high in favourable climates. The alternate leaves are cordate, more or less deeply three to five-

lobed, and rough. The fruit is generally shortly turbinate, but some varieties are of an elongated pyriform shape; the skin soft, with shallow longitudinal furrows; the colour yellowish-white, greenish-brown, purplish-brown, violet, or dark purple. It consists of a hollow fleshy receptacle with an orifice in the top, which is surrounded and nearly closed by a number of imbricated scales—as many as 200, according to Duhamel. The flowers, unlike those of most fruit-trees, make no outward appearance, but are concealed within the fig on its internal surface; they are male and female, the former situated near the orifice, the latter in that part of the concavity next the stalk. On cutting open a fig, when it has attained little more than one-third its size, the flowers will be seen in full development, and, provided the stamens are perfect, fertilisation takes place at that stage of growth. But it often happens that the stamens are imperfect, and no seeds are formed; nevertheless the fruit swells and ripens.

Under favourable circumstances, a fruit or two is formed along the shoots at the base of almost every leaf. Of these the quantity that sometimes attains maturity is enormous; but frequently, from vicissitudes of cold in some climates and heat in others, much of the fruit drops prematurely. It may not do so at the time when dryness prevails, but at some future period when moisture is sufficiently abundant; in fact, the injury caused by drought to this fruit becomes most apparent after moisture has started the tree into vigorous growth, and hence the true but remote cause of failure in the crop is apt to be overlooked. And if this be sometimes the case now, it was much more likely to be generally so in former times, when there was among cultivators but little intelligence as regards tracing effects to their causes. Accordingly, to prevent the fruit of the Fig tree from dropping prematurely, and to hasten its ripening, the process of *capriciation* was resorted to. This consisted in placing the fruit of a wild sort, called the *Caprifig*, amongst the cultivated ones. An insect of the gnat family infests the former, which it leaves to attack the latter, entering to the interior of the fruit by the orifice. It is a very ancient practice, for it is mentioned by the earliest Greek writers on natural history, and is even minutely described by Theophrastus. It appears to have originated in Greece. Pliny remarks that it was only used in the islands of the Archipelago; that, in his time, it was entirely unknown to the Italians; and that there was no tradition of its ever having been introduced to Syria or Palestine. Its utility was doubted by some authors, and among others by the celebrated Duhamel. He thought it questionable whether by capriciation the maturity of the fruit was hastened, except in the same way as apples and pears are when attacked by the grub. Professor Gasparriani, in an essay written for the Royal Academy of Sciences of Naples, details a number of

experiments which he had made, and repeated in different years. Their results led to the conclusion that caprification is useless for the setting and ripening of the fruit, and instead of making the figs remain on the tree, it either causes or facilitates their fall, especially when the insect has penetrated into the inside, and produced decay by its own death. According to Gasparini, the practice of caprification ought to be abolished, as it entails expense, and deteriorates the flavour of the figs. The French naturalist, Oliver, says it is being abandoned in some islands of the Archipelago where it was formerly practised, but in which excellent figs are still produced. We have thought it necessary to briefly notice the operation, as so much has been written with regard to its presumed advantageous effects; but from what has been stated, it will be seen that, according to the investigations of modern science, it is proved to be not only unnecessary, but positively injurious.

Figs have been used in the east as an article of food from time immemorial. They were amongst the fruits brought back from Canaan by the Israelites sent by Moses to report on the productions of that land. We read of a present having been made to David of 200 cakes of figs. They were probably used chiefly in the dried state. The drying is easily effected in a warm climate by exposure to the sun's rays, in the same way as those grapes are dried, which are culled from that circumstance raisins of the sun. Like the grape, the substance of the fig abounds in what is termed grape sugar. In drying, some of this exudes and forms that soft white powder which we see on the imported dried figs. They are thus preserved in their own sugar, and rendered fit for storing up as an article of food.

Figs were considered of such necessity by the Athenians that their exportation from Attica was prohibited. Those who informed against persons violating this law were called 'Sycophantæ,' from two Greek words signifying the discoverers of figs. These informers appear to have been especially disliked, for their name gave rise to the term sycophant, used for designing liars and impostors generally, as well as flatterers.

The Figs of Athens were celebrated for their exquisite flavour; and Xerxes was induced by them to undertake the conquest of Attica. The African figs were also much admired at Rome, although Pliny says, 'It is not long since they began to grow figs in Africa.' Cato, in order to stimulate the Roman senators to declare war against Carthage, showed them a fig brought from thence. It was fresh and in good condition, and all agreed that it must have been quite recently pulled from the tree. 'Yes,' said Cato, 'It is not yet three days since this fig was gathered at Carthage; so by it how near to the walls of the city we have a mortal enemy.' This argument determined the senate to commence the third Punic war, the result of

which was that Carthage, the rival of Rome, was utterly destroyed.

Only six varieties of Figs were known in Italy in the time of Cato. Others were introduced from Negropont and Scio, according to Pliny, who gives a catalogue of thirty sorts. The fig may have been introduced into Britain, along with the vine, by the Romans, or subsequently by the monks. But if it had, it seems to have disappeared till brought from Italy by Cardinal Pole, either when he returned from that country in 1525, or after his second residence abroad in 1548. In either case the identical trees which he brought, and which were planted in the garden of the Archiepiscopal Palace at Lambeth, have certainly existed for more than 300 years. This proves that the fig lives to a great age, even under less favourable circumstances than it enjoys in its native country. Another tree, brought from Aleppo by Dr. Pocock, was planted in the garden of one of the colleges at Oxford in 1648. Having been injured by fire in 1806, the old trunk decayed and was removed, but fresh shoots sprang up, some of which in 1819 were twenty-one feet high. In this country a chalk subsoil, and a climate like that near the south coast, appear to suit the fig best. There the trees grow and bear as standards. They are liable, however, to be killed to the ground in winters of excessive severity; but they spring up afresh from the roots. There was an orchard, not exceeding three-quarters of an acre, at Tarring, near Worthing, in Sussex, containing 100 standard fig-trees. About 100 dozen of ripe figs were usually gathered daily from these trees during August, September, and October. By selecting similarly favourable spots, it may be fairly concluded that this country could supply itself with abundance of fresh figs. As for dry ones, they are obtained in large quantities from Turkey, the Mediterranean, and other countries; but the supply for centuries back has chiefly been from Turkey. The import has been as much as 1,000 tons a year; and now that the duty is taken off, the quantity imported will doubtless be much greater. The wood of the Fig is soft and spongy; and as it ran in consequence be easily charged with oil and emery, it is used in some countries by locksmiths and armourers for polishing.

[R. T.]

**FIDDLE-SHAPED.** Obovate, with one or two deep recesses or indentations on each side, as the leaves of the fiddle-dock, *Rumex pulcher*.

**FIDDLEWOOD.** *Citharexylon*.

**FIDUS, FISSUS.** Divided half-way into two or more parts.

**FIELDIA.** A genus of Australian *Geraneaceæ*, having only a single species, *F. australis*. It has a five-parted calyx with blind apathaceous bracts; a tubular swollen corolla, with a five-parted slightly two-tipped limb; five stamens, four of which are fertile; and a style scarcely as long as

the stamens, terminating in a bilamellar stigma. The fruit is an ovate many-seeded berry. The plant has opposite, remote, shortly-stalked broadly lanceolate leaves, and axillary, solitary pendulous flowers of a pale green colour. It is a climber, with a rooting stem, attaching itself to the trunk of tree ferns, &c. The name is sometimes applied to certain *Vandus*. [R. H.]

FIG. *Ficus*. — ADAM'S. *Musa paradisiaca*. — BARBARY. *Opuntia vulgaris*. — COMMON. *Ficus Carica*. — DEVIL'S or INFERNAL. *Argemone mexicana*. —, HOTTENTOTS. *Mesembryanthemum edule*. —, INDIAN. *Opuntia*, especially *O. vulgaris*; also a general name for the *Cortaceæ*. — KEG, of Japan. *Diospyros Kaki*. — PHARAOH'S. *Sycomoros antiquorum*. —, SACRED. *Ficus religiosa*.

FIG-MARIGOLD. *Mesembryanthemum*.

FIGUE BANANE. (Fr.) *Musa sapientum*. — CAQUE. *Diospyros Kaki*. — MODIQUE. *Cusia flava*.

FIGUIER. *Ficus*. — COMMUN. *Ficus Carica*. — D'ADAM. *Musa paradisiaca*. — D'INDE. *Opuntia vulgaris*.

FIG-WORT. *Scrophularia*. The term Figwort has also been applied to the scrophulariaceous order.

FILAMENT. The stalk of the anther. Any kind of thread-shaped body.

FILAGO. A genus of small herbaceous *Compositæ*, distinguished by their chaffy receptacle, the absence of a pappus, and by the female florets being mixed among the scales of the imbricated involucre. They are mostly annuals of low stature, having the stems and leaves hoary with cottony down, and inconspicuous flowers of the texture popularly known as everlasting. The commonest British species are *F. minima*, a hoary little plant three to four inches high, with erect stems, very narrow leaves, and brownish-yellow flowers; and *F. germanica*, a plant of similar habit, six to eight inches high, with an erect stem terminating in a globular head of small conical flowers, from the base of which usually spring two or three horizontal branches terminating in like manner. This curious mode of growth occasioned the term *Herba impta* to be applied by the old botanists to this plant, as if the offspring were unduly elevating themselves above the parent. None of the foreign species are worthy of especial notice. French, *Colonnière*; German, *Filstraut*. [G. A. J.]

FILBERT. *Corylus Avellana*. —, WEST INDIAN. *Entada scandens*.

FILFIL BURREE. An Indian name for the fruits of *Vilox trifolia*.

FILIOES. One of the principal groups of cryptogams, some of the leading peculiarities of which will be found explained in the article ACROGENS. They are commonly called Ferns, and consist of arborescent or herbaceous perennial, very rarely annual plants; those of arborescent

habit having a trunk varying from two or three to sixty or eighty feet in height, and formed of the consolidated bases of the fronds, surrounding a soft central mass of tissue; those of herbaceous habit either having a caudex formed on a plan similar to the arborescent kinds, but on a smaller scale, the young fronds forming the growing point, or having a more or less fleshy rhizome whose growing point is in advance of the development of the fronds, which are produced from its sides instead of its apex. Arborescent Ferns are represented in Plates 2, fig. 4, 9, and 12; and a simple-fronded Fern in Plate 12.

All true Ferns, under which name are included nearly all the ferns that are known, may be recognised by the circinate growth of their young leaves, and by their hypophyllous fructification. The fronds are very various in regard to size and form, some being simple, others many times cut or divided; while some measure but an inch, and others many feet, in length. In the majority of instances there is no material difference of aspect between those fronds which are fertile and those which are sterile; but in others, including whole groups, the *acrosticheæ* for example, there is a manifest contraction of the fertile fronds, which are sometimes reduced to mere ribs and spikes clustering with masses of the spore-cases.

The spore-cases, which are collected into heaps called sori, consist of little one-celled vesicles, girt either longitudinally, vertically, or obliquely by a jointed ring, which nearly, or in some cases completely, surrounds them. This ring is elastic, and by its contraction disrupts the spore-case and scatters the contained spores—mere dust-like atoms, invisible except in a mass to the naked eye. The sorus, or heap of spore-cases, is in some groups naked, but in others covered while young by a membrane called the indusium.

The spores of Ferns are produced by cell-division within the spore-cases, and are consequently unattached, and variously shaped and sculptured. They consist of two coats containing a grumous mass. On germination the outer coat bursts, and the inner is elongated and protruded, and by cell-division becomes converted into a thin marchantiform frond or prothallus. On the under-surface of the prothallus, two kinds of bodies are borne, one of which, the antherid, produces spiral ciliated spermatozooids, while the other, which forms the archegone or female cell, is sunk in the tissue. The cell at the base of the archegones, after impregnation, gives rise to a new plant, which is gradually developed, and is of different duration in different species, producing successive crops of fronds and spore-cases.

Many schemes have been proposed for the classification of Ferns, but that seems to be preferable, which is based on the modifications of the vascular system taken in conjunction with the fructification. All Ferns are referrible to one of the groups *Ophioglossaceæ*, *Marattiaceæ*, or *Polypodi-*

VEGETATION OF JAVA TREE FERNS IN THE FOREGROUND A FOREST OF  
AMENTACEAE IN THE DISTANCE  
(After Blume)

case, of which the two first, sometimes called pseudo-Ferns, are very limited, while the latter, containing the true Ferns, includes the greater portion of all the known species.

The three groups just named are distinguished from each other by the nature and structure of their spore-cases. The presence of the annulus or ring around the spore-case, in some form, either completely surrounding it, or in a more or less rudimentary condition, is the distinctive peculiarity of the *Polypodiaceæ*; while the *Marattiaceæ* and the *Ophioglossaceæ* are separated from it by the absence of any such ring, rudimentary or otherwise, and are distinguished from each other by the obvious characters that the *Marattiaceæ* have their sori dorsiferous, that is, on the back or under surface of their fronds, as is commonly the case among true Ferns, while the *Ophioglossaceæ* have their sori marginal, the spore-bearing or fertile fronds being contracted. The *Ophioglossaceæ* are few in number, and present little difference of structure; the *Marattiaceæ*, however, form three small tribes, of which the *Marattineæ* have their sori ranged in two lines facing each other, forming distinct oblong masses; the *Kaulfussineæ* have distinct circular sori, the spore-cases of each sorus being concrete into a single annular series, and furnished with openings towards the centre; and the *Danettineæ* have their sori connate over the whole under surface, which then shows long parallel lines of small round cavities.

The *Polypodiaceæ* offer so much variety of structure that it becomes necessary to subdivide them, and for this purpose the peculiarities in the form of the spore-cases, or in their number and position, or in the structure and development of the annulus or ring, are most relied on. This gives the following groups:—*Polypodiaceæ*, the most extensive of all, with spore-cases almost equally convex, having a vertical and nearly complete ring, and bursting transversely at a part on the anterior side, called the stoma, where the strise of the ring become dilated into elongate parallel cells. *Cyatheaceæ*, with spore-cases sessile or nearly so, seated on an elevated receptacle, oblique-laterally compressed, the nearly complete ring being, in consequence, more or less obliquely vertical, that is, vertical below, curving laterally towards the top, bursting transversely; they approach very near the *Polypodiaceæ*, through some species of *Aisophila*, in which the characteristic obliquity of the ring is little apparent. *Matoniaceæ*, a single species only, with spore-cases sessile, bursting horizontally, not vertically, the ring broad, sub-oblique, and nearly complete, the sori dorsal and oligocarpous, covered by umbonate-hemispherical indusia, which are petiole or affixed by a central stalk. *Gleicheniaceæ*, with the ring complete transverse, either truly or obliquely horizontal, the spore-cases globose-pyriform, forming oligocarpous sori, i.e. sori consisting of but few

spore-cases (two or four to ten or twelve) situated at the back of the frond, sessile or nearly so, and bursting vertically; fronds rigid and opaque, and usually dichotomously-branched. *Trichomanineæ*, with the ring resembling that of the *Gleicheniaceæ*, but the spore-cases lenticular, clustered on an often exerted receptacle, which is a prolongation of the vein beyond the ordinary margin of the frond, so that the sori become extrorse marginal or projected outwards, as well as opening outwardly; fronds pellucid-membranaceous. *Schizariaceæ*, with the ring horizontal or transverse, situated quite at the apex of the oval spore-case, which is, in consequence, said to be radiate-striate at the apex; the spore-case also sometimes resupinate, or turned upside down, so that the true apex is below; habit sometimes scandent. *Ceratopteridaceæ*, one or two aquatic species, the spore-cases sometimes furnished with a very rudimentary ring, reduced, as in *Osmundineæ*, to a few parallel strise, sometimes furnished with a very broad and more lengthened ring; spores bluntly triangular, marked with three series of concentric lines. *Osmundinaæ*, with the spore-cases two-valved, bursting vertically at the apex, the ring very rudimentary, reduced to a few parallel vertical strise on one side near the apex of the spore-case. In all but the last of these groups, the spore-cases are not valvate, and consequently, when they open for the liberation of the spores, they burst partially or irregularly, and do not split at the top in two equal divisions, as occurs in the *Osmundineæ*.

These primary and secondary groups will be more readily comparable in the following summary:—

#### Spore-cases ringless.

1. OPHIOGLOSSACEÆ—Fructifications marginal on rachiform fronds.
2. MARATTIACEÆ—Fructifications dorsal on flat leafy fronds.
  - § *Marattineæ*—Sori oblong, distinct, longitudinally biserial.
  - § *Kaulfussineæ*—Sori circular, distinct; spore-cases annularly concrete.
  - § *Danettineæ*—Sori connate throughout.

#### Spore-cases having a jointed ring.

3. POLYPODIACEÆ—Spore-cases not valvate; rarely somewhat two-valved vertically.
  - § *Polypodiaceæ*—Ring vertical, nearly complete; spore-cases usually stalked, gibbous; receptacles superficial or immersed.
  - § *Cyatheaceæ*—Ring obliquely vertical, nearly complete, narrow; spore-cases crowded, sessile or subsessile, oblique-laterally compressed; receptacles elevated.
  - § *Matoniaceæ*—Ring sub-oblique, nearly complete, broad; spore-cases few, sessile, gibbous; sori oligocarpous.
  - § *Gleicheniaceæ*—Ring zonal, horizontally or obliquely transverse, complete; spore-cases sessile or subsessile, ver-

tically compressed; sori dorsal; fronds rigid.

9 *Trichomanineæ*.—Ring and spore-cases as in *Gleichenineæ*; sori extrorse-marginal; fronds pellucid.

9 *Schizetineæ*.—Ring apical, complete, horizontally transverse; spore-cases sessile or subsessile, oval, crowned by the convergent strise of the ring, sometimes resupinate.

9 *Ceratopteridineæ*.—Ring rudimentary or more or less incomplete, very broad, flat, obliquely-vertical; spore-cases sessile, globose.

9 *Osmundineæ*.—Spore-cases vertically two-valved; ring rudimentary, transverse.

The *Polypodineæ* are further divided into lesser groups characterised by the form, position, and vestiture of the sori. There is little difference of opinion amongst pteridologists as to the three principal divisions, but a good deal of diversity as to the value of the minor ones. [T. M.]

**FILICOLOGY.** That part of Botany which treats of Ferns.

**FILICALES.** That alliance of Acrogens to which the Ferns belong.

**FILIFORM, FILIFORMIS.** Slender, like a thread.

**FILIPENDULE.** (Fr.) *Spiraea Filipendula*.

**FIMBRIA.** A fringe. An elastic toothed membrane, situated beneath the operculum in urn-mosses.

**FIMBRIATE.** Having the margin bordered by long slender processes, forming a fringe.

**FIMBRIATO-LACINIATE.** Having the edge cut up into divisions which are fimbriated.

**FIMBRILIFEROUS.** Bearing many little fringes, as the receptacle of some composites.

**FIMBRISTYLIS.** A genus of cyperaceous plants, belonging to the tribe *Scirpeæ*, having the inflorescence in spikes, solitary, in pairs, or in crowded heads, many-flowered; scales imbricated allround, the lower larger, one or two of them barren; style compressed and fringed, its base enlarged, adhering to the ovary. This genus embraces nearly 200 species, which have a wide geographical range, though most of them are natives of rather warm countries. [D. M.]

**FIMETARIOUS.** Growing on or amidst dung.

**FINCKEA.** A name given to a section (originally proposed as a genus) of the genus *Griesebachia* in *Ericaceæ*. The two South African species included in it differ from other *Griesebachia* in having the capsule usually unilocular and one-seeded. The corolla is ovate-tubulous, not urceolate or campanulate, as in others of the genus. [J. Dr.]

**FINGERED.** The same as Digitate.

**FINGERHUTHIA.** A genus of grasses belonging to the tribe *Phalarideæ*. Glumes two, equal, with bristly points, keeled and membranaceous; lower flowers fertile, as long as the glumes; pales rigid, the lower rather the longest, keeled, with a short bristle at the point, five to seven nerved, the upper shorter and slightly compressed; stamens three, with bearded anthers; styles two; upper flowers imperfect. Only two species are described, both of which are natives of South Africa. [D. M.]

**FIN HOUSSY.** (Fr.) *Trifolium repens*.

**FINLAYSONIA.** A genus of *Asclepiadaceæ*, containing a single species, native of India. It is a twining glabrous plant, yielding a milky juice, and having opposite obovate leaves, and numerous small flowers arranged in interpetiolar corymbis. The calyx is small, five-cleft; and the corolla rotate. The staminal crown, which rises from the throat consists of five delicate white slightly converging threads, each bent back at the apex so as to form a small hook; the stamens are distinct, with short filaments, and large anthers adhering to the stigma; and the divaricate follicles contain numerous large flat obovate seeds with a few silky fibres. [W. C.]

**FINOCCHIO.** *Feniculum dulce*. —, *ASSES*. *Feniculum piperitum*.

**FIORIN.** *Agrostis stolonifera*, and *Agrostis alba*.

**FIORIN DES ANGLAIS.** (Fr.) *Agrostis stolonifera*.

**FIR.** A general name for the trees referred to the coniferous genera *Pinus*, *Abies*, *Larix*, &c. —, **BALM OF GILEAD.** *Abies balsamea*. —, **HEMLOCK SPRUCE.** *Abies canadensis*. —, **PARASOL.** *Scadopytis verticillata*. —, **PLUM.** *Prumnopitys elegans*. —, **SCOTCH.** *Pinus sylvestris*. —, **SILVER.** *Abies pertinata*; also a general name for the species sometimes referred to *Picea*. —, **SPRUCE.** *Abies excelsa*; also a general name for the species of true *Abies*.

**FIREWEED.** An American name for *Erechtites hieracifolia*.

**FIR-RAPES.** Lindley's name for the *Monotropaceæ*.

**FIRS, JOINT.** A name proposed by Lindley for the order *Gnetaceæ*.

**FISCHERIA.** A genus of *Asclepiadaceæ*, containing about ten species from the West Indies and Central America. They are twining hairy shrubs, with opposite cordate leaves, and many flowers in racemes on long interpetiolar peduncles, which thicken upwards and are scarred by the deciduous pedicels. The calyx is five-parted; the corolla is rotate and five-cleft, the divisions having a curled indentation at their apices; the staminal crown is simple or double; the pentagonal stigma

covers the pollen-masses; and the follicles are ovoid and fleshy. [W. C.]

**FISH-POISON.** *Lepidium Piscidium*. —, JAMAICA. *Piscidia Erythrina*.

**FISSENIA** (correctly, **KISSENIA**). A genus of *Loasaceæ*, found in Arabia and in South and Central Africa, the only representative of the family in the eastern hemisphere. It differs from other genera in having a three-celled fruit, with one seed in each cell. The only species, *F. spathulata*, is a branching bush with straw-

*Fisselia spathulata*.

coloured stems, alternate stalked lobed leaves not unlike those of the gooseberry but larger, and pale green flowers four to six together at the ends of the twigs; the flowers have ten petals, five large and rounded, and five small and narrow, very numerous stamens, and three styles. The little ten-ribbed fruits or nuts crowned with the five long narrow calyx lobes, look like miniature shuttlecocks. [A. A. B.]

**FISSICALYX.** A tree from Venezuela, with pinnate leaves and terminal panicles of yellow flowers, forming a genus of *Leguminosæ* of the tribe *Dalbergiæ*, distinguished from all others by the irregularly split calyx; by the anthers opening in terminal pores; and by the fruit being surrounded by a broad membranous wing proceeding from the centre instead of the edges of the valves, thus giving the fruit the appearance of that of *Guaiacum*.

**FISSIDENS.** A pretty genus of mosses, containing both acrocarpous and cladocarpous species, and at once distinguished by their peculiar habit arising from the flat broad-keeled two-ranked leaves with a sheathing base. The peristome is single, and the sixteen teeth of which it is composed deeply cleft. The species grow on banks, on stiff soil, or near watercourses, and vary from a line to two inches in length. They occur in both hemispheres and in various climates, the species of very distant countries being frequently identical. The shoots sometimes bear reproductive bodies

at their apex, distinct from the proper fruit. These are occasionally close to the male organs. [M. J. B.]

**FISSIDENTEÆ.** A natural order of mosses which are remarkable for their peristome being like that of *Dicranum* or almost rudimentary, accompanied by a totally different habit due to the flat broad-keeled sheathing leaves. *Fissidens* has already been noticed. *Drepanophyllum*, from which the order is sometimes called *Drepanophylloïdæ*, is a magnificent moss abounding in Cayenne, with a tawny tint, the habit of a *Jungfermannia*, and a nearly naked peristome. The tips of the male plants bear, in close connection with the antheridia, tufts of jointed fusiform purplish gemmæ. *Cymontrium* is an aquatic genus, and has irregular unequally split often truncate teeth without any central line, and a nitraform veil. The species grow in running water, and one only has at present been found in Europe. [M. J. B.]

**FISSIPAROUS.** Propagating by a subdivision of the anterior of a cell into two or more other cells, by the production of a membranous partition or septum, from the lining of the mother cell.

**FISSES.** Divided *halfway*; usually into a determinate number of segments. We say *bifidus*, split in two; *trifidus*, in three, and so on; or *multifidus*, when the segments are very numerous.

**FISTULAR, FISTULOUS.** This is said of a cylindrical or terete body which is hollow, but closed at each end, as the leaves and stems of the onion.

**FISTULINA.** A genus of pore bearing *Fungi*, sometimes wrongly associated with *Umbonium*. It is distinguished from the fleshy *Polypori* by the free tubes which are at first closed and look like little stellate pink or cream-coloured pimples. *F. hepatica*, our only species, grows on the trunks of old oaks, and acquires sometimes a very large size. When divided it looks like beet-root, and drips with red juice. It is not unwholesome, but in our opinion not a pleasant article of food, however disguised with lemon juice, cayenne pepper, or other condiments. [M. J. B.]

**FITCH.** The Vetch or Tare.

**FITCHIA.** A genus of arborescent elchorraceous *Compositæ* founded on a single species, *F. nutans*, from Elizabeth Island in the South Pacific. It is a noble plant nearly related to *Rea*, and has thick woody stems, opposite broad ovate-cordate leaves, and large terminal drooping heads of flowers, hanging by longish stalks. The involucre is broadly campanulate, composed of about three series of orbicular scales, which enclose numerous ligulate male flowers; the females are unknown. The filaments and style are very much exserted. The achenes are compressed, clothed with silky hairs, and terminated by a pair of elongated hairy setæ. It is named in compliment to Mr. W. Fitch, a

clever botanical artist, by whom the drawings of the plants figured in this work have been executed. [T. M.]

#### FITWEED. *Bryngium fatidum*.

**FITZROYA.** A genus of coniferous or cone-bearing plants belonging to the sub-order *Oupressimæ*. It was named by Dr. Hooker in honour of Captain Fitzroy, who first discovered the tree. The fruit is in small starlike cones which consist of nine scales, three in each whorl: the lower three and upper three are barren, while the intermediate three are fertile, and bear each three winged seeds. The leaves are in threes, sometimes twos or fours, ovate-oblong, flat, without stalks. There is one species, *F. patagonica*, an evergreen tree growing to the height of 100 feet, with slender spreading branches which curve at the extremities. The tree, which is found on the mountains of Patagonia, bears the ordinary winters of Britain. [J. H. B.]

**FIVE-FINGERS.** *Potentilla reptans* and *canadensis*.

**FLABELLATUS, FLABELLIFORMIS.** Fan-shaped.

**FLACCID.** Wilted, or relaxed in consequence of the loss of moisture.

**FLACOURTIACEÆ.** (*Bixacæ*, *Bixads*.) A natural order of thalamifloral dicotyledons belonging to Lindley's violal alliance of hypogynous Exogens. They are shrubs or small trees with alternate leaves having no stipules, often marked with round transparent dots. Sepals and petals four to seven, the latter sometimes wanting; stamens same number as petals or a multiple thereof; ovules attached to parietal placentas. Fruit one-celled, either fleshy and indehiscent, or a four to five valved capsule containing pulp, in which numerous albuminous seeds are enveloped. The plants are natives of the East and West Indies, and of Africa. Two or three species are found at the Cape of Good Hope, and one or two in New Zealand. Some of the plants are bitter and astringent; others yield edible fruits. Arnotto is the red pulp enclosing the seed of *Bixa Orellana*, and it is used as a dye, for staining cheese, and in the manufacture of chocolate. Some *Flacourtiæ* yield subacid fruit. There are some two dozen genera, including *Flacourtia*, *Mayna*, *Bixa*, *Azara*, *Erythropspermum*; and about 150 species. Bentham and Hooker include *Pangliaceæ*. [J. H. B.]

**FLACOURTIA.** The typical genus of *Flacourtiaceæ*, characterised by having a succulent fruit and several stigmas. It has distinct male and female apetalous flowers, usually borne on different plants; the males have a great number of stamens crowded together upon the dilated receptacle, but not surrounded by glands like those of *Rourea*; the females have an ovary crowned with from four to nine narrow radiating stigmas. The species are mostly shrubs, but some few, however, attain a height of twenty or thirty feet, and nearly

all are armed with thorns. They are found in tropical Asia, Africa, and America.

The young shoots and leaves of *F. cataphracta* are used medicinally by the native Indian doctors, who prescribe them in diarrhoea, and also as an infusion to remove hoarseness; they are astringent and stomachic. *F. Ramontchi* is a small tree, native of Madagascar and India, producing a dark violet or black fruit about the size and shape of a plum, and having a sharp but sweet taste. *F. sepiaria*, a bushy shrub, is used in some parts of India for making hedges, its spiny nature rendering it peculiarly suitable for that purpose. The fruits are sold in the markets, and, like those of *F. Ramontchi* and *sapida*, have a pleasant subacid flavour when perfectly ripe, but the unripe fruit is extremely astringent. The Indian doctors use a Jiliment made of the bark in cases of gout, and an infusion of it as a cure for snake-bites. [A. S.]

**FLAG.** *Iris*. —, CAT-TAIL. An American name for *Typha*. —, CORN. *Gladiolus*. —, SWEET. *Acorus Calamus*. —, YELLOW. *Iris Pseud-acorus*.

**FLAGELLARIA.** A genus of *Commely-nacæ*, but referred to *Juncacæ* by some authors. Natives of India and Australia, with lanceolate leaves, sheathing the stem at the base, and terminating in a spiral tendril; flowers paniculate, bracteolate, the perianth six-cleft coloured persistent, with the three inner segments largest; stamens six, with simple glabrous filaments, fruit a pea-like drupe containing a single seed. [J. T. S.]

**FLAGELLIFORM.** Long, taper, and supple, like the thong of a whip, as the runners of many plants.

**FLAGELLUM.** A twig, or small branch; also a runner like that of the strawberry.

**FLAMBE.** (Fr.) *Iris Pseud-Acorus*. — **PETITE.** *Iris pumila*.

**FLAMBOYANTE.** (Fr.) *Tulipa turcica*; also *Potinciana regia*.

**FLAME-COLOURED, FLAMMEUS.** Very lively scarlet; fiery red.

**FLAME TREE.** *Brachychiton acerifolium*.

**FLAVEDO** Yellowness; a disease in plants in which the green parts assume that colour.

**FLAVESCENS, FLAVIDUS, FLAVUS.** A pure pale yellow.

**FLAVO-VIRENS.** Green, much stained with yellow.

**FLAVERIA.** An herbaceous biennial composite, distinguished by having the common involucre imbricated with unequal scales, and the partial of two to five leaves containing as many florets, a naked receptacle, and no pappus. *F. Contrayerba* is a native of Peru, and derives its name from its being used to dye yellow. It grows to the height of eighteen inches,

with lanceolate serrated sharp-pointed leaves, and terminal heads of yellow flowers. [O. A. J.]

**FLAX.** The common name for *Linum*; also the fibre obtained from the stems of *Linum usitatissimum*. — FALSE. An American name for *Camelina*. — NEW ZEALAND. *Phormium tenax*. — TOAD. *Linaria*.

**FLAX-BUSH.** *Phormium tenax*.

**FLAX-SEED.** *Radiola*.

**FLAX-STAR.** *Lysimachia Linum-stellatum*.

**FLAXWORTS.** A name for the order *Linaceæ*.

**FLEABANE.** *Conyza*; also *Pulicaria vulgaris* and *dysenterica*; also *Euphorbia ruscifolia*, *gracilens*, and *acris*. — AFFRICAN. *Tarcomanthus*. — MARSH. *Plicatula*.

**FLEA-SEED.** The seed of *Plantago Psyllium*.

**FLEAU DES PRÉS.** (Fr.) *Phleum pratense*.

**FLEAWORT.** *Pulicaria vulgaris*; also *Plantago Psyllium*.

**FLÉCHIERE.** (Fr.) *Sagittaria sagittifolia*.

**FLEMINGIA.** A genus of erect, prostrate, or sometimes twining plants of the pea family, and nearly allied to *Rhynchosia*, but differing in having a turgid and two-seeded, instead of a flattened and many-seeded pod. Most of the twenty known species are found in India, a few extending to the northern and eastern portions of Australia, and one, *F. betulifolia*, occurring in W. Africa. The stems are furnished with simple or trifoliate stalked leaves, often having glandular dots; in some species the stipules are large and chaffy. The small vetch-like flowers are purple, white with pink lines, or yellow, and disposed in axillary compound racemes or panicles.

One of the most elegant of them, *F. strobilifera*, is remarkable for its drooping catkin-like racemes, furnished with large, pale yellow kidney-shaped bracts, each of which encloses a fascicle of white flowers marked with pink lines. The leaves are simple, ovate and acute, and vary much in size. The plant has been in cultivation.

A beautiful purple-flowered species, *F. vestita*, is cultivated in many parts of N. W. India for the sake of its edible tuberous roots, which are nearly elliptical, and about an inch long. The plant is prostrate, with weak stems, and hairy clover-like leaves, formed of rounded hairy leaflets. The purple blossoms are larger than in any other of the genus, and are remarkable for being placed two or three together on the apex of a slender axillary flower stalk, those of the other species being disposed in racemes. The genus bears the name of Dr. J. Fleming, an Indian botanist. [A. A. B.]

**FLÉOLE.** (Fr.) *Phleum pratense*.

**FLESH** of vegetable bodies. The soft parts.

**FLEUR DE COUCOU.** (Fr.) *Lychnis Flos-cuculi*; also *Primula veris*, and *Narcissus Pseudo-Narcissus*. — DE GRAPAUD. *Stapelia variegata*. — DES DAMES. *Heliotropium peruvianum*. — DE JUPITEIL. *Lychnis Flos Jovis*. — DE LA PASSION. *Passiflora*. — DE LA TRINITÉ. *Viola tricolor*. — DE LIS. *Phalangium Lilago*; also *Iris germanica* and other European species. The Fleur de lis representing the Iris is the emblem of France, and was called by old English authors Flower de Luce. — DE MIEL. *Melanthus major*. — D'ORET D'ARGENT. *Lonicera confusa*. — DE PAON. *Poncinia pulcherrima*. — DE PAQUES. *Bellis perennis*. — DE PARADIS. *F. cum pulcherrima*. — DE QUATRE HEURES. *Mirabilis dichotoma*. — DES VEUVES. *Scabiosa atropurpurea*. — DU DIABLE. *Iris sanguinea*. — D'UNE HEURE. *Hibiscus venecianus* and others. — DU GRAND-SEIGNEUR. *Amorpha moschata*. — DU SOLEIL. *Melanthus amarus*. — EN CASQUE. *Aconitum Napellus*.

**FLEURYA.** A genus of *Urticaceæ* composed of a number of annual or perennial weeds, found in the tropics of both hemispheres. They are much like common nettles in appearance, and some of the species are furnished with stings, but they may be readily distinguished from them by their alternate (not opposite) leaves, as well as by the narrow bilid stipules which accompany them. From other allied genera they differ in their little, oblong or rounded and compressed achenes having concave depressions on both surfaces. [A. A. B.]

**FLEXUOSE.** Zig-zag; having a wavy direction, gently bending alternately inwards and outwards.

**FLINDERIA.** A genus of *Cedrelaceæ*, having a calyx of five short teeth; five

*Flindersia australis*.

white, ovate, plane petals, slightly hairy on the exterior; ten stamens of which only five are fertile, the alternate ones being sterile; and a simple erect obtusely five-angled style, with a peltate five-lobed

stigma. The capsule is woody, oblong, obtuse, five-valved, the exterior thickly covered with sharp-pointed tubercles. They are lofty trees, having alternate pinnate leaves; found in New South Wales and the Moluccas. The natives of these islands use the rough tuberculated fruit as rasps in preparing roots &c. for food. [L. H.]

**FLIX-WEED.** *Sisymbrium Sophia.*

**FLOCCI.** Woolly threads, found mixed with sporules in fungi; also any wool-like hairs.

**FLOCCOSE.** Covered with close woolly hairs, which fall away in little tufts.

**FLORAL.** Of or belonging to the flower. — **ENVELOPES.** The calyx and corolla, one or both.

**FLOR DE AROMA.** *Acacia Farnesiana.* — **DE ISABEL.** *Banksia spectabilis.* — **DE JESU'S.** *Lasia acuminata.* — **DE MAYO.** *Lasia nupalis.*

**FLORESTINA.** A genus of Mexican composite herbaceous plants, with the habit of *Shorea*, to which they were formerly referred. They are covered with small appressed white hairs, and have entire or pedately divided leaves, and flowers borne in loose corymbs surrounded by an involucre of eight short bracts. The corollas have all a short tube, and a whitish-purple limb divided into five segments. The achenes are somewhat four-cornered, surmounted by a pappus of eight or twelve membranous scales. [M. T. M.]

**FLORETS.** When many small flowers are collected in clusters or heads, each flower is called a floret. The *florets of the disk* are those which occupy the centre of the head of a composite; while *florets of the ray* occupy the circumference.

**FLORIDE.** A name given to the rose-spired *Akai*, in consequence of many of them exhibiting the rosy tints of flowers. They are now more generally known as *Rhodoperma*. [M. J. B.]

**FLORIFER.** Flower-bearing.

**FLORIPAROUS.** Producing flowers also a mossy consisting in the production of other fl. — Instead of fruit

**FLORIPONDIO.** *Datura sanguinea.*

**FLORKEA.** A North American annual herb, referred to the limnanthes division of *Tropaeaceae*. It is a marsh plant, with slender decumbent stems, and alternate pinnately-parted leaves, bearing solitary small white flowers in their axils. It is distinguished from *Limnanthes* chiefly by its having trimerous instead of pentamerous flowers. [T. M.]

**FLORI'S.** In composition = flowered. thus *uniflorus* is one-flowered; *biflorus*, two-flowered; *triflorus*, three-flowered; *multiflorus*, many-flowered, &c.

**FLOS.** A flower. — **COMPOSITUS.** An old name for the capitulum.

**FLOS ADONIS.** *Adonis autumnalis.* — **AERIS.** *Aerides Arachnites.* — **CARDINALIS.** *Quamoclit vulgaris.* — **CUCULI.** *Curdemine pratensis*; also *Lychnis Flos-cuculi.* — **GLOBOSUS.** *Gomphrena globosa.* — **JOVIS.** *Lychnis Flos Jovis.* — **MARTINI.** *Aistrimeria Flos Martini.* — **PASSIONIS.** *Passiflora cœrulea* and others. — **SOLIS.** *Helianthus annuus*; also *Helianthemum vulgare.* — **SUSANNE.** *Platanthera Susanna.* — **TRINITATIS.** *Viola tricolor.*

**FLOSCOPA.** A genus of *Commelynaceae* more usually known under the name of *Dithyrocarpus*, and distinguished by having nearly regular flowers, with six stamens, all fertile, with parallel anther-cells; and a two-celled ovary and capsule, with one ovule and seed in each cell. There are but very few species, natives of the tropical regions both of the new and the old world. The most common species, *F. pinnulata*, is abundant in Asia, and is also found in South Africa and Brazil. It is a herb of two or three feet in height, with acuminate leaves, and a dense hirsute terminal panicle of small blue flowers.

**FLOSCULI** (adj. **FLOSCULOSE**). The same as Florets.

**FLOTOVIA.** A genus of spiny S. American bushes belonging to the *Compositae*, and nearly related to *Barnadesia*, from which it differs in its regularly five-parted, not two-lipped corollas. The numerous florets of the flower-heads, and the insertion of the stamens on the middle of the corolla tube, are the characters which separate the genus from its other allies. Upwards of twenty species are known, the greater portion found in Brazil, a few in the Peruvian Andes, and one or two in Chili. For the most part they are bushes of four to six feet, with alternate leaves, accompanied by two straight slender spines. The pink flower-heads in some are solitary at the ends of the branches, but more commonly numerous and small; the silky achenes are crowned with a pappus of one series of beautiful feathery awns. *F. argentea*, pretty Andean species, is by some referred to *Dasyphyllum*. [A. A. B.]

**FLOURENSIA.** A genus of resiniferous composite shrubs found in New Mexico and Chili, and nearly allied to *Helianthus*, differing chiefly in the tongue like branches of the style, which are obtuse and not tipped with an awl-shaped appendage. The leaves are usually covered with a gummy exudation. The yellow rayed flower-heads are usually large and solitary or two to three together at the ends of the twigs. The most handsome species is *F. thurifera*, which grows to a bush of four six feet in Chili, and has its twigs well as its broadly lance-shaped leaves covered with a resinous substance, which is collected and burnt as incense in the churches; its fine yellow flower-heads are single at the ends of the twigs, and more than two inches across. The Chilians call

the plant Maravilla, or Maravilla del Campo. Four species are known. [A. A. B.]

**FLOUVE.** (Fr.) *Anthoxanthum*. — **DES BRESSANTS.** *Anthoxanthum odoratum*.

**FLOWER.** That assemblage of organs in a plant, of which the stamens, or pistils, or both, form part.

**FLOWER DE LUCE.** An old English name for the common species of *Iris* — *germanica*, *florentina*, &c.

**FLOWER OF CRETE.** *Mesembryanthemum Tripolium*.

**FLOWER OF JOVE.** *Lychnis Flos Jovis*.

**FLOWER-FENCE.** *Punciana*. —, **BAIBADOS.** *Poncianum pancheriana*. —, **BASTARD.** *Adenanthera*.

**FLOWER-GENTLE.** *Amaranthus*.

**FLUELIN.** *Linaria Elatine* and *spuria*; also *Veronica officinalis*.

**FLUGEA.** A genus of *Euphorbiaceæ* nearly related to *Phyllanthus*, from which it may be recognised by the sterile flowers having three stamens surrounding a rudimentary ovary, there being no rudimentary ovary in those of *Phyllanthus*. The genus consists of several much branched smooth and entire-leaved bushes found in most tropical countries of the eastern hemisphere. The leaves are obovate or ovate. The flowers, sterile and fertile on different plants, are minute, green, and disposed in fascicles or cymes in the axils of the leaves. The fruits are dry capsules or berries about the size of a pea or smaller. The bark of *F. viosus*, according to Roxburgh, is strongly astringent, and possesses the property of intoxicating fish when thrown in the water, thus rendering them easily caught. The white berries of *F. lucopinus* in India, and *F. abyssinica* in Eastern tropical Africa, are eaten by the natives. A Chinese species, *F. suffruticosa*, has long been known as *Gebura suffruticosa*. [A. A. B.]

**FLUITANS.** Floating upon the surface of water.

**FLUVIAL, FLUVIATILE.** Of or belonging to the water.

**FLUTEAU.** (Fr.) *Alisma Plantago*.

**FLUVIATES.** A natural order of monocotyledonous aquatics established by Ventenat. The plants are now included in *Najas*; which see. [J. H. B.]

**FLY-AGARIC.** The common name of *Agaricus muscarius*, a splendid scarlet species studded with white or yellow warts, which is common in birch woods, and is used to make a decoction for destroying flies. Its narcotic properties are so strong that in some countries it is employed, mixed with the juice of cranberries, to produce intoxication, the dry plant being more efficacious for this purpose than the fresh. The effects are some-

what different from those of other narcotics, being characterised by extreme stimulation of the muscles. The nervous system is at times excited to such a degree as to produce the most ludicrous actions. It is a curious fact that the urine of persons who have partaken of the fungus acquires the same narcotic properties; or, in other words, that the narcotic principle, like some other substances, passes through the urine without change. (See E. A. Parkes on the *Composition of Urine*, 1860.) In excess it is doubtless a dangerous poison, and we have known temporary intoxication arise from its accidental use. [M. J. B.]

**FLY-POISON.** *Amianthium muscivorticum*.

**FLY-TRAP.** *Apocynum androsaemifolium*. —, **VENUSS.** *Dionaea muscipula*.

**FLY-WORT.** A name applied to those species of *Catastemum* formerly called *Myanthus*.

**FEMINEUS.** Female, that is, bearing pistils only.

**FENICULUM.** A genus of umbelliferous plants, with finely dissected leaves, no involucre, and yellow flowers. It is distinguished from *Anethum*, to which it is very closely allied, by the fruits being somewhat compressed from side to side, and not from back to front. *F. vulgare*, the common Fennel, is a native of temperate Europe and Western Asia; in this country it is usually found in dry chalky soil, at no great distance from the sea. The Sweet Fennel, *F. dulce*, is by some considered as only a variety of the preceding; but it differs in being a smaller plant, in the stem being compressed at the base, not round, in the smaller number of rays to the umbel, in the greater size of the fruit, in flowering earlier, &c. It is grown in this country as a potherb and for garnishing; its fruit supplies an aromatic oil, which is carminative like dill. [M. T. M.]

**FENUM GRÆCUM.** *Trigonella Fœnum græcum*, so called because formerly made into hay in Greece. It was also cultivated by the Romans, and is still occasionally employed in the agriculture of the south of Europe. The plant and seeds are strongly scented, with the new hay-like odour of coumarin.

**FETIDIA.** A genus of shrubby plants doubtfully placed in *Myrtaceæ*, the leaves being alternate and without dots, and the flowers destitute of petals. The three known species are natives of the Mauritius and Madagascar, attaining a height of thirty or forty feet, the ash-coloured branches furnished at their extremities with smooth entire, ovate or lance-shaped leaves. The flowers are axillary and solitary, and have a three or four-sided calyx tube, with a border of four triangular lobes, and very numerous stamens. The fruits are woody, four-sided, four-celled, somewhat top-shaped nuts. *F. mauritiana*, known as 'Le Bois puant' in the Mauritius,

furnishes good furniture wood. According to Roxburgh, the bark is very tough, red within, bitter and astringent. It is used by woodmen for banding up the wood, instead of cord. The common appellation of Stinkwood has no doubt suggested the name of the genus. [A. A. B.]

**FOG-FRUIT.** An American name for *Lippia nodiflora*.

**FOLIACEOUS.** Having the texture or form of a leaf, as the branches of *Xylophylla*.

**FOLIA MALABATHRI.** The aromatic dried leaves of *Cannamomum nitidum*.

**FOLIAR.** Inserted upon, or proceeding from the leaf; thus a *cirrus foliaris* is a tendril growing from a leaf.

**FOLIATION.** The act of leafing.

**FOLIATE.** Clothed with leaves.

**FOLLICULARES.** A suborder of plants belonging to the *Proteaceae*, and referred by DeCandolle to the monocotyledonous dicotyledons. They are distinguished by their coriaceous or woody follicles, which contain one or many seeds. The general characters of the order are given under *PROTEACEAE*. The follicular division contains such genera as *Grevillea*, *Hakea*, *Lambertia*, *Rhopala*, *Krugia*, *Telopoa*, *Lomatia*, *Banksia*, and *Dryandra*. [J. H. B.]

**FOLLIPAROUS.** Producing leaves only, as leaf-buds.

**FOLIOLE** (adj. **FOLIOLATE**). A leaflet; the secondary divisions of a compound leaf.

**FOLIOSE.** Covered closely with leaves.

**FOLLE-AVOINE.** (Fr.) *Avena sativa*.

**FOLLETTE.** (Fr.) *Atriplex hortensis*.

**FOLLICLE.** A kind of fruit, consisting of a single carpel, dehiscing by the ventral suture only, as in *Delphinium*, *Asclepias*, *Apocynum*, &c.

**FONTANESIA.** A Syrian shrub of the olive family, named in honour of M. Desfontaines, an eminent French botanist. It has lance-shaped leaves, ciliated at the margins; and white clustered flowers with a persistent four-cleft calyx, and four petals united into pairs at the base by the adhesion of the two stamens. The ovary is two to three-celled, with two suspended ovules, the style short, the stigma cleft into two threadlike divisions. The capsule is thin, notched, indehiscent, surmounted by the stigma, and having a membranous margin. [M. T. M.]

**FONTINALEI, FONTINALIS.** A small section and genus of pleurocarpous mosses, distinguished by their aquatic habit, the nearly sessile capsule immersed in the perichaetal leaves, and the cancellated inner peristome. The principal genus, *Fontinalis*, contains a few species confined to temperate regions of the northern hemisphere. The leaves are curiously compressed, so

that the stems have a triquetrous outline. There is, however, no nerve as in the *Drepanophyllet*, and they are frequently split down the middle, each division looking like a separate leaf. *F. antipyretica* is common about millwheels, on stones, roots, &c., in running streams; and does not fructify unless the plant is exposed or the ends of the branches come up to the surface. The dried plant is used by the Laplanders to stuff the space between the chimneys and the wall, to prevent fire, as it does not easily ignite. *Fontinalis* has a unistriform calyptra, but in the neighbouring genus *Dicelasma* the calyptra is dimidiate, while the capsules are more exerted. [M. J. B.]

**FONTINALIS, FONTANUS.** Growing in or near a spring of water.

**FOOL'S-STONES.** *Orchis mascula* and *Morio*.

**FORAMEN.** An aperture. The foramen of an ovule is an aperture through the integuments, allowing the passage of the pollen tubes to the nucleus.

**FORAMINULE.** The ostiolum of certain fungals.

**FORBIDDEN FRUIT.** *Citrus Paradisi*. — (of London). A variety of the shaddock, *C. decurmana*. — (of Italy). The Pomme d'Adam, a variety of *C. Limetta*. — (of Paris). The sweet-skinned orange, a variety of *C. Aurantium*.

**FORCIPATE.** Forked, like a pair of pincers.

**FORGET-ME-NOT.** *Myosotis palustris*. —, **ANTARCTIC.** *Myosotidium nobile*.

**FORFICARIA graminifolia** is a terrestrial tuberous-rooted orchid of South Africa, with narrow, rigid, grassy leaves shorter than the stem, which is one to two feet high, and terminating in a loose raceme of eight to ten flowers, each supported by a short membranaceous bract. The upper sepal is boat-shaped, the two lateral ones larger, keeled and acute, the petals bristle-like and hairy, and the lip very short, fleshy and pubescent. There is only one species. [A. A. B.]

**FORNICATE.** Arched.

**FORNIX.** Little arched scales in the orifice of some flowers.

**FORRESTIA.** A genus of *Commelynnaceae* found in New Guinea. Herbs with elliptical lanceolate glabrous leaves having hairy sheaths, and red flowers in dense heads, with six stamens, the filaments of which are glabrous. [J. T. S.]

**FORSKALEA.** A genus of *Urticaceae*, found in various parts of Africa, the Mediterranean region, Arabia, and North-West India. It belongs to a small tribe characterised by the male flowers having but one stamen; and is distinguished from its near allies by its minute flowers being enclosed in a two or many-leaved involucre. The five known species are branching herbs, with tough somewhat woody stems clothed

with rigid stinging hairs, furnished with lance-shaped or ovate leaves, the little flowers densely packed in their axilla, males and females in the same involucre. *F. angustifolia* is said to be used in the Canary Islands to promote perspiration. The genus bears the name of M. P. Forskal, a botanist of the last century who wrote a flora of Egypt and Arabia Felix. [A. A. B.]

**FORSTERA.** A genus of *Stylidiaceæ* with a calyx of from three to six lobes; corolla white, campanulate, with a four to nine-lobed spreading limb; stamens and style united into a central erect column surmounting the ovary, having at its base two large erect subulate or lunate glands. The anthers, on the top of the column, are sessile, bursting transversely, the two halves hooded, the upper turned back; stigma two-lobed, feathery, and spreading in the female flowers; fruit a membranous capsule. The stems are simple or branched, two to three inches in height; the leaves more or less closely imbricated, alternate; the flowers monœcious or dioecious. Very remarkable Alpine plants, natives of Tasmania, New Zealand, and Fuegia. [R. H.]

**FORSYTHIA.** A genus of shrubs belonging to the *Oleaceæ*, having a four-parted calyx, a shallow bell-shaped four-cleft corolla, a two-lobed stigma, and capsular fruit. *F. viridissima* is very ornamental in March, with its numerous tufts of rather large pendulous bright greenish-yellow flowers, which grow two or three together from all parts of the rod-like branches. After these have faded, the slightly aromatic shining oblong lanceolate leaves make their appearance; they remain till late in autumn, turning yellow or purple before they fall off. The shrub then has somewhat the habit of a willow, but the stems are four-angled and studded with a number of large prominent buds. It is perfectly hardy. [O. A. J.]

**FORTUNÆA.** A genus of *Juglandaceæ* found in North China and Japan, and represented by a single species, *F. chinensis*, a smooth pinnate-leaved bush with the aspect of a *Sunach*, its leaves being composed of five to seven pairs of lance-shaped unequal-sided sharply serrated leaflets with an odd one. The branches are terminated by a cluster of slender drooping catkins of green male flowers somewhat like those of a willow, and a solitary cone-like and erect female catkin, made up of a number of hard-pointed bracts closely overlapping each other, and each bearing in its axil a little one-seeded, two-winged nut. According to Mr. Fortune, who first gathered the plant, and whose name it bears, the Chinese use the fruits to dye the black colour of their clothes. Its cone-like female catkins suffice to distinguish it from other *Geuca*. [A. A. B.]

**FORTUYNIA.** A genus of *Cruciferae* allied to *Raphanus*, but with the two lower cells of the pod empty, the two upper one-seeded and indehiscent. The pod is flattened, broadly winged, resembling that of

*Isatis*: indeed, the genus is founded on the *I. Garcini*, an eastern plant. [J. T. S.]

**FOTHERGILLA.** A genus of the witch-hazels, named in honour of Dr. Fothergill, a London physician and patron of Botany of the last century. The corolla is wanting; the stamens usually twenty-four in number, their filaments long and clubbed. The species are dwarf deciduous shrubs, natives of North America, having white and sweet-scented flowers. [G. D.]

**FOUGÈRE COMMUNE or GRANDE.** (Fr.) *Pteris aquilina*. — **FEMELLE.** *Athyrium Filix-femina*, also *Pteris aquilina*. — **FLEURIE.** *Osmunda regalis*. — **MALE.** *Lastrea Filix-mas*. — **MUSQUÉE.** *Myrrhis odorata*.

**FOUNTAIN TREE.** A popular name for *Cedrus Deodara*.

**FOURCROYA.** An amaryllidaceous genus closely related to *Agave*, and like it having long-lived massive stems, great fleshy leaves, and a very tall pyramidal terminal inflorescence produced after the lapse of many years. Herbert speaks of *F. longæva* as the most magnificent plant in the order, beyond all comparison: its stem forty feet high; its leaves less rigid and erect than in *Furca*; its inflorescence thirty feet high, the lower branches of the terminal pyramid twelve to fifteen feet long; and its white flowers innumerable. These flowers consist of a six-parted perianth, with regular nearly patent segments, subulate conniving filaments with versatile anthers, a straight hollow triangular style enlarged below, and a triangular fringed stigma. *F. gigantea* was formerly called *Agave fatida*, and is a smaller plant than the foregoing. The name *Koezlia regia* has been given in gardens to *F. Boedingeri*. The species occur in S. America, Mexico, W. Indies, and Madagascar. [T. M.]

**FOUR O'CLOCK FLOWER.** *Mirabilis dichotoma*.

**FOUROUCHE.** (Fr.) *Trifolium incarnatum*.

**FOUTEAU.** (Fr.) *Fagus sylvatica*.

**FOVEA** (adj. FOVEATE, dim. FOVEOLATE). A small excavation or pit: hence pitted.

**FOVEOLE.** The peritheciæ of certain fungi.

**FOVEOLARIA.** A genus of the *Styracæ* family, peculiar to Peru, and represented by a single species, *F. ferruginea*, so named because of the copious rusty down which clothes the branches, flower racemes, and under surface of the leaves. It is a tall bush, with alternate elliptical entire leaves; and the little white flowers, which are somewhat like those of the *Styracæ*, but smaller, are borne in axillary racemes, and have a five-toothed calyx, five oblong petals, and ten stamens adhering by their stalks into a tube so as to be monadelphous; this latter character being the chief dis-

(distinguishing feature. The fruits are little ovoid berries. [A. A. B.]

**FOVILLA.** The imaginary fluid or emanation which it was formerly thought that the pollen discharged when performing the act of fertilisation. The fluid actually contained in the pollen-grain.

**FOXGLOVE.** *Aconitum Vulparia*.

**FOX-CHOP.** *Mesembryanthemum vulpinum*.

**FOXGLOVE.** *Digitalis*. —, **DOWNY FALSE.** An American name for *Gerrardia flava*. —, **LADIES'.** *Verbascum Thapsus*.

**FOX-GRAPE.** *Vitis vulpina*, *Labrusca*, &c.

**FOX-TAIL.** *Lycopodium clavatum*.

**FRACID.** Of a pasty texture; between fleshy and pulpy.

**FRAGARIA.** A genus of *Rosaceæ*, distinguished by its ten-cleft calyx, its five petals, and its seeds inserted on a fleshy receptacle. This fleshy receptacle is the fruit known as the Strawberry. The name *Fragaria* is derived from *fragrans*—the fruit, as is well known, being peculiarly perfumed. The common name of Strawberry has been given, according to Sir Joseph Banks and others, on account of straw having been laid to prevent the fruit from getting soiled in wet weather.

There are several species, of which the principal are, *F. vesca*, to which belong the wood and Alpine varieties; *F. viridis*, the green; *F. elatior*, the Hautbois; *F. virginiana*, the Virginian or scarlet; *F. grandiflora*, the pine; and *F. chilensis*, the Chilean strawberry.

Previous to 1629, the date assigned to the introduction of the Scarlet Strawberry from Virginia, the Wood Strawberry must have been the sort generally gathered for sale in this country. 'Strawbery ripe,' together with 'Gode Peasecode,' and 'Cherry in the ryse,' were mentioned as some of the London cries by Liddate in a poem which he wrote, probably 400 years ago, or nearly, for he died in 1133. Peas must have been then cultivated for sale; strawberries may have been partially so, or they may have been chiefly gathered for the purpose where found growing in their wild state. But Hollinshed mentions the fact that Gloucester asked the Bishop of Ely for strawberries when contemplating the death of Hastings; and the circumstance has been dramatised by Shakespeare:—

'My lord of Ely, when I was last in Holborn,  
I saw good strawberries in your garden there.'

The palace and garden of the Bishop were situated in that part of London now called Ely Place; and the grounds sloping to the then open stream or rivulet of Holborn must have been well adapted for the growth of strawberries.

The green strawberry is a European

plant, but rarely met with. The fruit is small, very abundant, roundish; the flesh has a greenish tinge, solid, and juicy; and having somewhat of the pineapple flavour, something good might result from crossing it with other sorts.

The Hautbois is a native of England and the continent of Europe. It has not been found in a wild state so plentifully as the Wood or Alpine kinds. The cultivated varieties of this species sometimes bear most abundant crops; occasionally, however, the plants only produce sterile flowers, yet perhaps in another season the same plants again bear profusely, sterility being induced by circumstances which occasion a too rapid development of the parts of fructification, and their consequent imperfection. This led to the supposition that the Strawberry was a diocious plant; but it is not so, for the rudiments of stamens and pistils, more or less perfect, can always be detected. The Hautbois have plicated, rugose leaves, and the fruit has a musky flavour, which many persons greatly prefer.

The Virginian or Scarlet Strawberry has many varieties, of various forms, round, conical, and oblong, some of them sugary and mild, but most of the scarlets have a brisk acidity. The Old Scarlet still ranks amongst the earliest ripening sorts. Although it was almost the only scarlet known for nearly 200 years after its introduction, and a shy bearer, no attempts to change it by crossing appear to have been made till within the last fifty years. By accident some good varieties of it were obtained; now, by artificial crossing, they are exceedingly numerous. They cross readily amongst themselves, and likewise with the pine.

The Pine Strawberries have generally large flowers and fruit, with foliage of a darker green and thicker substance than that of the scarlets, and the leaves are not so sharply serrated. According to some authorities, the species is a native of Surinam, but the true Old Pine was doubtless obtained from Carolina. This sort is very much superior to many formerly cultivated under the denomination of Pine Strawberries, and which, although most abundant bearers, have been abandoned for new sorts that are both prolific and good in quality. Still, as regards richness of flavour, the true Old Pine or Carolina maintains its high character. Instead of being hollow and spongy, it is solid and juicy—so much so, that a basket of it may be detected among other sorts by its greater weight.

The Chili Strawberry is, as its name implies, a native of Chili; but Prof. Decaisne, in his splendid work, the *Jardin Frontier du Musée*, states that it is not confined to that part of South America, but has also been found on the western coast of North America, in California, and Oregon. The whole plant is covered with silky hairs, those on the scape and peduncles spreading horizontally. It is of vigorous growth where the climate is suitable for it;

but it was found rather tender for our severe winters, and it does not succeed in the climate of Paris, but in the south-west of France it thrives admirably. It was introduced to Marseilles from Chili, in 1712, by Frezier, a French officer of marine artillery. Five plants were all that survived the voyage; but in 1837 about 450 acres were occupied with this sort alone in the neighbourhood of Brest, where the mildness of the winters and moisture of the air are favourable to its growth. It was cultivated in this country by Philip Miller in 1727; afterwards it appears to have been lost, till reintroduced by the Horticultural Society. Though not itself adapted for our climate, very beneficial results have followed its reintroduction, for, by crossing, a very large variety called Wilmot's Superb was raised; and though this had too much of the tenderness of its parent, yet, by repeated crossing, others less tender and of better quality have been obtained, and among them that so extensively grown and so well known by the name of the British Queen, one of our most valuable sorts.

Formerly strawberries were chiefly carried to the London market by women in head-load baskets. These women came mostly from Wales and Shropshire, and returned after the fruit-gathering season was over. They often made two journeys from Isleworth or Twickenham to London, thus walking between thirty and forty miles daily, with heavy loads on their heads for half that distance. Such labour is now almost entirely done away with, and spring vans are employed for the conveyance of strawberries to the markets. [R. T.]

**FRAGILARIA.** A genus of *Diatomaceæ* in which the frustules adhere intimately to each other, so as to form long ribbon-like threads which are narrower at one end than the other, probably from the rupture of the thread in the centre. *F. hiemalis* is very common in little pools and runnels in early spring, and is always a pleasing microscopic object. [M. J. B.]

**FRAGON.** (Fr.) *Ruscus*.

**FRAISIER.** (Fr.) *Fragaria*. — À CHÂS-SIS. *Fragaria minor*. — BRESLINGE. *Fragaria collina*. — BUISSON. *Fragaria ciliolata*. — D'ANGLETTERRE. *Fragaria minor*. — DE L'INDE. *Fragaria indica*, sometimes called *Duchesnea fragarioides*. — DES BOIS. *Fragaria sylvestris*. — DE TOUS LES MOIS. *Fragaria semperflorens*. — FRESSANT. *Fragaria hortenensis*. — STÉRILE. *Potentilla Fragariastrum*. — DE VERSAILLES. *Fragaria monophylla*.

**FRAMBOISIER.** (Fr.) *Rubus Idæus*. — DU CANADA. *Rubus odoratus*.

**FRANCISCA.** A genus of Brazilian shrubs, included among the *Scrophulariaceæ*, and closely allied to *Brunfelsia*, from which it differs in the tube of the corolla being curved and dilated at its summit. There are several species in cultivation as stove plants, most of them

having very showy salver-shaped purple flowers. The root of *F. uniflora*, and, to a less extent, the leaves, are used in Brazil in syphilitic complaints; hence the plant is called by the Portuguese Vegetable Mercury. It is bitter, purgative, emetic, and is poisonous in large doses. [M. T. M.]

**FRANCISIA.** A name given by Endlicher to a supposed genus of *Chamaeliadaceæ*, founded upon a drawing of Ferdinand Baner's representing *Darwinia fascicularis*, its stamens by some error, possibly of the press, being described as twenty instead of ten. [J. Br.]

**FRANCOICEÆ** (*Francoideæ*.) A natural order of calycifloral Dicotyledons belonging to Lindley's Erical alliance of Hypogynous Exogens, referred by Benth and Hooker to *Saxifragaceæ*. Stemless herbs, with lobed or pinnate exstipulate leaves, and flowers in racemes; the calyx four-cleft; petals four, persistent; stamens about sixteen, attached to the lower part of the calyx, the alternate ones abortive. Ovary free, four-celled; ovules numerous; no style; stigma four-lobed. Fruit a four-valved capsule; seeds numerous, with a minute embryo and fleshy albumen. They are natives of Chili. Their qualities are astringent and slightly sedative. There are two genera, *Francoa* and *Tetilla*; and five species. [J. H. B.]

**FRANCOA.** A genus of perennial Chilian herbs, typical of the *Francoideæ*, having lyrate pinnatifid leaves which are nearly all radical, and flowers in simple or branched racemes, the pedicels bearing single flowers, and having a persistent bract at the base. The calyx is four-parted, the petals four, the stamens eight fertile alternating with eight sterile, and the ovary free, four-celled, with numerous ovules. There are four or five species. Their juice is said to be sedative, and the roots of some are used for dyeing black. [J. H. B.]

**FRANCEARIA.** A genus of *Compositæ Asteoideæ*, nearly allied to *Inula* and *Pulsatilla*, and containing only one species, *P. crispus*. This is an erect somewhat shrubby plant varying from subglabrous to densely tomentose, with short oblong semi-amplexicaul leaves, which are much waved at the margins. It is a native of Senegal and Egypt, and a form occurs in India. The flowers are in yellow terminal heads, and resemble those of *Pulsatilla*. [J. Br.]

**FRANGIPANE.** *Plumeria rubra*.

**FRANGIPANIER.** (Fr.) *Plumeria*.

**FRANKENIACEÆ.** (*Frankeniads*.) A natural order of thalamifloral dicotyledons belonging to Lindley's violal alliance of hypogynous Exogens. Herbs or undershrubs with branching stems, and opposite exstipulate leaves with a sheathing base. Flowers sessile, imbedded in the leaves; sepals four to five, united in a furrowed tube, persistent; petals alternate with sepals, often with scaly appendages; stamens four to five or twice these numbers, the anthers roundish, versatile, opening lengthwise. Ovary superior, with a slender cleft style, and numerous anatropal ovules attached to parietal placentas. Fruit a one-celled capsule, enclosed by the calyx; seeds very

small. Chiefly natives of North Africa and the south of Europe; a few have been found in South Africa, South America, the temperate parts of Asia, and Australia. They have scarcely any properties of importance. The leaves of *Beatsonia portulacifolia* are used in St. Helena as a substitute for tea. There are six genera, including *Frankenia*, *Beatsonia*, and *Hypericopsis*, and upwards of thirty species. [J. H. B.]

**FRANKENIA.** A genus of small heath-like herbs or sub-shrubs giving name to the order *Frankeniaceae*, distinguished by having the petals furnished with claws which are equal in length to the tube of the calyx, six stamens, a three-cleft stigma, and a three-celled many-seeded capsule. *Frankenia* is represented in Great Britain by *F. laevis*, a procumbent plant, with numerous narrow oblong leaves which grow in tufts, and flowers rising from the forks of the stems or from the axils of the upper leaves. It grows in muddy marshes by the seaside in many parts of Europe and the Canary Islands; in England chiefly on the eastern coast. Other species come from the shores of the Mediterranean, the Cape of Good Hope, North America, and New Holland. French, *Franquenne*. [O. A. J.]

**FRANKINCENSE.** The odoriferous resin called Olibanum obtained from *Boswellia*. —, EUROPEAN. A resinous exudation of the spruce fir. The name is also applied to *Pinus Teda*.

**FRANKLANDIA.** A proteaceous genus containing only one species, *F. lucifolia*, a small upright shrub, very remarkable in its appearance, having scattered filiform dichotomous leaves, covered with orange-coloured glands and warts. The flowers have a salver-shaped calyx with a straight slender cylindrical tube and four-cleft deciduous limb; four stamens included within the tube of the calyx; and a filiform ovary, with spindle-shaped style, and inversely conical stigma. The fruit is a small nut with a single seed. It is a native of South-west Australia. [R. H.]

**FRASERA.** A North American genus of the gentian family, consisting of biennial herbs with axillary stalked flowers, having a wheel-shaped four-cleft corolla, whose segments have in the middle a glandular depression, protected by a fringed scale. *F. carolinensis*, or *F. Walteri* as it is also called, is a curious little plant found in the morasses of North America. It furnishes a fine gentian-like bitter, and when fresh is said to be emetic and cathartic. The roots have been imported under the name of American Calumba. [M. T. M.]

**FRAXINEÆ.** The ash tribe, a suborder of *Oleaceæ*. It includes those genera which have a winged fruit or samara, with one or more seeds. Among these are comprised the common ash (*Fraxinus*), and the manna ash (*Ornus*). [J. H. B.]

**FRAXINELLA.** *Dictamnus albus*.

**FRAXINELLE.** (Fr.) *Dictamnus albus*.

**FRAXINUS.** The Ash, a familiar tree belonging to the *Oleaceæ*, well distinguished by its fruit, which is dry and indeliquescent, two-celled, two-seeded, compressed, and ending in a leaf-like expansion (samara). *F. excelsior* is indigenous throughout the greater part of Europe, the north of Africa, and some parts of Asia. Not remarkable for robustness, grandeur, or longevity, it rests its claim to distinction among European trees on qualities scarcely less striking. In height, gracefulness of form, and elegance of foliage, it has no superiors, scarcely any competitor. 'Its branches at first keep close to the trunk, and form acute angles with it; but as they begin to lengthen, they generally take an easy sweep, and the looseness of the leaves corresponding with the lightness of the spray, the whole forms an elegant depending foliage.' (Gulpin.) The 'sweep' described by Gilpin is especially remarkable in old trees, the lower pendent branches of which are curved upwards at the extremities in a way which quite typifies the tree. In early spring the spray assumes a characteristic appearance, occasioned by the numerous clusters of flowers which appear at the extremities of the branches, at least a month before the leaves. These flowers are minute and remarkably simple in their structure, being destitute both of calyx and corolla; but, being exceedingly numerous, and of a dark purple colour, they are very conspicuous. They grow in dense clusters on the extremities of those branches which were produced in the former year, and eventually become diffuse, and are finally succeeded by bunches of pendent seeds not inappropriately called keys. The foliage of the ash is very late in making its appearance, and it takes its departure among the first, though the precise time at which it sheds its leaves varies much in different individuals. The leaves are composed of about five pairs of acute notched leaflets with a terminal odd one, which last is occasionally abortive. A variety named *heterophylla* has most of the leaves simple. Another variety is well known as the Weeping Ash, all the existing specimens of which were originally derived from a tree discovered about the middle of the last century growing near Wimpole in Cambridgeshire.

As a timber tree the Ash is exceedingly valuable, on account of its quick growth, and the toughness and elasticity of the wood, in which latter quality it surpasses every European tree. In its younger stages (when it is called Ground-Ash), it is used for walking-sticks, hoops, and hop-poles. The matured timber is converted into ploughs, axle-trees, harrows, oars, carts, ladders, handles for tools and a variety of other implements; and as fuel it is unrivalled. Several American species of ash resemble the European ash in general appearance and qualities. The Ash is the badge of the clan Menzies. French, *Frêne*; German, *Esche*. [O. A. J.]

The Common Ash has perhaps a greater number of superstitions connected with it

than almost any other tree, for it would seem that in England it unites the honours usually attributed to the rowan tree, or mountain ash of Scotland, with those peculiar to itself. Or perhaps the supposed powers of keeping witches at a respectful distance of the mountain ash—

‘Rowan tree and Red Thread  
Keep the witches at their speed—

have been attributed to it from the similarity of the leaves of the one to those of the other, thus giving rise to the name of ash for very dissimilar trees.

One of the most remarkable, and perhaps the most ancient, usages to which the Ash was appropriated, was that of passing children who were ruptured through a cleft in the bole of a young tree. Evelyn says: ‘I have heard it affirmed with great confidence, and upon experience, that the rupture to which many children are obnoxious is healed by passing the infant through a wide cleft made in the bole or stem of a growing ash tree; it is then carried a second time round the ash, and caused to repass the same aperture as before. The rupture of the child being bound up, it is supposed to heal as the cleft of the tree closes and coalesces.’ In this case, where both parents were living, the father presented the child, and the mother received it. In the Museum of Natural History in Worcester is a portion of a young ash which was probably submitted to this operation not many years since, and which did not heal as it grew, but retained an oval aperture in the stem. This superstition lingered until very recently, the late Rev. W. T. Broe describes a case as having occurred in Warwickshire.

A superstition prevailed among the old leeches that a shrewmouse, on creeping over the limbs of man or the lower animals, was the cause of cramp and paralysis. To cure this, a hole was made with an auger in the bole of an ash tree, and a poor live shrew was fastened in with the plug of wood that had been abstracted. It is even now a not quite exploded belief that a shrewmouse running over the foot, will cause lameness, the antidote for which was the application of a twig of ‘shrew ash.’ Thus Gilbert White says: ‘We have several persons now living in the village, who, in their childhood, were supposed to be healed by this superstitious ceremony, derived down, perhaps, from our Saxon ancestors, who practised it before their conversion to Christianity.’ The same author describes the preparation of the ‘shrew ash’ as follows:—‘At the south corner of the plestor, or area, near the church, there stood, about twenty years ago, a very old, grotesque, hollow pollard-ash, which for ages had been looked upon with no small veneration as a shrew ash. Now a shrew ash is an ash whose twigs or branches, when gently applied to the limbs of cattle, will immediately relieve the pains which a beast suffers from the running of a shrewmouse over the part affected; for it is supposed that a shrewmouse is of

so baneful and deleterious a nature, that whenever it creeps over a beast, be it horse, cow, or sheep, the suffering animal is afflicted with cruel anguish, and threatened with the loss of the use of the limb. Against this accident, to which they were continually liable, our provident forefathers always kept a shrew ash at hand, which, when once medicated, would maintain its virtue for ever. The manner of preparing the shrew ash was by means of the shrewmouse as already described, in which doubtless some strange invocations were used; but as we do not know them in these degenerate days, we may suppose the charm is lost. Not so, however, that attributed to the even-leaf from the Ash, that is, where the leaf terminates with two opposite pinnae instead of the usual single terminal leaflet. In Wiltshire and Gloucestershire it is not at all uncommon for the lucky finder of the often much coveted even-leaf to invoke it as follows:—

‘Even-ash, I do thee pluck,  
Hoping thus to meet good luck;  
If no luck I get from thee,  
Better far be on the tree.’

This simple charm keeps away witches; and we can only say that in our younger days we have travelled with an even-leaved ash on many an eerie night, and we never saw a witch.

Evelyn says that ‘the chymists exceedingly recommend the seed of ash to be an admirable remedy for stone. But whether by power of magic or nature, I determine not’—doubtless from the power of its roots to rive rocks, and the facility with which this tree will grow in stony places. Be this as it may, it is, though a very old remedy, now discarded; and, indeed, of the many virtues the Ash was once supposed to possess (and we have not named them all), it now boasts none but the utilitarian one of being a most useful timber tree. However, in this relation we must not forget to mention that the root of the ash yields a most curious veined or cannelled wood in which superstition, ere now, has traced extraordinary figures. Thus Evelyn quotes one Jacobus Gaffarelus for the assertion, in his book of *Unheard-of Curiosities*, that ‘of a tree found in Holland, which being cleft, had, in several silvers, the figures of a chalice, a priest’s ash, his stole, and several other pontifical vestments.’ [J. B.]

**FREE.** Not adhering to anything else; not admate to any other body.

**FREMONTIA.** A remarkable and beautiful Californian bush, belonging to the *Sterculiaceae*. Along with the hand-plant of Mexico (*Chelostemon*), it differs from the others in that group in the flowers having no petals; and from the latter it is readily recognised by the bell-shaped calyx, which remains attached, and does not fall away when the flower withers.

*F. californica* was first discovered by Col. Fremont (whose name it bears), in one of his Californian expeditions in the northern

part of the Sierra Nevada. It forms a deciduous bush four to ten feet high, having much the aspect of an ordinary fig-tree. The rounded five to seven-lobed leaves, however, are smaller than those of the fig, and clothed with rusty hairs underneath.

*Fremontia californica.*

The handsome yellow flowers are produced singly on the ends of short spur-like branches, and consist of a broadly bell-shaped calyx of five spreading divisions, clothed sparsely with cinnamon-coloured down outside; five stamens having their stalks united below into a cup; and an ovoid ovary surrounded by the staminal cup, and terminating in a simple style. The fruits are oval capsules, which, when ripe, split into five woody portions, each of which contains a few black seeds. [A. A. B.]

**FRENCH BERRIES.** The fruits of *Rhamnus infectiorius*, *saxatilis*, *avrygdalinus*, &c.

**FRENELA.** A genus of *Coniferae* of the tribe *Cupressineae*. The flowers are incomplete, the staminate and pistillate ones on the same plant: the former in cylindrical catkins, with numerous stamens, imbricated in six rows; the latter in globular or conical cones of six scales. The seeds are numerous, winged on both sides. It is a resinous tree or shrub of New Holland, with cylindrical or three-angled branches, and ternate, scale-like, persistent, and decurrent leaves. They are two years in ripening their seeds. The name was given by Mirbel after M. Frenel. There are twenty known species. [J. H. B.]

**FRÊNE.** (Fr.) *Fraxinus excelsior*. — **À FLEURS.** *Ornus europæa*. — **À LA MANNE.** *Fraxinus rotundifolia*.

**FRESENIA.** A South African genus of *Compositae* characterised by its yellow flower-heads containing about fifteen florets, all of which are tubular and perfect; and by its achenes crowned with a double pappus, the exterior short and

chaffy, the interior of rough hairs. *F. leptophylla* and *scaposa*, the only species, are dwarf undershrubs, the former with opposite linear smooth, the latter with alternate downy leaves, and both with small terminal flower-heads. [A. A. B.]

**FRESHWATER SOLDIER.** *Stratiotes aloides*.

**FREYCINETIA.** A genus of *Pandaneæ* consisting of climbing or scrambling trees, natives of the Indian Archipelago, Norfolk Island, New Zealand, &c. They have the habit of *Pandanus*, from which they are distinguished by having their male flowers upon an unbranched spadix, by their female flowers having abortive stamens, and by the ovaries having numerous ovules placed on three parietal placenta. The fruit consists of numerous fleshy drupe-like carpels, completely or partially fused together, so that there are many or only one cell containing the numerous seeds. Examples of this genus are shown in Plate 10, fig. c, and Plate 14, fig. c. [M. T. M.]

**FREYERA.** A genus of umbellifers, having the fruit flattened laterally, each half with five sharp wing-like ridges; and comprehending a single herbaceous plant, a native of Illyria, the stem of which is slightly branched, with compound leaves twice divided, the divisions one or three-lobed; flowers white; fruit black. [G. D.]

**FREZIERA.** A South American genus of *Ternstroemiaceæ*, chiefly found in the temperate regions of the Andes. They are evergreen bushes or trees of considerable magnitude, often with the aspect of laurels, but their leaves are usually covered beneath with close-pressed silky down. The little white flowers are usually two or three together, sometimes solitary in the axils of the leaves; they have a five-leaved calyx, five rounded petals, numerous stamens, and a thence to five-celled ovary, which becomes a small dry berry with numerous seeds. *Cleyera*, to which this genus is most nearly allied, has few seeds in each cell. The wood of *F. chrysophylla* is preferred to many others in the Peruvian Andes for making charcoal; its lance-shaped leaves are clothed beneath with golden down. *F. theodes*, a common West Indian species, has smooth leaves like those of the tea, said to be astringent and to have a similar taste. [A. A. B.]

**FILAR'S-COWL.** *Arisarum vulgare*.

**FRIESIA.** The name formerly given to the Tasmanian species of *Arctostelia*.

**FRIJOLES.** A Spanish name for various kinds of pulse.

**FRINGED.** The same as *Fimbriate*.

**FRINGE-MYRTLES.** A name given by Lindley to the *Chamelauciacæ*.

**FRINGE-TREE.** *Chionanthus*.

**FRITILLARIA.** A genus of *Illiceæ* plants of ornamental character, found in

the south of Europe and in Asia. They are perennials, furnished with bulbs, and have erect annual stems with alternate or somewhat whorled often glaucous leaves, nodding bell-shaped flowers, sometimes solitary and terminating the stem, sometimes disposed in the form of a raceme in the axils of the upper leaves, or sometimes collected into a whorl beneath a terminal leafy tuft, this last being the arrangement in the Crown Imperial, *F. imperialis*, one of the most stately of the species. The perianth is six-parted, and each of its segments has a honey-pore near its base; within this are six stamens, and a three-lobed ovary crowned by a three-parted style. In several of the species, especially in the native one, *F. Meleagris*, the colours of the flower are chequered, whence it is said the name is derived, from *frutillus*, assumed to mean a chess-board. [T.M.]

**FRITZSCHIA.** A genus of *Melastomaceæ*, composed of a few dwarf perennial Brazilian herbs, having much the aspect of the common thyme. Their minute leaves are smooth and marked with glandular dots, which is unusual in this family, and the slender twigs are terminated by solitary small purple flowers, which have a tubular calyx, four elliptical petals, eight straight stamens, with ovoid anthers united to their filaments by a short connective which has on its inner face two tubercles or short spurs. The tetramerous structure distinguishes them from some, and the nature of the stamens from others, of their allies. [A. A. B.]

**FRÖBELIA.** *Acrotiche*.

**FRÖLICHIA.** A genus of *Amaranthaceæ* nearly allied to *Gomphrena*, from which it differs in having a tubular perianth five cleft at the apex, and stamens with the filaments united into a long tube. They are natives of tropical America, one species reaching as far north as Illinois; and consist of hairy or woolly herbs, with opposite sessile leaves and spiked flowers, each with three scarious bracts. [J. T. S.]

**FROG-BIT.** *Hydrocharis morsus ranae*. — AMERICAN. *Lunobium*.

**FROG-CHEESE.** A name applied to the larger puff-balls when young.

**FROLE.** (Fr.) *Arbutus Unedo*.

**FROMAGEON.** (Fr.) *Malva rotundifolia*.

**FROMAGER.** (Fr.) *Bombax*. — ÉPI-NEUX. *Bombax Ceiba*.

**FROMENTAL.** (Fr.) *Avena clatior*.

**FROMENT.** (Fr.) *Triticum*. — CULTIVÉ. *Triticum vulgare*. — DES HAIES. *Triticum continuum*. — LOCULAR. *Triticum monococcum*.

**FROND, FRONS.** A combination of leaf and stem, as in many alga and liverworts; also improperly applied to a leaf which bears reproductive bodies, as that of dorsiferous ferns. Linnaeus applied it

to palm leaves, and so destroyed its meaning.

**FRONDOSE.** Covered with leaves; bearing a great number of leaves.

**FRONDIPAROUS.** A monstrosity, consisting in the production of leaves instead of fruit.

**FROPTERA.** A small tree from the Mauritius with alternate evergreen entire leaves and small flowers in axillary clusters or short racemes, forming a very distinct genus, whose immediate affinities have not been ascertained. The dotted leaves and most points of structure are those of *Myrtaceæ*, but the ovary is entirely superior, and the stamens definite.

**FROSTED.** A term applied to surfaces in which a dewy appearance is opaque, as if the drops were congealed.

**FROST-WEED.** *Helianthemum canadense*.

**FRUCTIFICATION.** The parts of the flower; or more properly the fruit and its parts.

**FRUCTIPAROUS.** A monstrosity, consisting in the production of several fruits, instead of the one which is metamorphosed.

**FRUIT.** That part of a plant which consists of the ripened carpels, and the parts adhering to them. —, **SPURIOUS.** Any kind of inflorescence which grows up with the fruit, and forms one body with it, as a pine cone.

**FRULLANIA.** A large genus of *Jungermanniaceæ*, distinguished by its numerous archegones and complicated leaves. The species occur in all parts of the world, but are far more common in tropical or sub-tropical countries than in Europe. *F. tamariisci* is almost universally distributed, and is found abundantly in rather mountainous healthy districts, where it is conspicuous for its purple hue. The leaves in this genus are remarkable for the inflated lobes on their under side. [M. J. B.]

**FRUSTULES.** The joints into which the brittleworts separate.

**FRUSTULOSE.** Consisting of small fragments.

**FRUTA DE BURRO**, of Carthage. A poisonous plant supposed to be a species of *Capparis*. —, of Humboldt. The fruit of *Xylopia grandiflora*. — **DE PARAÓ.** The fruit of *Schmidelia edulis*.

**FRUTEX** (ad). **FRUTICOSE, FRUTESCENT.** A shrub; a woody plant which does not form a trunk, but divides into branches nearly down to the ground.

**FRUTICULUS.** A small shrub.

**FUCACEÆ.** A natural order of dark-spored *Algæ*, consisting of olive-coloured inarticulate seaweeds whose spores are contained in spherical cavities in the frond. Most of them are large species of

a tough leathery substance, and assume a dark colour when dried. Many of them have distinct leafy and even two-ranked appendages, while others are destitute of any distinction whatever between stem and receptacle. In *Humantalia* the frond is a small cup-shaped body, the receptacle being repeatedly forked and many feet long. In many cases the receptacles form little pod-like solitary or fasciculate bodies projecting from the stem, while in others they are merely slight swellings. Another cause of variety of aspect arises from the different nature of the air-bladders by which they are sustained in the water. These are sometimes entirely wanting, sometimes simple, and sometimes compound or arranged in necklace-like rows. In all alike, whatever the habit may be, the spores are contained in cavities resembling the cells of *Dothidea*.

*Fucaceae* exist in all parts of the world calculated for the growth of seaweeds, and, though much more abundant as regards species in warm than in temperate regions, have numerous representatives in the latter. All are probably occasionally attached, but they may exist for centuries as floating masses, as in the instance of the Gulf weed, *Durvillea utilis*, which is remarkable for its having the habit of a *Laminaria*, though belonging truly to this order, and distinguished by the large cells like those of a honeycomb contained in its frond, is used in Chili and elsewhere for thickening soup. The greater part of these plants contain a great quantity of carbonate of soda, which was once procured from them in considerable quantities in the form of kelp, and they in common with some other melanosporns are a fertile source of iodine, one of the most important medicines in the Pharmacopœia. The larger species are collected on many parts of the coast for manure. The fine quality of the wheat in the Isle of Thanet is attributed to the large use which is made of it. [M. J. B.]

**FUCHSIA.** A genus of *Onagraceae* characterised by having a funnel-shaped coloured deciduous four-parted calyx, sometimes with a very long tube; four petals set in the mouth of the calyx-tube, and alternating with its segments; eight exerted stamens; and a long style with a capitate stigma. The flowers are succeeded by oblong bluntly four-cornered berries.

The introduction of the *Fuchsia* into England, about the close of the last century, is due to a sailor, whose wife was induced to sell it to Mr. Leo, nurseryman, of Hammer-smith. It was, however, a hundred years before this time that a monk named Father Plumier discovered the first specimen of the family, which he afterwards dedicated to the memory of Leonard Fuchs. This first species was named *Fuchsia triphylla flore coccinea*, and a description of it is to be found in the works of Plumier, published in 1703. With the exception of *F. excorticata* and *F. procumbens*, which are natives of New Zealand, all the species

belong to the central and southern regions of America, in shady moist places, in forests, or on the lofty mountains of Mexico, Peru, and Chili. The number of distinct species at present known is more than fifty, which have been introduced from time to time since the beginning of the present century; but the varieties most prized by florists date only from the year 1837, when *F. fulgens* was introduced. The introduction of this species, and soon afterwards of *F. corymbiflora*, *cordifolia*, and *serratifolia*, gave to horticulturists the opportunity of hybridising these long-flowered species with the globose kinds, and the result has been the annual appearance of varieties which, from a garden point of view, have surpassed their predecessors, to be themselves eclipsed in their turn. [C. A. J.]

**FUCHSIA, AUSTRALIAN OR NATIVE.**  
A colonial name for *Correa*.

**FUCUS.** A name formerly applied indiscriminately to almost all the more solid *Alga*, though now confined to a single genus of *Fucaceae*. Attempts have been made to subdivide even this from slight differences in the spores or in the disposition of the male organs. *Fucus*, as now generally restricted, comprises those social seaweeds which have a flat or compressed forked frond, the air-vessels when present formed by the occasional swelling of the branches, or in their substance, and also have receptacles filled with mucus, traversed by a network of jointed filaments. *Fucus*, in fact, contains such species as *serratus* and *nodosus*, which are as common on our coasts as grass in the fields. The antherids are produced either on the same or on different plants, and their spermatozooids have been proved to have active functions from their effects on the spores, which, without their access, are not capable of reproducing the species, though they commence an imperfect germination.

Many of the species are more or less exposed at low water. *F. canaliculatus*, however, which is referred by some to a distinct genus, *Pelvetia*, is remarkable for its amphibious habit, growing as it does, frequently on large boulders, where it is dried up by the sun into a hard brown mass. This, however, recovers its usual appearance entirely with the first return of the tide, and is so little incommoded by the change, that it even brings fruit to perfection in such situations. As, however, there is a point beyond which endurance is impossible, it is not known on the coasts of the United States, where the hot burning sun would completely destroy vitality before the return of the tide. The peculiar leathery texture of the frond seems to enable it to bear considerable change without inconvenience.

These plants afford a considerable proportion of the seaweed thrown up upon our shores and collected for manure, as it was formerly for making kelp. Cattle also occasionally browse upon them, or they are boiled and given with coarse meal as food

The gelatinous receptacles are sometimes used as applications to scrofulous swellings. Any benefit which results must depend on the small quantity of iodine which they contain.

Most of the species are confined to the Northern seas. *F. vesiculosus*, though so common under a variety of forms both in the North Atlantic and Pacific, does not exist in the Mediterranean except in floating masses carried in through the Straits of Gibraltar. *F. nodosus* occasionally exists in similar floating masses, and then assumes curious forms which have been registered as distinct species distinguished by their mode of branching and other characters. *F. vesiculosus* is the badge of the M'Nellis. [M. J. B.]

**FUGACIOUS, FUGAX.** Falling off, or perishing very rapidly.

**FUGOSIA.** A genus of *Malvaceæ*, consisting of shrubs, natives of tropical America, Africa, and Australia. Their flowers are surrounded by an outer calyx or involucre of six or more leaves, within which is a five-cleft calyx dotted over with black spots, and five oblique petals. The capsule is three to four-celled, opening through the backs of the carpels. [M. T. M.]

**FUIRENA.** A genus of cyperaceous plants belonging to the tribe *Scirpeæ*, having the inflorescence in solitary spikes, in spikes of three, or in crowded heads of spikes, many-flowered; scales imbricated, the outer frequently empty; stamens three; styles three-cleft; achenes triangular, with the bases of the styles adhering. There are about forty species, mostly natives of the warmer parts of the globe, chiefly in the southern hemisphere. [D. M.]

**FULCIENS.** Supporting or propping up anything; said of one organ which is placed beneath another.

**FULCRA** (adj. **FULCRATE**). Additional organs, such as pitchers, stipules, tendrils, spines, prickles, hairs, &c.

**FULORACEOUS.** Of or belonging to the fulcra.

**FULIGINOUS, FULIGINOSE.** Dirty brown, verging upon black.

**FULVOUS.** Dull yellow, with a mixture of grey and brown.

**FULWA.** A solid buttery oil obtained from *Bassia butyrica*.

**FUMARIACEÆ.** (*Fumeworts*.) A natural order of thalamifloral dicotyledons, belonging to Lindley's berberal alliance of hypogynous Exogens. Herbs with brittle stems, watery juice, alternate cut exstipulate leaves, and irregular unsymmetrical flowers. Sepals two, deciduous; petals four, eruciate, irregular, one or two of them often saccate or spurred, and the two inner frequently cohering at the apex so as to include the anthers and stigma; stamens either four and free, or six and diadelphous, each bundle being opposite the outer petals, the central anther two-celled, and

the two outer one-celled. Fruit around and indehiscent achene, or a one-celled and two-valved pod; seeds crested with a minute embryo. Natives chiefly of the temperate regions of the northern hemisphere; a few occur at the Cape of Good Hope. They possess slight bitterness and acidity. *Dielytra spectabilis* has very showy flowers. There are about 160 species, distributed in eighteen genera, of which *Hypercium*, *Fumaria*, *Corydalis*, *Dielytra*, and *Platycapnos* are examples. [J. H. B.]

**FUMARIA.** The Fumitory, a genus of herbaceous plants giving name to the order *Fumariaceæ*, among which they are distinguished by having one of the petals swollen or spurred at the base, and a one-seeded capsule which does not open. The species vary but little in habit, being small slender herbs with weak climbing or straggling stems, decomposed leaves, and clusters or spikes of small tubular irregular flowers of a pinkish hue tipped with purple, or rarely white. Several kinds of Fumitory are common weeds in cornfields and other cultivated ground, varying in luxuriance according to the richness of the soil. *F. officinalis* is said to be a common weed throughout the world, and has been long esteemed for its medicinal virtues, the juice having been recommended as a purifier of the blood, and an infusion of the leaves as a cosmetic. Though now not valued in England, it occurs in lists of French medicinal plants as a depurative. French, *Fumeterre*; German, *Erdrauch*. [C. A. J.]

The Fumitory is essentially an agrarian plant, tracking both garden and field culture over a great part of Asia as well as Europe. It is probably from this cause that the species are so variable, or perhaps we should say, that so many varieties occur; and being sown with different kinds of seeds, such as clover, flax, and other crops, which may be obtained from different parts of the world, we need not wonder if a variable mode of growth should be the consequence of the varying conditions which plants so circumstanced must encounter. The typical species is *F. officinalis*, which was formerly in repute for a variety of diseases. Its generic name, indeed, is said to be derived from the Latin *fumus*, smoke, which, Pliny tells us, was given because the juice of the plant brought on such a flow of tears that the sight became dim as in smoke, and hence its reputed use in affections of the eye. It is now no longer employed medicinally, although a volume might be written of what has been said of its virtues and the many diseases in which it was held as a remedy by a host of physicians from Dioscorides to Cullen. [J. B.]

**FUMETERRE.** (Fr.) *Fumaria*. — **BULBEUSE.** *Corydalis bulbosa*.

**FUMOUS, FUMOSE.** Grey, changing to brown; smoke-coloured.

**FUMEWORTS.** The plants of the order *Fumariaceæ*.

**FUMITORY.** *Fumaria*. —, **BULBOUS** *Corydalis bulbosa*, also *Adoxa Moschatellina*.

**FUNALIS.** Formed of coarse fibres resembling cords.

**FUNARIE, FUNARIA.** A small natural order and genus of acrocarpous mosses with a pear-shaped capsule, and the calyptra much inflated and vesicular below, and subulate above. The peristome is either double, single, or altogether wanting, the vesicular calyptra being the point of greatest importance. *Funaria hygrometrica* grows in all parts of the world, and is extremely common in this country, especially on charred or burnt soil, and is conspicuous from its large calyptra and ceriseous heads. [M. J. B.]

**FUNDAMENTAL.** Constituting the essential part of anything, in a plant, the axis and its appendages.

**FUNDI or FUNDUNGL.** The Hungry Rice, *Paspalum ezile*.

**FUNDUS PLANTÆ.** The collar, or place of junction of root and stem.

**FUNGALIS, FUNGALS.** A name intended to include under one head *Fungi* and *Lichens*, the latter of which are so closely allied that it is often difficult to tell to which division some given species may belong. [M. J. B.]

**FUNGI.** A large class of cryptogams distinguished from *Algae* more by habit than by any general character. They agree with them in their cellular structure, which is void of anything like vascular tissue except in a very few cases, while they differ in their scarcely ever being aquatic, in deriving nutriment from the substance on which they grow, and in the far lower degree of development of the organs of impregnation—the impregnating cells, where they really possess a sexual function, being extremely simple, void of cilia, and therefore possessed of nothing more than molecular motion, the only exception being that of *Leptomitia* and its allies, which seem to be almost intermediate. The myxogastrous *Fungi*, whose spores produce a body resembling certain infusoria, are wholly exceptional, and the indications of animal life which they exhibit point in another direction.

Minute and abstruse as are these differences, it is almost impossible to distinguish certain *Fungi* and *Algae* without them. Take, for instance, a *Peronospora* and a *Chroolepus*. Both exhibit erect branched threads, from the upper part of which cells are produced containing a thick grumous matter. At first sight no one would think they could belong to very different sections of the vegetable kingdom. When, however, we look more closely, we find first, that the one is a true parasite, the other growing indifferently on bark or stone, and deriving its nourishment from the surrounding air; and then when we turn from the habit to intimate structure,

we find that the spores of the *Peronospora* fall off and germinate at once, while the analogous bodies in the *Chroolepus* burst and send out a multitude of minute reproductive bodies moving about for a time by means of long lash-shaped cilia. Zoospores, however, have lately been discovered in *Peronospora*, so that the resemblance is still closer. A second form of fruit which occurs in *Peronospora* shows a greater difference between the two as genera, but not as regards important sectional characters.

Popularly speaking, *Fungi* may be recognised either as the creatures of corruption—springing, that is, from various bodies, whether animal or vegetable, in a more or less advanced stage of decomposition—or as parasites on living bodies, producing an injurious change. The ephemeral tond-stools of the hotbed, the mushrooms of our rich pastures, the sap-balls on decaying trees, the moulds which infest our food and even the tissues of living animals, the mildew bunt and smut of our corn-crops, with many other more or less familiar objects, are so many *Fungi*, all agreeing in the main particulars which we have indicated, and so differing from the green scum of our brooks, and the weeds of the sea, though distinguished from each other by essential differences of structure. In some, no indications of sexual differences have been found, while in others bodies occur, which in all probability have an especial sexual function, though at present we are without actual proof of the fact.

*Fungi* are divided into two great sections, characterised by the mode in which the reproductive bodies are formed. In the one, they are simply the terminal joint or joints of the component threads or cells, altered in form from those which precede them, and at length falling off and reproducing the plant, in which case they are called spores. In the other they are formed from the contents of certain sacs or asci, and are usually definite in number, and multiples of four, where they are not reduced below that number; in this case they are called sporidia. Both spores and sporidia may be multicellular, and in germination give rise to as many threads of spawn as there are cells. In many species of the latter division, a second form of fruit occurs, which is naked as in the first; and in every division two or more kinds of fruit are frequently produced by the same species, a fact which takes from the mathematical precision of the two great divisions, though it does not interfere with their natural affinities.

*Fungi* may be divided into six principal classes, the first four of which bear naked spores, the two latter sporidia:—

1. **HYMENOMYCETES**, in which the fructifying surface is at length exposed, if not so in its first origin. Mushrooms and sap-balls are well-known examples.

2. **GASTEROMYCETES**, in which the fructifying surface is always enclosed at first, and is never completely exposed, except in old age or decay, in consequence of its sinuous intricate character, even

when the peridium bursts. Puff-balls are a familiar example.

3. **CONIOMYCETES**, in which the spawn or vegetative part is reduced to a minimum, and the abundant spores at length form a dusty or more rarely a gelatinous mass. The rust and bunt of corn afford ready instances.

4. **HYPHOMYCETES**, in which the vegetative part consists mostly of threads which are not woven into a solid mass except in a few cases which border on *Hymenomycetes*. The naked-seeded moulds belong to this division.

5. **ASCOMYCETES**, in which the sacs or asci which contain the sporidia are either jammed into an exposed hymenium, or line the interior of the fruit-bearing cysts. Moulds afford an example of the first, and the insect *Sphaeria* of the second.

6. **PHYCOMYCETES**, in which the component threads are more or less free as in *Hyphomycetes*. The common bread mould is an excellent example.

Each of these divisions is again divided. In a few instances the bodies which at first sight seem to be the spores or ultimate fruit, are in reality a sort of prothallus. Sometimes a third evolution takes place before the ultimate spore is formed. The truly parasitic fungi of the third division give us examples.

The uses of *Fungi* are various. To enumerate them here would be merely to go over ground which must be again travelled under individual orders and species. It is sufficient to say that they afford excellent and abundant food, valuable medicines, besides less important assistance in domestic economy. Their office in the organised world is to check exuberant growth, to facilitate decomposition, to regulate the balance of the component elements of the atmosphere, to promote fertility, and to nourish myriads of the smaller members of the animal kingdom. They occur in every part of the world where the cold is not too intense to destroy their spawn, or where there is sufficient moisture, though they abound the most in moist temperate regions where the summer is warm. There are but few certain traces of them in antediluvian strata, and those only in the more recent. Most of them, however, are too soft and fugitive to make it likely that they should have been preserved. [M. J. B.]

**FUNGIFORM, FUNGILLIFORM.** Cylindrical, having a rounded convex overhanging extremity.

**FUNGINOUS.** Of or belonging to a fungus.

**FUNICULUS, FUNICLE.** The cord or thread which sometimes connects the ovule or seed to the placenta.

**FUNILIFORM.** Formed of cord-like fibres.

**FUNKIA.** A genus of *Liliaceæ* found in China and Japan, having fasciculate roots, the leaves usually all radical, stalked, ovate or cordate, acuminate and plaited, the cau-

line ones, when present, sessile. The flowers grow in racemes and are blue or white, with a tubular six-parted perianth, and the style and stamens bent down. The seeds have a black membranous coat, produced into a wing at the apex. A few species are known, and they are mostly introduced to our gardens. [J. T. S.]

**FUNNEL-SHAPED.** A calyx or corolla, or other organ, in which the tube is obconical, gradually enlarging upwards into the limb, so that the whole resembles a funnel, as in the *Convolvulus*.

**FURBIURNE.** An Arab name for *Euphorbia officinarum*.

**FURCATE.** Having long terminal lobes, like the prongs of a fork, as *Ophioglossum pendulum*.

**FURCELLARIA.** A genus of rose-spored *Algae* belonging to the natural order of *Cryptomonaceæ*, with a forked cylindrical fastigiate frond, having the capsules lodged in the pod-like branches. *F. fastigata*, the only known species, which is widely distributed in the Northern Atlantic, is one of the commonest sea-weeds on our coast. It is so like *Polydora rotunda* that it is very difficult to distinguish them except when in fruit; the sponge-like masses in which the capsules of *Polydora* are humered, afford, however, a marked distinction. [M. J. B.]

**FURFURACEOUS.** Scurfy; covered with soft scales, which are easily displaced.

**FURROWED.** Marked by longitudinal channels, as the stem of the parsnip.

**FURZE.** The gorse or whin, *Ulex europæus*.

**FUSAIN.** (Fr.) *Euonymus europæus*.

**FUSANUS.** A genus of sandalworts, having flowers of mixed character, some being perfect, having stamens and pistils; others with stamens or with pistils only. The border of the calyx is deeply divided into four pieces, which spread horizontally like the spokes of a wheel, but ultimately fall off; the stamens are four in number. The species are small trees or shrubs, natives of the Cape of Good Hope, and of the southern parts of New Holland. Dr. Landley states that 'the fruit of the Quandang nut (*F. acuminatus*) is as sweet and useful to the New-Hollanders as almonds are to us.' [G. D.]

**FUSARIUM.** A genus of moulds closely resembling *Fusisporium*, but consisting of *Fungi* which burst forth from beneath the cuticle of the plants on which they grow, in little gelatinous spots. *F. heterosporium* has affected rye in the south of England during hot seasons, and *F. Mori*, a species first described by Léveillé, is the pest of the white mulberry crops cultivated for silkworms, forming on the leaves brown gelatinous specks which exhaust their nutritive qualities. The other species are of

little importance from an economical point of view. [M. J. B.]

**FUSETTE.** The Spanish name for *Rhus Cotinus*.

**FUSISPORIUM.** A genus of moulds with septate spindle-shaped spores springing from free mucedinous threads, and at length forming a gelatinous mass. It is distinguished from *Fusarium* by its not bursting forth from beneath the cuticle as in that genus. Several of the species are destructive to vegetables, such as turnips, beet-root, gourds, &c. *F. Solani* is extremely injurious to potatoes, and in company with *Peronospora infestans* hastens the decomposition which is due to that parasite, or converts the tubers into a hard dry innutritious mass. The flocci are, however, too much developed to make this a typical *Fusisporium*. [M. J. B.]

**FUSCOUS.** Brown, with greyish or blackish tinge.

**FUSIFORM.** Thick, tapering to each end; as the root of the longradish. Sometimes conical roots are called fusiform.

**FUSTET.** (Fr.) *Rhus Cotinus*.

**FUSTIC.** A dye-stuff, consisting of the wood of *Machura tinctoria*. —, YOUNG. The wood of *Rhus Cotinus*.

**GÆRTDIA.** A genus of *Begoniaceæ* having the staminate and pistillate flowers on the same plant, arranged in dichotomous cymes. The staminate flowers have a white four-leaved perianth, and twenty to thirty stamens; and the pistillate ones, which also have a white four-leaved perianth, have a three-winged ovary with three central bifid placentas. They are Brazilian shrubby plants with smooth shining jointed stems and branches, semicordate leaves, and large shining deciduous stipules. The four known species are included by most authors under *Begonia*. [J. H. B.]

**GÆRTNERA.** A genus of opposite-leaved bushes or small trees of the *Logania* family, differing from most of the genera in the fruits being two-celled berries with one or rarely two instead of numerous seeds in each cell. The erect and not lateral attachment of the seeds serves to distinguish them from their nearest allies. The greater number of the thirty known species are found in Mauritius and Madagascar, the remainder in W. Africa and the Malayan peninsula and islands. The smooth entire leaves are lance-shaped, ovate or elliptical, and the flowers are white, green, or rose-coloured: in some species not unlike those of the common privet and arranged in a similar manner, in others disposed in compact terminal heads, and in a goodly number in corymba. The calyx is usually very minute, but in *G. calycina*, a Mauritian species, it is enlarged, bell-shaped, and coloured. The corolla tube has a flat border of five narrow lobes, and bears on its inner face five stamens. The ovary becomes, when ripe, a

white, black, or blue berry about the size of a pea, with two seeds. [A. A. B.]

**GAGEA.** An extensive genus of *Liliaceæ* formerly included in *Ornithogalum*, from which it is easily distinguished by the seeds having a yellowish (not black) seed-coat, and the stamens adhering more distinctly to the segments of the perianth. The species are natives of Europe, temperate Asia, and northern Africa, and resemble each other closely in having linear root-leaves, and a scape with a terminal bracted umbel or corymb of greenish-yellow flowers rather large for the size of the plants. The perianth is persistent, of six patent nearly equal divisions; the stamens six; the style terminated by a three-lobed stigma; the capsule three-celled and three-valved. *G. lutea* is a British species, though rather rare; it is distinguished from allied European species by having no accessory bulb included in the common envelope. [J. T. B.]

**GAGLEE.** *Arum maculatum*.

**GAJAC.** A name applied in French Guiana to the wood of *Dipteryx odorata*.

**GAILLARDIA.** A genus of handsome annual or perennial North American herbs of the composite family, chiefly found in the Southern States, some extending to Oregon, and *G. aristata* reaching across the Rocky Mountains to the Winnipeg Valley. The chief features of the genus are the slender bristles instead of chaffy scales of the receptacle, the long and filiform styles, the neuter ray florets, and the villous achenes crowned with a pappus of six to ten membranaceous one-nerved scales, which are prolonged into an awn. The leaves are sometimes pinnatifid, but more generally entire or obscurely toothed, lance-shaped and rough, the cauline ones sessile. The flower-heads, about two inches across, are single and supported on naked stalks, the strap-shaped ray florets three to five-toothed, sometimes brick-red or purple below, sometimes altogether yellow. The slender hairs of the stems and leaves are seen to be curiously jointed when looked at through a lens. Six species are known, all of them pretty border plants. [A. A. B.]

**GAILLET.** (Fr.) *Gallium*.

**GAIMARDIA.** A genus of *Desmanaceæ*, differing from the rest of the order by having two instead of only one stamen. It contains a small tufted herb from the Maclovian Islands, with erect stems branched at the apex and densely leafy; the branches with scattered leaves; the leaves imbricated, bayonet-shaped, with sheathing bases; the flower-spike solitary terminal, with one-flowered spikelets. [J. T. B.]

**GAINIER COMMUN.** (Fr.) *Cercis Siliquastrum*.

**GAIROUTTE.** (Fr.) *Lathyrus Cicera*.

**GAITER BERRIES.** The fruits of *Cornus sanguinea* and *Euonymus europæus*.

**GALA, GALACTO.** In Greek compounds = milk or white as milk.

**GALACTITES.** A genus of *Compositæ* peculiar to the Mediterranean region and the Canary Islands. The three known species have much the aspect of, and are nearly allied to, *Onitis*, differing chiefly in the outer florets of the flower-head being sterile and larger than the others, as in *Centaurea*. The stems seldom exceed two feet high; the leaves are pinnatifid with spiny-pointed segments, spotted with white above, and covered with cottony down below, the bases of the upper ones decurrent, and forming a wing to the stems. The flower-heads, which contain numerous white or pink florets, are either clustered and sessile on the ends of the branches, or grow simply on long stalks. *G. tomentosa* is remarkable among the thistles for having a milky juice like that so common in the cichory group. [A. A. B.]

**GALACTODENDRON.** A generic name given by some authors to the celebrated Cow-tree or 'Palo de Vaca' of South America, now more generally referred to *Brosimum*: which see. [A. S.]

**GALAM BUTTER.** A reddish-white solid oil obtained from *Basia butyracea*.

**GALANE.** (Fr.) *Chelone*.

**GALANGAL or GALANGALE.** The aromatic *Alpinia Galanga*; also *A. racemosa*, *Allugha*, and *pyramidalis*; in Sweden it is called *Galgant*. Also a common name for *Kæmpferia*.

**GALANT DE JOUR.** (Fr.) *Cestrum diurnum*. — **DE SOIR.** *Cestrum vespertinum*. — **DE NUIT.** *Cestrum nocturnum*.

**GALARDIENNE.** (Fr.) *Gaillardia*.

**GALANTHUS.** A genus of *Amaryllidaceæ* characterized by having a six-leaved bell-shaped perianth, the exterior segments concave and spreading, the interior shorter, erect, and emarginate; six stamens inserted on an epigynous disk, with very short filaments and erect convergent anthers; a straight filiform style with simple acute stigma; and a three-celled ovary with numerous ovules. *G. nivale* is the common Snowdrop, a dwarf bulbous plant found in some parts of England, and having a pair of narrow linear glaucous leaves, and drooping white flowers dotted with green on the inner segments, and generally solitary at the top of the short scape. *G. plicata*, the Crimean Snowdrop, is similar, but larger and handsomer, with the leaves broad linear and plicate. Our English Snowdrop is welcomed as one of the earliest floral harbingers of spring, the 'first pale blossom of the unripened year,' and a double-flowered variety is much cultivated. [T. M.]

**GALATELLA.** A genus of perennial herbs of the composite family, numbering about twenty species, found in the temperate parts of Asia, one species only occurring in the United States. They have much

the appearance of *Aster*, and only differ in the ray florets being neuter; while from *Linosyris* they differ in the ray florets being white or purple, never yellow. The stems are simple below, branching above, and furnished with narrow entire leaves, and numerous flower-heads arranged in terminal corymba. The ray florets are white or blue, those of the disk yellow; and the achenes are hairy or villous and crowned with a pappus consisting of numerous rigid and filiform rough bristles. [A. A. B.]

**GALAX.** A genus of doubtful affinity which has been recently taken by Aas Gray as the type of *Gulacinea*, a sub-order of *Diapensiaceæ*, of which *Shortia* is the only other genus. 'Its somewhat gamopetalous corolla is deeply-parted, and the stamens with the interposed squamules or sterile series of stamens, are connate into a tube, which not a little resembles the corolla of *Diapensia*, the fertile stamens occupying the sinuses of its petaloid divisions, instead of those of the corolla. The style also is short, and there is no persistent columella in the axis of the capsule. Galax has been referred to the *Pyrolaceæ*, but the points of resemblance are few, and the differences many and great in corolla, androecium, style, seeds, etc.' The only species, *G. ophylla*, a smooth perennial stemless herb with a scaly creeping rhizome, roundish evergreen all radical leaves, and a long spiked raceme of small white flowers, is a native of open woods in Virginia and N. Carolina. [J. Br.]

**GALAXIA.** A genus of Cape *Iridaceæ*, forming dwarf plants with bulb-tuberous rhizomes, short stems bearing a terminal cluster of narrow leaves and handsome flowers, consisting of a funnel-shaped perianth, with a slender terete tube, and six-parted equal limb of oblong wedge-shaped spreading segments, the outer of which have a nectariferous cavity at the base. They have three stamens, with the filaments connate into a short tube, and the arrow-shaped anthers affixed by their base; a filiform triquetrous club-shaped style with three fringed convolute stigmas; and a three-celled ovary containing many ovules. There are some five or six species. [T. M.]

**GALBA.** A durable Indian wood produced by *Calophyllum Calaba*.

**GALBANUM.** A Persian umbelliferous plant, the fruit only of which is known, has been described under this name, from the supposition that it was the source of the drug galbanum; it seems, from the imperfect material known, to belong to the genus *Polyophtum*. The fruits of *G. officinale* are elliptical and flattened from back to front; each half-fruit has seven elevated bluntly keeled ridges; the intervening channels are broad, and have no vitæ or reservoirs for oil, but on the commissure or surface by which the two halves of the fruit are in contact, there are two vitæ. [M. T. M.]

The name Galbanum is also applied to a balsamic gum-resin, of which that obtained from Persia is ascertained to be produced by *Ferula galbaniflua*; its properties are similar but inferior to those of asafetida. It is supposed to be also yielded by other umbellifers.

**GALBULUS.** A strobilus, whose scales

are fleshy, and combined into a uniform mass; as the fruit of the juniper.

**GALE, SWEET.** *Myrica Gale*.

**GALEA.** The helmet or arched part of a flower, always placed at the back, that is, next to the axis.

**GALEANDRA.** This was formerly recognised as a distinct genus of orchids, but is now referred to *Eulophia* by Dr. Blume. The Mexican *G. Baueri*, frequently cultivated by orchid growers, is epiphytal, with cylindrical stems bearing several lance-shaped nerved leaves, and beautiful drooping racemes of yellow flowers, the lip having parallel purple lines near the apex, which has wavy margins. *G. Devoniana* is another handsome species, with large chocolate-coloured flowers, having a funnel-shaped white lip marked with pink lines. [A. A. B.]

**GALEARIA.** A genus of handsome laurel-leaved bushes found in the Malay Peninsula and Archipelago, referred by recent authors to the *Euphorbiaceae*. It produces solitary and terminal, often drooping flower-spikes, which are sometimes more than a foot long. The leaves are accompanied by minute stipules, and the minute green flowers are dioecious, the males with a five-parted calyx, five concave petals, and ten free stamens; the females with similar calyx and corolla, and an ovary crowned with three or five minute stigmas. The fruits are rounded, fleshy, about the size of a pea when only one cell is perfected, larger and two or three-lobed when two or three are perfected; each cell containing one seed. [The name *Dennettia*, which, including *Crematoschys*, represents a genus of about a dozen species, is now adopted, for these plants.] [A. A. B.]

**GALEGA.** A genus of smooth erect perennial herbs of the leguminous family, having pinnate leaves, arrow-headed stipules, and long axillary racemes of pretty lilac or white pea-flowers. The few known species are found in the Mediterranean region, and extend eastward to Persia. They are nearly related to *Glycyrrhiza*, but the pods are narrow and smooth, and contain numerous seeds, while those of the liquorice are broad, usually rough externally, and one to four-seeded. The roots have a sweetish taste. The stems are furnished with unequally pinnate leaves made up of eight to ten pairs of ovate lance-shaped or linear leaflets. *G. officinalis*, the Goat's Rue, was at one time in repute as a cordial in fevers and convulsions, but it has long fallen into disuse. The generic name, derived from the Greek signifying milk, refers to its supposed property of increasing the milk of animals which feed upon the plants. [A. A. B.]

**GALENIA.** A genus of *Tetragoniaceae* consisting of herbs or shrubs from the Cape of Good Hope, usually much branched, hairy or papillose, with alternate or opposite

entire fleshy leaves and sessile flowers, generally cymose or paniculate. Calyx deeply four or five-cleft, coloured within; corolla absent; stamens eight or ten; ovary two to five-celled; capsule woody or corky, varying in shape according to the number of cells in the ovary. [J. T. S.]

**GALEOBDOLO.** The name of a section of *Lamium* distinguished by having the corolla tube obliquely annulate within, contracted below, and dilated and subventricose above the annulus, where it is also somewhat recurved and lengthened out; and by the helix being elongated and narrowed at the base. The principal species, *Lamium Galeobdolon*, our native Archangel, is sometimes separated under the name of *G. hibernicum*. [T. M.]

**GALEOGLOSSA.** The name of certain Ferns, otherwise referred to *Niphobolus*.

**GALEOPSIS.** A genus of labiates, called Hemp-nettles, distinguished by their equally five-toothed calyx, by the two lower stamens being longer than the other pair, by the two-lipped corolla, of which the upper lip is arched, the lower three-lobed, and by the diverging anther-cells, which open longitudinally. The commonest species is *G. Tetrahit*, an annual weed frequently met with in cultivated ground. It grows to the height of a foot or more, and is well marked by its hispid stem, which is singularly swollen beneath the joints, by the very long rigid calyx teeth, and by the purple, sometimes white, flowers. *G. Ladanum* has the stems less hairy than the last, and the stem is not swollen beneath the joints; it grows principally on a limestone or chalk soil. *G. versicolor* approaches in habit to *G. Tetrahit*, from which it may be distinguished by its more showy yellow flowers having a blotch of purple on the lower lip; this is found in several parts of England, but is most abundant in Scotland, especially in cultivated fields among the Highlands. *G. ochroleuca*, with large pale yellow flowers without spots, grows in sandy cornfields, but is rare. French, *Galeope*; German, *Tauhe Nessel*. [O. A. J.]

**GALEOTTIA.** This name has been given to an obscure Mexican orchid supposed to be closely allied to *Datemanntia*, but to differ in having a large ovate gland and short caudicle, *Datemanntia* having no caudicle. It has besides been applied to a genus of *Acanthaceae*, which has also been called *Glockeria*, and is related to *Stenostaphanus*, from which it differs in its bilabiate corolla. This latter is a Mexican shrub, with mutant crimson flowers in terminal panicles. [T. M.]

**GALEWORTS.** Lindley's name for the *Myricaceae*.

**GALIACEÆ.** (*Stellates, Maddeworts.*) A natural order of calycifloral dicotyledons belonging to Lindley's clinchonal alliance of epigynous Exogens. The order has been sometimes called *Stellatae* from the star-like arrangement of the leaves; and by many it is reckoned as a suborder of *Bu-*

*biacea*, which is thus made to include both *Cinchonaceae* and *Galiaceae*. Herbs with whorled exstipulate leaves, and angular stems. Calyx superior, the limb obsolete, four to five or six-lobed; corolla gamopetalous, rotate or tubular, regular, divided like the calyx; stamens equal in number to the corolline lobes and alternate with them. Ovary two-celled, with solitary erect ovules; styles two; stigma undivided. Fruit two-celled, with two seeds; embryo in the axis of horny albumen. Natives of the northern parts of the northern hemisphere, and of high mountains in South America and Australia. The order contains some plants used for dyeing and some having tonic qualities. The horny albumen of goose-grass or cleavers (*Galium aparine*) has been used as a substitute for coffee. The root of madder (*Rubia tinctorum*) is employed as a dye, and supplies the Turkey-red; that of *Rubia cordifolia* furnishes the dye called murex in India. The leaves of woodruff (*Asperula odorata*) are fragrant when dried. There are ten known genera and about 380 species. Examples: *Galium*, *Rubia*, *Asperula*. [J. H. B.]

**GALIMETA WOOD.** The timber of *Bumelia salicifolia*.

**GALINGALE.** *Cyperus*, especially *C. longus*.

**GALININGUE.** (Fr.) A kind of olive.

**GALINSOGA.** A genus of annual South American weeds of the composite family, furnished with opposite ovate three-nerved nettle-like leaves, and small axillary or terminal stalked flower-heads having an involucre of three to five ovate scales, enclosing four or five white or purple ray florets with pistil only, and numerous yellow tubular perfect disk florets; the angled achenes are crowned with a pappus of lacerated chaffy scales, and seated on a conical chaffy receptacle. *G. parviflora*, a species with smooth leaves, white ray florets, and a habit like that of the annual mercury, is naturalised in many countries, and has become a pest in the market gardens about Kew and Richmond. [A. A. B.]

**GALIOTE.** (Fr.) *Geum urbanum*.

**GALIPEA.** A genus of rutaceous shrubs or small trees, natives of tropical America, the flowers of which have a salver-shaped corolla with spreading acute lobes; four to seven stamens, somewhat adherent to the petals, sometimes all fertile, but usually only two of them antheriferous; a cup-shaped disk; five styles, becoming ultimately fused into one, with a four to five-grooved stigma; and five or fewer carpels. The bark of one or more of the species, such as *G. officinalis* and *G. Cusparia*, is used in medicine as an aromatic or stimulant tonic. Dr. Hancock, who had large experience of its use in tropical South America, even preferred it to cinchona in the treatment of fever. In this country it is but little used, being deemed inferior to other remedies, and possibly from the fact that a false Angostura bark was at one

time, through inadvertence or cupidity, substituted for the genuine bark. This false bark occasioned several dangerous accidents, which led some of the continental governments to prohibit the use of Angostura or Cusparia bark. The spurious bark proved to have been really derived from the deadly nux-vomica tree. This nux-vomica bark, it appears, was also sold in Calcutta for the harmless bark of *Soymdia febrifuga*; and a preparation of the former, to be used instead of quinine by the Indian army, was made under the impression that it was a valuable and harmless remedy. Dr. O'Shaughnessy fortunately discovered the error in time to prevent the dreadful consequences which might have ensued from the employment of this preparation. The reader is referred to *Pereira's Materia Medica* (ii. part ii. p. 1915) for full details as to the means, chemical and otherwise, of distinguishing the true from the false Angostura barks, the most readily recognisable features of the true bark being, that it occurs in pieces which are not so much twisted or bent as the nux-vomica bark, that it has a disagreeable odour which is not noticed in the false bark, and from being lighter is more readily broken or cut. It is stated that the natives employ the true Angostura bark to stupefy fishes, in the same way that cinchona bark is said to be used by the Peruvians. [M. T. M.]

**GALIUM.** The typical genus of *Galiaceae*, consisting of numerous herbaceous plants, distinguished by having a minute almost obsolete calyx, a four-lobed wheel-shaped almost tubeless corolla, and a fructification consisting of two seed-vessels, each containing a single dry seed. Upwards of 160 species are described, of which fourteen are British. They all agree in having square stems and whorled leaves; and the roots of most afford a purple dye. Some are perennials, others annual. The predominating colour of the flowers is white; and the number of leaves in a whorl varies from four to ten. Of the British species, *G. verum*, Bedstraw, and *G. cruciatum*, Cross-wort, are perennial, and bear yellow flowers. *G. aparine*, Goose-grass, derives its English name from the avidity with which the young stems and leaves are eaten by geese; it is called Cleavers on account of the tenacity with which the fruit adheres to any rough and soft substance. It is a long straggling annual plant, abundant in hedges and among bushes, through which it climbs, supporting itself by the hooked prickles with which it is copiously invested. The globular seeds covered with hooked prickles, found on the dress of persons who walk through bushy places in autumn, are derived from this plant. *G. saxatile* is the pretty little species, only a few inches high, which is so frequently seen in heathy places, associated with wild thyme, bird's-foot trefoil, and tormentil; its flowers are of a brilliant white, and are succeeded by reddish fruit which is conspicuous by its abundance. French, *Gallet*; German, *Labkraut*. [C. A. J.]

**GALL OF THE EARTH.** *Mulgedium floridanum*, or, according to Dr. Asa Gray, *Nabulus Fraseri*.

**GALLIESIA.** A genus of *Phytolaccaceæ*, a large Brazilian tree, with alternate stalked ovate or oval entire pellucid-dotted, smooth leaves, small tubercular stipules, and a many-flowered terminal panicle of sessile flowers, each with three bracteoles, and having a four-parted calyx and numerous stamens in two rows. The fruit is a samaroid achene, with a large scimeter-shaped wing at the apex. [J. T. S.]

**GALLINHA CHOCA.** *Erythroxylon suberosum*.

**GALLS.** Excrescences of various kinds and forms produced in plants by the presence of the larvæ of different insects. The forms which they assume are multitudinous, and the changes produced in the tissues various. They occur on all parts of the plant, and sometimes in great quantities, but they appear in general to do little harm if they do not attack the parts of fructification. It is probable that the change of growth depends in the first place upon some acrid fluid discharged together with the egg. The process of caprification, in which figs are stimulated to generate juicy instead of dry tissues, is strictly analogous, though there is no external alteration of form. The rootlike galls in grasses are produced by larvæ between the sheath and the stem, and not penetrating the substance. [M. J. B.]

**GALPHIMIA.** An anagram of *Malpighia*, applied to a genus of Mexican malpighiaceans shrubs, some of which are cultivated as evergreens in our stoves. They have a five-parted calyx whose segments are mostly destitute of glands; five stalked petals generally ribbed on their outer surface; ten stamens slightly adherent at the base; and a three-lobed, three-celled ovary with a solitary pendulous ovule in each compartment. The fruit consists of three two-valved carpels. [M. T. M.]

**GALUNCHA.** An Indian febrifuge prepared from the stems of *Tinospora verrucosa* and *cordifolia*.

**GAMASS.** The Squamash or Biscuit-root, *Cassassia esculenta*.

**GAMBIR.** A powerful astringent obtained from *Uncaria gambir*, and employed as a substitute for catechu.

**GAMBOGE, AMERICAN.** The juice of *Flemia guianensis*. —, **CEYLON.** A gum-resin obtained from *Garadnia Morella*, also called *Hebradendron gambogioides*. —, **MYSOKE.** The gum-resin of *Garadnia pictoris*, otherwise *Hebradendron pictorium*. —, **SIAM.** A gum-resin produced by *Garadnia Morella* var. *pedunculata*, of which an account and figure are given by Mr. D. Hanbury, in *Lia. Franc.* xxiv. 487, t. 50.

**GAMO.** In Greek compounds = united by the edges; thus *gamophyllus* signifies leaves united by their edges, while *gamo-*

*sepalous* means monosepalous, and *gamopetalous*, monopetalous.

**GAMOLEPIS.** A small genus of South African *Compositæ*, having smooth entire three-lobed or pinnatifid leaves, and terminal solitary or corymbose, long-stalked flower-heads containing numerous florets. They are nearly related to *Leucanthemum*, but differ in the scales of the involucre being in one series, and more or less united by their margins so as to form a cup. The ray florets are strap-shaped, and contain only a pistil, the disk florets being tubular and perfect; while the achenes are smooth wingless and destitute of pappus. [A. A. B.]

**GAMOPLEXIS orobanchoides** is the name of a tuberous-rooted North-west Indian orchid which is destitute of leaves, and has the aspect of an *Orobanche*. It is notable for its parasitism, which is rare amongst endogenous plants. Dr. Falconer states that the tuberous rhizome emits no root-fibres by which to fix itself on other plants, but is itself matted over by their slender rootlets, giving rise to the appearance of the plant being the subject of a parasitical growth rather than a parasite itself. The stem is one to two feet high, pale straw colour, terminating in a long raceme of flowers. The lip is combined with the sepals and petals to form a tubular perianth, whence the name of the genus; and the pollen is not waxy or powdery, but granular as in *Gastrodia*, which differs in the lip being free, instead of connate with the tube of the perianth. [A. A. B.]

**GANDASULI.** (Fr.) *Hedychium*. — **À BOUQUETS.** *Hedychium coronarium*.

**GANGLIA.** The mycelium of certain fungals.

**GANGRENE.** A disease ending in putrid decay.

**GANITRE.** (Fr.) *Elaeocarpus*.

**GANNE.** (Fr.) *Motina cœrulea*.

**GANTS DE NOTRE DAME.** (Fr.) *Campanula Trachelium*; also *Aquilegia vulgaris*, and *Digitalis purpurea*.

**GANTELEÈ.** (Fr.) *Campanula Trachelium*; also *Digitalis purpurea*.

**GANTIÈRE.** (Fr.) *Digitalis purpurea*.

**GANYMEDES.** A name proposed for a few species of *Narcissus*, e.g. *N. triandrus*, *puchellus*, *nastans*, &c. They are called Rush Daffodils from the rush-like leaves. The perianth has a slender drooping tube and reflexed limb, the cup or coronet is equal to or shorter than the limb, the sepals stamens are prolonged, and the style is straight and slender. [T. M.]

**GABANCE.** (Fr.) *Eubia tinctorum*.

**GARB.** *Salix babylonica*.

**GARBANZOS.** The Spanish name of the Gram, *Oxycor arletinum*.

**GARCINIA.** A genus of *Olusaceæ*, consisting of several opposite-leaved trees

whose stems yield, in greater or less quantity, a yellow resinous juice which in *G. Moralla* is known as Ceylon Gamboge. The chief features of the genus are: unisexual or rarely perfect flowers, having a calyx of four rounded leaves, and four petals of similar form; in the males numerous stamens which are free or united into one or four parcels; and in the females a few barren stamens surrounding a globose ovary which is from two to ten-celled with one ovule in each cell, and is crowned by a shield-like entire or lobed stigma.

The greater portion of the species are found in India and the Malay Archipelago. All have glossy laurel-like leathery leaves. The flowers are either white tinged with pink, or yellow, and arranged in clusters in the axils of the leaves or in panicles at the ends of the twigs. The species from which the Gamboge or Camboge of commerce is obtained in largest quantity are frequently known under the name CAMBOGIA: which see. *G. pictoria*, which is found in the Coorg district of Malabar, yields a gamboge said by Dr Christison and others to have properties similar to those of the Ceylon and Siam gamboge, being 'excellent as a pigment, efficient as a purgative, and equal to the gamboge in common use.' It does not, however, appear to be imported in any quantity, by far the greater portion brought to this country being sent from Siam to Singapore and shipped from that port. This plant is a tall tree with elliptical leaves, small yellow axillary solitary flowers, and berries about the size of a cherry, with four one-seeded cells.

The Mangostan or Mangosteen (*G. Mangostana*), so well known for its luscious fruit, is found in the Malay islands, where it grows to a tree of middling stature with a conical head, the branches furnished with glossy leathery elliptical-oblong pointed leaves, and the flowers single and nearly sessile at the ends of the twigs, of a dull red colour, and as large as dog-roses. Dr. Abel, writing of the fruits of Batavia, says: 'First in beauty and flavour was the celebrated Mangostan. This, so often eulogised by travellers, certainly deserves much of the praise bestowed upon it. It is of a spherical form, of the size of a small orange, when ripe reddish-brown, and when old of a chestnut-brown colour. Its succulent rind is nearly the fourth of an inch in thickness. It contains a very powerful astringent juice, and in wet weather exudes a yellow gum which is a variety of gamboge. On removing the rind, its esculent substance appears in the form of a juicy pulp having the whiteness and solubility of snow, and of a refreshing, delicate, delicious flavour. We were all anxious to carry away with us some precise expression of its qualities; but after satisfying ourselves that it partook of the compound taste of the pine-apple and peach, we were obliged to confess it had many other equally good but utterly inexpressible qualities.' Any amount of the fruit may be eaten without injury, and it is said to be given to those

afflicted with fever along with the sweet orange. The Chinese use the bark as a basis for a black dye, and it is also used in dysentery. In 1855 it first produced its blossom and fruit in this country in the gardens of the Duke of Northumberland at Syon, from whence it was figured by Sir W. J. Hooker in the *Botanical Magazine* (t. 4847). It has been cultivated in the south-

*Garcinia Mangostana*.

ern and eastern parts of India, but does not there attain the same perfection as it does in the Malay Archipelago. A few small-flowered species, with the stamens in four parcels, and the two-celled ovary crowned with a shield-like stigma, are by some authors kept as a separate genus under the name *Discostigma*. [A. A. B.]

GARDENER'S GARTERS. *Phalaris arundinacea variegata*.

GARDENIA. A genus of *Cinchonaceae*, and a favourite with cultivators on account of the fragrance and beauty of its flowers. It consists of trees or shrubs, frequently spiny, and indigenous in tropical Asia and Africa, as well as at the Cape of Good Hope. The calyx tube is ovate, the limb variously divided; corolla white or yellowish, more or less funnel-shaped, with its limb divided into from five to nine somewhat twisted segments, and its tube considerably longer than the calyx; anthers five to nine, sessile on the throat of the corolla, from which they project to a short distance; ovary partially five-celled, with numerous ovules; fruit berry-like, crowned by the limb of the calyx. *G. guianensis* and *G. lucida*, East Indian species, yield a fragrant resin something like Elemi, which might be turned to some account. The fruit of *G. campenulata* is stated by Roxburgh to be used by the natives as a cathartic, and also to wash out stains in silk. Several kinds of this beautiful genus are in cultivation. The Cape Jasmine, *G. florida* and *G. radicans*, both found with double flowers of exquisite fragrance, and *G. Stanleyana*, with long trumpet-shaped blossoms, are among the most beautiful species. [M. T. M.]

GARDENIOLA. The name of a Brazilian shrub of the *Cinchona* family, having numerous flattened branches, with polygamous flowers: the males in groups of three

or five, sessile on the ends of the branches; and the females in similar groups, but stalked. The corolla is salver-shaped, with a short and slightly inflated tube, hairy throat, and four-lobed limb. The fruit is berry-like, black, and two-celled. [M. T. M.]

GARDE-ROBE. (Fr.) *Artemisia Abrotanum*.

GARDNERIA. A genus of *Loganiaceae* composed of two scandent opposite-leaved bushes found in India and Japan. They differ from most in the family in having little berried two-celled fruits, with one or two instead of many seeds in each cell; and the lateral attachment of these in a shield-like manner, not erect from the base, serves to distinguish the plants from their nearest allies. The narrow or broadly lance-shaped leaves are smooth and entire, and the small yellow blossoms are disposed in loose panicles which arise from the axils of the leaves, and in size and form are not unlike those of the privet. The ripe fruits are scarlet berries, about the size of a large red currant, with two seeds. [A. A. B.]

GARDOQUIA. The name of a genus of labiate, having the teeth of the calyx short, straight, and nearly of the same size; the corolla with a long almost straight tube, its upper lip notched, the lower in three lobes, the middle one of which is broadest; style bifid at the end, the divisions small and equal in length. The name was given in honour of Gardoqui, a Spanish financier who promoted the publication of a Flora of Peru. The species are low shrubs or undershrubs chiefly natives of Peru and Chili, rare in North America, and having showy usually pink flowers. [G. D.]

GARGET. An American name for *Phytolacca decandra*.

GARIDELLA. A genus of *Ranunculaceae* consisting of a few herbs from the Mediterranean region and temperate Asia, resembling *Nigella*, but more slender in habit, the ovary containing two or three, not five or more carpels, and the styles very short. They are erect annuals with dissected leaves, and small solitary whitish flowers at the extremity of long peduncles. *G. nigellastrum*, which is found in the south of France, Spain, and Crete, is the most frequent. [J. T. S.]

GARLAND FLOWER. A common name for *Hedychium*; also applied to *Daphne Onocarpum*, *Pleurandra Onocarpum*, and *Erica persulcata*.

GARLIC, or GARLICK. *Allium sativum*. — HEDGE. *Sisymbrium Alliaria*. — HONEY. *Nectaroscordum*.

GARLIC SHRUB. *Bignonia alliacea*; also *Petiveria alliacea*.

GARLICKWORT. *Sisymbrium Alliaria*.

GARO DE MALACA. (Fr.) *Aquilaria ovata*.

GAROU. (Fr.) *Daphne Mesereum*.

GAROUPE. (Fr.) *Onocarpus tricozum*.

GAROUSSE. (Fr.) *Lathyrus Cicera*.

GARNETBERRY. *Ribes rubrum*.

GARRYACEÆ. (*Garryads*). A natural order of monochlamydeous dicotyledons belonging to Lindley's garryal alliance of diclinous Exogens. Shrubs with opposite exstipulate leaves and catkin-bearing imperfect flowers surrounded by united bracts. The staminate flowers have a four-lobed perianth, alternating with four stamens. The pistillate flowers have an adherent two-toothed perianth. Ovary one-celled; styles two; ovules two, pendulous with long cords. Fruit a two-seeded berry; embryo minute in the base of fleshy albumen. The wood is not arranged in circles, and there is an absence of dotted vessels. They are natives chiefly of the temperate parts of America. The few species known belong to the genus *Garrya*. By Benthams and Hooker, this monogeneric group is included in *Cornaceae*. [J. H. B.]

GARRYA. The only genus of *Garryaceae* (see above), composed of opposite-leaved evergreen bushes, found in California, Mexico, Cuba, and Jamaica. *G. elliptica* is one of the most desirable evergreens we have in our gardens, especially as it produces its pale greenish-yellow blossoms in the spring months when little else is in bloom. It was sent from California by the lamented Douglas in 1818. This bush, with much the aspect of an evergreen oak, may be seen sometimes eight to ten feet high, its branches clad with dark green elliptical leaves. The flowers are male and female on different plants, arranged in elegant drooping necklace-like catkins which proceed from near the apex of the shoots, and are often from four to seven inches long. In the male plant (which alone is in cultivation) they are clothed with silky hairs, and a plant covered with these tassels of pale yellow flowers waving in the wind, has a singularly graceful appearance. Each link of the necklace (if we may so speak) is composed of a cup-shaped bract enclosing three flowers, each having a calyx of four divisions and four stamens. In the female the disposition of the flowers is the same. The fruit is a two-seeded berry somewhat like that of the hawthorn in size and shape. The calyx of some species is destitute of the two teeth which are seen in *G. elliptica*, and the tips of the calyx-leaves in the male flowers remain united to each other; these are separated by some authors, who give to them the name of *Fedycnia*, but such differences are not distinctive. The flowers of some species are in compound instead of simple racemes, but none can be compared to *G. elliptica* for beauty. [A. A. B.]

GARUGA. A name applied to a genus of *Amygdaceae* (*Bursaceae*) consisting of trees whose flowers have a five-cleft bell-shaped calyx; five petals inserted between the notched and glandular lobes of a fleshy disk; and a pulpy fruit with five or fewer bony one-seeded stones. *G. pinnata*, an

Indian species, and *G. madagascariensis* are occasionally met with as stove shrubs, with fine pinnated foliage and panicles of yellow flowers. [M. T. M.]

**GARVANCE.** (Fr.) *Cicer arletinum*.

**GASTERIA.** The name of certain species of *Aloe*, which are regarded by some as being distinct from that genus. They are mostly dwarf stemless plants with the thick succulent spotted or warted tongue-shaped leaves often rigidly two-ranked, and the long arching spikes of green-tipped red flowers freely produced. The curvature and bellying of the flower-tubes has suggested the name; the distinguishing character of the group is indeed furnished by the curved tube of the perianth swollen at the base, by the stamens being adglutinated to the perianth at the base, and by the capsule being subcoastate. They are mostly ornamental plants, and, like the other aloes, natives of the Cape of Good Hope. [T. M.]

**GASTEROMYCETES.** One of the six great divisions of *Fungi*, containing those genera with naked spores in which the fruit-bearing surface is either permanently concealed in a surrounding peridium, or in which, when the peridium bursts, the hymenium is complicated like the crumb of a loaf, so that a small portion only is exposed. In *Montagnites*, however, the hymenium consists of true gills. The genera are divisible into six natural groups as follows:—*Podasmiæ*: mostly clavate; hymenium sinuous, enclosed at first in a volvalike peridium, and exposed partially by its rupture, withering or entirely drying up so as to form a dusty mass. *Hypogæi*: subterraneous; peridium seldom distinct. *Phalloidei*: hymenium at first enclosed in a gelatinous volva, at length diffuent. *Nidulariæ*: peridium mostly cup-shaped, enclosing several sporangia. *Trichogastres*: subglobose, not having a distinct volva; hymenium at first cellular, at length leaving a dusty mass of threads and spores. *Myzogastres*: hymenium and mycelium at first gelatinous. [M. J. B.]

**GASTONIA.** The name of a genus of ivy-worts, distinguished by having the corolla with five or six petals; the stamens ten to twelve, attached to the petals, and apparently in pairs opposite to them; the fruit a dry berry with eighteen cells, each of which contains one seed. The name was given by Commerson in honour of Gaston de Bourbon, son of Henry IV. The only species, *G. palmata*, is a native of Mauritius. [G. D.]

**GASTRANTHUS.** A genus of *Geraneæ* containing two species from South America. They are undershrubs with opposite oblong crenate leaves, and few umbellate flowers. The divisions of the calyx are lanceolate; the corolla oblique and shortly spurred, with the limb cut into five unequal small roundish lobes: the four didynamous stamens included; the disk very small, but swelled on

one side into a large gland half covering the ovary; and the apex of the style cup-shaped, and slightly bilobed. [W. C.]

**GASTRIDIMUM.** A genus of grasses of the tribe *Agrostideæ*, consisting of a single species, *G. lendigerum*, or, as it is sometimes called, *G. australe*, one of our rarer British species, and very common in the Mediterranean region. It is an elegant erect-growing annual plant, six or eight inches high, with the panicle contracted into a loose tapering spike two to three inches long, of a pale green, and shining with a satiny lustre. It has been separated from *Agrostis* on account of the polished enlarged base of the outer glumes. [T. M.]

**GASTROCHILUS.** A genus of *Zingiberaceæ*, whose flowers have a tubular calyx, and a corolla with a long tube, the outer segments of the limb equal, the inner ones unequal, the two lateral wide, united at the base with the filament to form a kind of tube, the middle segment or lip large and distended, whence the name. *G. pulcherrima*, a native of Rangoon, and one or two other Indian species, are occasionally met with in cultivation, and are very ornamental. [M. T. M.]

**GASTRODIA.** This is the genus which gives its name to a small tribe (*Gastrodiæ*) of the orchid family characterised by the granular instead of waxy or powdery pollen-masses. There are two known species, *G. Cunninghamii* from New Zealand, and *G. seaumoides* from Tasmania and Australia, both leafless parasites with the aspect of *Orobanche*, and like that found growing on the roots of other plants. The whole plant is of a uniform pale brown colour, the stems one to three feet high, furnished with a few obtuse bracts, and terminating in a long raceme of flowers, the sepals and petals united so as to form a tubular perianth, but the lip free and not connate with the perianth as in *Gamoplectis*. The root of the New Zealand species is eaten by the natives, who call it Peri; it is about eighteen inches long, as thick as the finger, and full of starch. [A. A. B.]

**GASTROLOBIUM.** An extensive genus of the pea family, peculiar to the south-western portions of Australia. It is known by the two-lipped and five-toothed calyx without bracts; the pea-flower corolla with petals nearly equal in length; and the stalked two-seeded ventricose or inflated pods, seldom larger than a pea. *Pullenaea* differs in having sessile pods, as well as heath-like foliage. Most of the *Gastrolobes* are bushes of two to four feet high, with twiggy stems furnished with opposite often whorled leaves varying much in form, and pretty yellow blossoms, sometimes in twos in the axils of the leaves, but more usually in short racemes arising from near the apex of the twigs. A number of the species of this and of allied genera are known in Western Australia as Poison-plants; and farmers lose annually a large number of cattle through their eating the foliage. Mr. James Drummond, in *Hooker's*

*Journal of Botany* (li. p. 333), says: 'The finest and strongest animals are the first victims: a difficulty of breathing is perceptible for a few minutes, when they stagger, drop down, and it is all over with them. After the death of the animal, the stomach assumes a brown colour, and is tenderer than it ought to be; but it appears to me the poison enters into the circulation and altogether stops the action of the lungs and heart. The raw flesh poisons cats, and the blood, which is darker than usual, dogs; but the roasted or boiled flesh is eaten by the natives and some of the settlers without their appearing to suffer any inconvenience.' The poisonous effects were attributed by Mr. Drummond, at the time he wrote this, to a species of *Lobelia*, but he afterwards found out that they were due to the plants of this and allied genera. Dr. Harvey says the worst of the Poison-plants is *G. bilobum*. This plant has oblong nearly smooth slightly two-lobed leaves, placed four in a whorl round the stem, and terminal umbels of pretty yellow flowers, the keel and wing petals marked with purple. *G. spinosum* has similar properties. Altogether there are about a dozen species in cultivation in greenhouses. The generic name has reference to the bellied form of the pods. [A. A. B.]

**GASTRONEMA.** A small genus of South African *Amaryllidaceae*, closely allied to *Cyrtanthus*, and not unfrequently united therewith. The perianth tube is slender below, curved and widely campanulate above, the limb short and reflexed; of the six stamens, which have decurrent conniving filaments and short anthers, the three upper are longer and incurved, the petaline ones inserted at the top, and the sepaline ones near the tube; the style is declinate. *G. clavatum*, the original species, is a pretty little bulb, with slender deciduous leaves and one or two white flowers striped with red. [T. M.]

**GATEN, GATTEN, GATTER, GAITRE, or GATTERIDGE TREE.** *Cornus sanguinea*; also *Euonymus europæus*, and *Viburnum Opulus*.

**GATILIER.** (Fr.) *Vitex Agnus castus*.

**GATTIE.** An Indian gum obtained from the Babool, *Acacia arabica*.

**GAUB.** An Indian name for the astringent medicinal fruit of *Diospyros Embryopteris*.

**GAUDE or VAUDE.** (Fr.) *Roseda Luteola*.

**GAUDICHAUDIA.** A genus of Mexican climbing shrubs, belonging to the *Malpighiaceae*, and remarkable for producing constantly two kinds of flowers, the most numerous and perfect of which have a five-cleft glandular calyx; five stalked toothed petals; five stamens, two of which are usually sterile; three ovaries united at their inner edge; and a fruit winged at the sides and back. The more imperfect flowers

have a calyx without glands; no petals, or only rudimentary ones; and two ovaries with imperfect styles. The flowers are yellow. [M. T. M.]

**GAUDINIA.** A genus of grasses of the tribe *Aveneae*, now generally regarded as forming a section of *Avena*. [D. M.]

**GAULTHERIA.** A large genus of stiff branching ericaceous shrubs or small trees with evergreen leaves, principally inhabiting the American continent, extending from Magalhaens' Strait in the south as far north as Canada and Vancouver's Island. A few are found in Asia, principally in the Himalayas and the mountainous parts of Java; and five or six occur in Tasmania and New Zealand. The leaves are leathery, smooth and shining, and in many species the young branches are covered with bristly hairs. The flowers are small, ovate, with a contracted mouth, and enclose ten stamens; they are white, scarlet, or rose-coloured, and produced singly or in racemes at the ends or from the sides of the branches. The five-lobed calyx frequently increases in size after the flowering period, and sometimes becomes fleshy. The anthers open by pores at the top, and terminate by two bristles. The fruit is small and nearly globose, and when ripe splits open through the middle of each of the five cells.

*G. procumbens*, a little creeping plant, of the Northern United States and Canada, grows about five or six inches high. The erect stiff branches bear tufts of shining, evergreen oval leaves at their summits; and the drooping white flowers, produced singly from the bases of the leaves, are succeeded by fleshy bright red berries, formed by the enlargement of the calyx which encloses the true fruit. All parts of this plant, which is commonly called Wintergreen in the United States, possess a rather pleasant peculiar aromatic odour and flavour, due to the presence of a volatile oil, which, when separated by distillation, is known as Wintergreen oil. It is of a pale green colour, having the same composition as birch-bark oil, and is employed medicinally as a cordial stimulant. The leaves also possess a considerable degree of astringency, and their tincture is useful in diarrhoea. The berries are known by various names, such as Partridge-berry, Chequer-berry, Deer-berry, Tea-berry, Box-berry, &c., and afford winter food to partridges, deer, and other animals. The plant is likewise called Mountain Tea, its leaves being used as a substitute for tea or for flavouring genuine tea.

The Shallon or Salal of the north-west coast of America, *G. Shallon*, is a small shrubby plant, growing about a foot and a half high, flourishing in shady pine forests where few other plants will live. Its dark purple fleshy berries, which are produced in great abundance, have a very agreeable flavour and make excellent tarts; they are much eaten by the natives, who prepare a kind of bread by mashing them together and drying them in the sun. [A. B.]

**GAULTHERIE DU CANADA.** (Fr.) *Gaultheria procumbens*.

**GAURA.** A genus of onagraceae, in which the tube of the calyx is long and three or four-angled below; the corolla of four, rarely three petals, turned to the upper side; the stamens eight, rarely six, those opposite the petals shortest; the fruit a hard woody nut, with three or four prominent angles, and usually four-celled. The name, from the Greek signifying superb, is not generally applicable to the species. The plants are natives of North America, and have alternate leaves varying in outline, and the flowers in spikes, white or rose-coloured, rarely yellow, turning to reddish when fading. [G. D.]

**GAYA.** Tropical American herbs, belonging to the mallow family, having solitary yellow flowers, whose structure is that of the closely allied *Sida*, from which, however, the present genus is distinguished by the capsule, which consists of several one-seeded carpels, opening along the back by two valves, and thus allowing of the protrusion of an inner strap-shaped valve-like appendage. [M. T. M.]

**GAYAC OFFICINAL.** (Fr.) *Guaiacum officinale*.

**GAYAL.** An Indian name for *Agave vivipara*.

**GAYBINE.** *Pharbitis*.

**GAYLUSSACIA.** A genus of tropical American shrubs, belonging to the *Vacciniaceae*, and named in honour of the celebrated French chemist M. Gay-Lussac. The leaves are terminated by a hard spine; the corolla is tubular, distended at the base; and the stamens are inserted into the calyx, the anthers being without horns. The ovary is inferior, and the fruit succulent, crowned by the limb of the calyx, with ten one-seeded stones. *G. Pseudo-vaccinium* is a greenhouse shrub with pretty red flowers. [M. T. M.]

**GAZANIA.** A genus of low-growing herbs of the composite family, peculiar to Southern Africa. The greater proportion are stemless, with a rosette of pinnatifid leaves having linear segments, generally white with close-pressed silky down beneath. In the caulescent species, the leaves are mostly narrow oblong or lance-shaped, glossy green above, white beneath. The flower-heads are large and handsome, with yellow strap-shaped ray florets, and tubular disk florets usually of a darker colour. The principal characters of the genus are: an involucre of many scales, whose margins are united nearly to the summit, so as to form a sort of cup; neuter ray florets; perfect disk florets; and wingless achenes clothed with silky hairs, which nearly hide the double pappus of thin and delicate hairs. The double pappus serves to distinguish this from *Gorteria*, a South African genus of very similar appearance. One of the most handsome and best known of the pinnatifid-leaved species is *G. Pa-*

*vonia*, which has long been in cultivation as a greenhouse plant, and is a beautiful object when its large dark-centred orange-coloured flower-heads, nearly three inches across, are expanded. The plant is said to be one of the greatest ornaments of the waysides in its native country, opening its blossoms only in sunshine. Upwards of forty species are enumerated. [A. A. B.]

**GAZLES.** *Ribes rubrum*.

**GAZON D'ESPAGNE, or D'OLYMPE.** (Fr.) *Armeria maritima*. — **TUIC.** *Saxifraga hypnoides*.

**GEAN.** The wild Cherry, *Cerasus Avium*.

**GEASTER.** A genus of puffballs distinguished by the outer coat or peridium being perfectly distinct from the inner, which contains the spores, and splitting ultimately into several divisions, so as to have the appearance of a star, whence the name of Earth-star. Sometimes the outer peridium consists of two separable coats, of which the inner becomes at length inverted, so that it is lifted up and supported by the tips of its lobes upon those of the outer coat, which gave rise to the Man Fungus of the older herbalists. The inner peridium is either sessile or stipitate, and sometimes without any trace of an aperture for the dispersion of the spores, while in several species there is a distinct orifice which is variously fringed, folded, &c. In *G. coliformis* there are numerous orifices, and many confluent stema. In a young state the hymenium, as in *Lycopodium*, looks like the crumb of bread, and in that condition it has the same structure as the gills of an agaric, though afterwards it dries up, leaving behind a mass of threads and spores. In general each peridium springs from its own mass of spawn, but in a fine species which occurs in Cuba, Ceylon, and Japan, there is a common expanded mycelium. Some of the species, as *G. hygrometricus*, are extremely sensitive of moisture, and are driven about by the wind as shapeless masses, till the first shower expands them like the fruit of the *Mesembryanthemum*. Others, on the contrary, expand when dry, and contract when moist.

The Earth-stars are amongst our rarer, or at least more local fungi, and are found on leaves in shady places, or on exposed banks and sands. They are more common in the south-eastern and southern parts of England than in other parts of Great Britain. Species occur in all warmer latitudes, but do not ascend very high northwards, or if they occur at all it is only in small quantities. [M. J. B.]

**GEBLERA.** The name given by Fischer and Meyer to a Chinese herb of the spurge-wort family, now referred to *Flüßgeria*: which see. [A. A. B.]

**GEIJERA.** An Australian genus of *Rutaceae*, differing from *Xanthoxylon* chiefly in the simple leaves and hermaphrodite flowers. Three species are enumerated: *G. Muelleri*,

with compact panicles, broad leaves, and imbricate nativation; and *G. salicifolia* and *pariflora*, having loose panicles and valvate nativation, the former having ovate or lanceolate, and the latter linear leaves.

**GEISSOIS.** A genus of *Cunoniaceae*, native of New Caledonia, distinguished by having a calyx of four leathery ovate sepals with shaggy hairs on the inside, no corolla, eight to ten stamens with rich crimson filaments an inch long, and a style bearing two stigmas. The seed-vessel is two-celled and two-valved, containing many compressed winged seeds. It consists of a small tree, bearing closely packed flowers in long racemes on the old wood, and opposite leaves with five slightly serrated leaflets. A plant of this genus has been lately introduced which is possibly distinct from the original species, *G. racemosa*, described by Labillardière. [R. H.]

**GEISSOLOMA.** The name applied to a South African shrub, referred to the *Penaceae*, and distinguished from *Penca* by the imbricated arrangement of the lobes of the perianth; by the presence of eight stamens, the anthers of which have not a fleshy connective; and by the pendulous ovules: thus affording a singular illustration of the great difference existing between some plants in certain cases, where nevertheless it is not considered advisable to place them in different groups, because, in spite of their numerous points of diversity, they are yet more closely allied one to the other than to anything else. *G. marginata*, a greenhouse shrub, has red flowers, surrounded by a number of scale-like bracts. [M. T. M.]

**GEISSOMERIA.** A genus of *Acanthaceae*, containing nine species from Brazil. They are undershrubs, with a tetragonous stem, oval or oblong leaves, and long red, often velvety flowers, in many-flowered spikes. These have a five-parted calyx, a tubular corolla dilated upwards, four stamens inserted near the base of the corolla tube, the filaments hairy at the base, and the one-celled anthers acute at both ends. The fruit is oval, and four-seeded. [W. O.]

**GEISSORHIZA.** A genus of South African *Iridaceae*, one species of which has been found in Abyssinia. The plants have bulb-tuberous rhizomes, narrow setaceous or sword-shaped leaves, and a simple or branched stem bearing the large showy flowers in one-sided spikes. The perianth is funnel-shaped, with a short tube, and an ample six-parted nearly equal limb, the segments of which bear a nectariferous pore at the base; the three stamens are included; the style is filiform and declinate, with three linear wedge-shaped conduplicate stigmas; and the ovary is three-celled, with numerous ovules arranged in two rows in the central angles of the cells. The rhizomes are covered by the crustaceous or scarious remains of the bases of the leaves, which lie over each other like the tiles of a roof, and hence the name of Tile-root has been given to the plants. The iris-like

flowers are very showy, and various in colour. [T. M.]

**GELA.** *Entada Purartha*.

**GELASINE.** A genus of *Iridaceae* closely allied to *Trichonema*, with which it is united by many botanists. *G. azurea*, a dwarf bulbous plant from the Rio Grande in South America, is the type. [T. M.]

**GELIDIACEÆ.** A natural order of rose-spored *Alga*: belonging to the group which bears necklaces of spores (*Desmiospermeæ*), and amongst these distinguished by the placenta being axial or suspended by filaments in the cavity of the external or half-immersed capsules. It contains many very beautiful *Alga*, especially in warmer latitudes, amongst which the *Hypnea* are conspicuous, on almost every tropical coast, for the hooked tips of the fronds. *Gelidium corneum*, one of our commonest and most variable seaweeds, with its rigid compressed more or less repeatedly pinnate frond, occurs almost everywhere in some form or other. [M. J. B.]

**GELINEÆ.** Cells in algae secreting vegetable jelly.

**GELL, or GILL.** *Glechoma hederacea*.

**GELSEMIUM.** A genus of *Loganiaceae*, consisting of an evergreen lactescent climbing shrub, found in the vicinity of rivers in the southern states of America. It has opposite lance-shaped shining leaves with small axillary glands, and few-flowered axillary fascicles of sweet-scented yellow flowers, which have a small five-lobed calyx, and a large funnel-shaped corolla, with a five-cleft almost equal limb. The fruit is composed of two separable jointed follicles containing numerous flat seeds. *G. nitidum* is called the Carolina Jasmine. [R. M.]

**GEMINATE.** United or collected in pairs.

**GEMINI.** Two together.

**GEMINIFLOROUS.** When two flowers grow together.

**GEMMA.** A leaf-bud; leaf-buds are sometimes also called *foliifera gemmae*, and flower-buds (*alabastris*), *florifera gemmae*. The term Gemma is also applied to certain small reproductive bodies found in some liverworts, which are regarded as analogous to leaf-buds.

**GEMMATIO.** The act of budding; the manner in which young leaves are folded up in the bud prior to its unfolding.

**GEMMULE.** The plumule; also the ovule.

**GEN.** Persian manna, an exudation caused by insects on the stems of *Tamarix*, according to some authorities; but according to others it is produced by *Alhagi Maurorum*.

**GENDARUSSA.** A genus of *Acanthaceae*, containing a single species, growing everywhere in India. It is a shrub with narrow

leaves, and spicate flowers on axillary pedicels furnished with small bracts and bracteoles. The calyx is regularly five-parted; the corolla tube is short, and its limb two-lipped, with the upper lip arching; there are two stamens, with two-celled anthers; and a slender rigid four-seeded capsule. The leaves and stalk of *G. vulgaris* have, when rubbed, a strong and not unpleasant smell, and are, after being roasted, prescribed in India in cases of chronic rheumatism attended with swelling of the joints. [W. C.]

**GENESTROLLE.** *Genista tinctoria*.

**GENET.** *Genista*. — **BLANC.** *Cytisus albus*. — **D'ESPAGNE.** *Genista juncea*. — **ÉPINEUX.** *Ulex europæus*.

**GENETTE.** (Fr.) *Narcissus Pseudo-Narcissus*.

**GENETYLLIS.** A small genus of *Chamaelauca*, now united with *Darwinia*, having sessile flowers with two small bracts, five short obtuse entire calyx lobes, five ovate slightly acute petals, twenty short stamens, the alternate ones sterile, a filiform bearded style, and a one-celled seed-vessel with four or five seeds. The flower-heads in one section of the genus are enclosed in large coloured ovate or oblong involucre about an inch in length, generally of a reddish hue, or white striped with red, and on this account they are exceedingly handsome plants, particularly *G. tulipifera*, *G. macrostegia*, *G. speciosa*,

*Genetyllis tulipifera*.

and *G. Hookerianna*. The leaves are either lanceolate, spatulate, or linear and three-angled, full of glandular dots, the upper ones generally membranaceous. The name of *Hedaroma* was given by Dr. Lindley to certain of the involucre species from South-West Australia. The species are remarkable for the exquisite sweetness of their foliage, which with the half-ripe fruit retain their fragrance for such a length of time that they possibly might be considered worth collecting for the perfumer. They are mostly heath-like shrubs,

and are natives of the south and south-west parts of Australia. [R. H.]

**GENEVRETTE.** A wine made from juniper berries.

**GENÉVRIER.** *Juniperus communis*. — **A L'ENCENS.** *Juniperus thurifera*. — **CADE.** *Juniperus Oxycedrus*. — **FEMELLE.** *Juniperus tamariscifolia*. — **MÂLE.** *Juniperus cupressifolia*.

**GENICULATE.** Bent abruptly like a knee; as the stems of many grasses.

**GENICULUM.** The node of a stem.

**GENIPA.** A genus of tropical American trees of the cinchona family, nearly allied to *Gardenia*, but differing in the tube of the corolla, which is much shorter than in that genus, so that the five to six ovate segments of the limb are longer than the tube. The fruit is succulent, with a rather thick rind, crowned by the calyx, and tapering at each end. Some of the species furnish edible fruits. Thus *G. americana* produces the Genipap fruit, as large as an orange, and with an agreeable flavour. In Surinam the same fruit is called the Marinalde Box. The fruit of *G. brasiliensis* furnishes a violet dye. A few of the species are in cultivation as evergreen stove plants. [M. T. M.]

**GENIPAP.** The fruit of *Genipa americana*.

**GENIPI BLANC.** *Artemisia Mutellina*. — **NOIR.** *Artemisia spirata*.

**GENIP TREE.** *Genipa*; also an old West Indian name for *Melicocca bijuga*.

**GENISTA.** An extensive genus of leguminous plants, including the *Planta Genista* or *Plante genêt* of the French, from which a celebrated race of English kings, the Plantagenets, took their name, in consequence of their wearing a sprig of the plant as a distinctive badge. The genus contains more than a hundred species, chiefly abounding in the countries bordering on the Mediterranean, in Western Asia, and in the Canary Islands, three being indigenous to Britain. They are all small branching shrubs, sometimes armed with spines, seldom growing higher than five or six feet, and often not more than a foot, bearing simple or trifoliate leaves, and abundant yellow flowers, which are produced either singly or in racemes or clusters from the angles of the leaves or at the ends of the branches. They have a five-toothed calyx; a papilionaceous corolla, of which the keel becomes curved backwards after flowering; ten stamens united into an entire sheath, bearing long and short anthers alternately; and a flattened or sometimes roundish pod constricted between the seeds.

The Petty Whin, *G. anglica*, is a small prickly straggling English shrub, with numerous decumbent stems, bearing small lance-shaped leaves and yellow flowers, and armed with sharp spines, whence the plant is frequently called Needle Green;

weed. *G. tinctoria*, a native of Central and Southern Europe, common in England, is a low bushy tufted shrub, producing numerous woody unarmed stems, which send forth stiff erect angular green branches, clothed with leaves varying from narrow lance-shaped to broadly-elliptical, and bearing short racemes of yellow flowers at the ends of the branches. This was formerly of some importance as a dye plant, but it has long been superseded by dyes of foreign origin. It is commonly known under the name of Woadwaxen or Dyer's Greenweed, but the colour derived from it was a bright yellow, and it was only by afterwards dipping the yellow yarn or cloth into a blue solution of woad (*Isatis*) that the green tint was obtained. This was the process by which was obtained the once celebrated Kendal green, so called from the town of Kendal in Westmoreland, in the vicinity of which the plant was abundant, and where also the process was first introduced by Flemish emigrants in the reign of Edward III. The plant thrives upon very poor soil, and is regarded by agriculturists of the present day as an indication of the poverty of the land where it abounds. [A. S.]

**GENISTELLA.** *Genista anglica*, and others; also *Aspalathus spinosa*.

**GENTIAN.** *Gentiana*. The gentian root of the druggists is furnished by *G. lutea*. —, **BASTARD.** *Hypericum Sarruthra*, or *Sarruthra gentianoides*. —, **HORSE.** *Triosteum*. —, **SPURRED.** *Halenia*.

**GENTIANACEÆ.** (*Gentianwoorts*.) A natural order of corollifloral dicotyledons belonging to Lindley's gentianall alliance of perigenous Exogens. Herbs, rarely shrubs, with opposite entire exstipulate, usually ribbed leaves, and showy flowers. Calyx divided, persistent; corolla persistent, imbricate or induplicate, and often twisted in maturation; stamens alternate with the corolline segments; ovary of two carpels, placed to the right and left of the axis, one-celled with two parietal often introflexed placentas; style one; stigmas two. Fruit a capsule or berry; seeds numerous, with fleshy albumen and a minute embryo. They are found in almost all parts of the world, some at high elevations, and others in hot tropical plains. Bitterness prevails generally in the order. Some of the plants have emetic and narcotic qualities. The root of the yellow gentian of the Alps (*Gentiana lutea*) is used medicinally as a tonic. In the Himalaya, *chirata* (*Agathotes Chirayita*) is employed as a bitter tonic. *Exacum bicolor* and *Ophelia elegans* are similarly used. There are about 70 known genera, and upwards of 500 species. Examples: *Gentiana*, *Suertia*, *Chironia*, *Erythraea*, *Chloria*, *Lisianthus*, *Menyanthes*, *Villarsia*, *Limaanthemum*. [J. H. B.]

**GENTIANA.** A large genus of herbaceous plants, giving their name to the order *Gentianaceæ*. The Gentians are perennial plants, with opposite ribbed leaves; a calyx of four or five valvate segments;

a four to five or occasionally ten-parted corolla; four to five stamens; and a one-celled ovary with two stigmas either separate and rolled back, or contiguous and funnel-shaped. The fruit is a two-valved, one-celled, many-seeded capsule. While blue is the most frequent colour, yet white, yellow, and even red flowers are met with. The red-flowered species are almost confined to the Andes; while blue-flowered species ascend the Himalayas to the height of 16,000 feet. The great majority are found in hilly or mountainous districts, in the northern hemisphere both in the old and new world, extending also to the tropics. Most of the genera which inhabit the elevated regions of the temperate or tropical zones are likewise found in the arctic or antarctic regions in great abundance, but this does not appear to be the case with *Gentiana*.

The abundance and beauty of the Gentians on the European Alps never fail to arrest the attention and demand the admiration of the traveller, who knows not whether most to admire the noble appearance presented by some of the taller more stately-looking species, such as *G. lutea*, or the intensely brilliant blue colour of some of the more lowly-growing species, such as *G. verna* or *acaulis*, and which may be found growing in profusion on little swards environed on all sides by ice-clad rocks and mighty glaciers. A few species are native in the British Islands: the most frequently met with being *G. Amarella*, an erect branching annual, sometimes attaining to the height of ten or twelve inches, the flowers panicled, of a pale purple colour, the calyx with five segments, and the corolla with a fringe of hairs at the throat. *G. campestris* much resembles this, but has the parts of the flower in fours, not in fives, and has two of the lobes of its calyx larger than the other two, which they overlap. *G. Pneumonanthe*, a rare English perennial species, has a stem nearly a foot in height, the upper leaves linear, and the corolla an inch and a half long, bright blue without hairs in its throat, but with five greenish lines on the exterior. *G. verna* is a low-growing perennial, growing in dense tufts with very short flower-stalks, terminated by a single bright blue flower. It is a rare plant in this country, but abundant in mountainous meadows in Central and Southern Europe. *G. nivalis* is only found in Britain on some of the Scotch mountains: it is a slender branching annual, each branch being terminated by a blue flower about half an inch in length. Several of the species are in cultivation, such as *G. lutea*, *G. purpurea*, *G. acaulis* the Gentianella of gardeners, and *G. crinita*, a North American kind, with the four lobes of the corolla fringed at the margin.

It is not only for their beauty that these plants are prized, but for their medicinal properties. All the species are, to a greater or less extent, pervaded by a pure bitter principle, which confers valuable tonic virtues on them, not always unaccompanied by some slight degree of narcotic or acrid

effect. The roots of *G. lutea* are principally used in this country; they are collected in Switzerland and the Tyrol. The roots of *G. purpurea*, *G. punctata*, and *G. pannonica* are used for like purposes; indeed, almost any species might be employed that could be obtained in sufficient quantity. *G. cruciata* has been invested with imaginary virtues, because its leaves grow in the form of a cross; it has been recommended in hydrophobia. The Swiss make a liqueur from some of the species. Some of the Himalayan and North American kinds are used, like the European ones, as tonics. [M. T. M.]

**GENTIANE.** (Fr.) *Gentiana lutea*.

**GENTIANELLA.** A common name for *Gentiana acutis*; also *Orythacanthus barbadensis*.

**GENTIANELLE.** (Fr.) *Exacum*.

**GENTIANWORTS.** Lindley's name for the order *Gentianaceae*.

**GEOCARYUM.** The name of a genus of *Umbellifera*, better united with *Bunium*, but distinguished from it by the styles being more erect, and by the structure of the fruits, which have five ridges, with as many wide oil-channels in the interspaces. In *Bunium*, on the contrary, there are two or three such channels in each interspace. *G. capitifolium* is a native of the south of Europe, Barbary, &c., and has a bulb-like stock, whence the name of the genus, which signifies earth-nut. [M. T. M.]

**GEOCOCCLUS.** A diminutive cruciferous annual stemless herb of Western Australia, throwing out from the neck a series of pinnatifid leaves, from whose axils emerge the minute flowers. After flowering, the peduncles become deflexed, and bury the small seed-vessels about an inch beneath the surface of the ground. [T. M.]

**GEODORUM.** The generic name of a few terrestrial East Indian orchids of the tribe *Vandee*. They have tuberous roots, radical lance-shaped or elliptical leaves six to eighteen inches long, and lateral flower-scapes terminating in a nodding spike of flowers, which in some are of a pale green colour, the lip white and veined with yellow or purple lines, and in others are bluish with a yellow spot on the lip. The sepals and petals are free and connivent; the lip hooded, sessile, and not jointed with the very short column; there are two bilobed pollen-masses with a short caudicle and a transverse gland. *G. dilatatum* and *G. citrinum* are in cultivation. [A. A. B.]

**GEOFFROYA.** A genus of pinnate-leaved South American *Leguminosae* of the tribe *Dalbergieae*, and differing from most in that group in having drupaceous fruits instead of thin dry pods. From *Andira*, to which it is most nearly allied, it differs in the flowers being in simple racemes instead of panicles, and usually yellow with a fetid smell, instead of purple and smelling sweetly; the calyx, also, is distinctly

or deeply instead of obscurely toothed. There are five species enumerated.

*G. superba* is a tree of eighteen to twenty-five feet, with the habit of a tamarind, and is found in Brazil and Venezuela. Its pinnate leaves are four to six inches long; and the yellow fetid pea-flowers are in simple racemes the length of the leaves. The fruits, about the size and form of a walnut, have a greenish-yellow downy rind, a fleshy pulp, and a hard nut or stone enclosing a single seed. Humboldt, in his *Plantes Equinoxiales*, says this is a truly magnificent tree, from the disposition of its branches clothed with beautiful green leaves, as well as from the great abundance of its yellow flowers. According to the same authority, the wood is hard, susceptible of a fine polish, and useful for building purposes, while the fruits are not agreeable, but are eaten by children and much sought after by various animals. Mr. Gardner says the fruits are called *Mari* in various parts of Brazil. He found them to be the principal food of the inhabitants of the Ilha de St. Pedro, who boil them, eating the fleshy portion first, and then the kernel. *Almendra*, or Almond, is a name given to the tree on the Amazon. [A. A. B.]

**GEOGLOSSUM.** A genus of ascomycetous *Fungi* which in outward aspect has the appearance of *Clavaria*, and in consequence has been wrongly associated with the clavate *Fungi*. The whole plant is club-shaped, with the hymenium covering the entire surface of the club except at the base, the distinction between head and stem being generally only slightly marked. There are two distinct groups, those which are black or brown, and those which are green, purple, &c. In the former the sporidia are septate and much elongated, in the latter minute and simple. The species occur in closely-shaven lawns, in grassy pastures, and amongst *Sphagnum* or rottenwood, &c. Occasionally the stem is either viscid and scaly, or densely velvety. No species appears to be esculent. Earth-tongues occur in most temperate parts of the world, but they are more frequent in Europe than elsewhere. [M. J. B.]

**GEONOMA.** A genus of palms closely resembling *Chamadorea* in general appearance, and like these confined to the tropics of the western hemisphere, where they form part of the underwood of dense forests. There are about forty known species, a few of which are stemless, but the generality have slender reed-like polished stems, marked with rings or scars of fallen leaves, and bearing at their summit a tuft of large leaves, which are usually quite entire when young, but afterwards split so as to become irregularly pinnate. The male and female flowers are borne on the same plant, but are sometimes, though not always, on distinct spikes; each spike is enclosed in a double spathe, and is either unbranched or variously branched, the small yellow or purple flowers being seated in little hollows, the males in clusters of two or three, and the females solitary. The

fruits are very small, and contain a single horny seed. None of the species possess any particular features of interest; the only useful purposes to which they are applied being that of supplying leaves for thatching huts, and flexible stems for walking-sticks. [A. S.]

**GEOPHILA.** A genus of *Cinchonaceæ*, called 'earth-loving' from the creeping habit of the plants. The species are natives of tropical America and the East Indies, and somewhat resemble violets in their mode of growth. They are nearly allied to *Psychotria*, from which they are distinguished by their flowers being in heads surrounded by a few bracts, and by the calyx being more deeply divided into five linear spreading segments. [M. T. M.]

**GEORCHIS.** A small genus of orchids found growing among moss, &c., in the damp woods of India and Java. The species have all the habit of *Goodyera*, and, according to Dr. Lindley, differ from that genus in the very sharp-pointed anthers and stigma, the latter of which splits into two long bristle-like arms. The slender stems throw out roots at intervals, and bear a number of ovate or heart-shaped leaves one to three inches in length, while the small white or pink flowers are disposed in terminal spikes. [A. A. B.]

**GEORGINA.** A name given by Willdenow to the genus *Dahlia*, but not generally adopted.

**GEOTHERMOMETER.** A thermometer constructed especially for determining the temperature of the earth.

**GERANIACEÆ.** (*Cranebills*.) A natural order of thalamifloral dicotyledons, characteristic of Lindley's geranian alliance of hypogynous Exogens. Herbs or shrubs with swollen joints, and opposite or alternate leaves, which are usually palmately veined and lobed, often stipulate. Sepals five imbricate, one of them sometimes spurred; petals five, with claws, contorted in bud; stamens usually ten, united by their filaments, some occasionally sterile; ovary of five bi-ovular carpels placed round an elongated axis, to which the styles adhere. Fruit formed of five one-seeded carpels, which finally separate from the base of the central axis or beak, and curve upwards by means of the attached styles; seed exalbuminous; embryo curved and doubled up, with platted cotyledons. The plants are distributed over various parts of the world. The species of *Pelargonium* abound at the Cape of Good Hope; those of *Geranium* and *Erodium* are chiefly natives of Europe, North America, and Northern Asia. They have astringent and aromatic qualities, many of them are fragrant, and some have a musky odour. They are sometimes tuberous, and the tubers are eaten. There are numerous hybrids among the plants of this order, and it is not easy to determine the exact number of species, but about 540 are recorded. *Erodium*, *Geranium*, *Pelargonium*, and *Monsonia*, are ex-

ample. [J. H. B.]

**GERANIUM.** The Cranebills, whose name is derived from the long central beak of the fruit, form a large genus of the *Geraniaceæ*, distinguished by having regular flowers, ten stamens with the filaments united at the base, and five carpels each tipped by a long glabrous awn (the persistent style), which becomes recurved when it separates from the central axis, not spirally twisted as in *Erodium*. They are herbs, very rarely undershrubs, growing in all temperate climates, having stems with enlarged joints and palmately lobed cleft or divided leaves, the lower ones stalked, the upper sessile. The one or two-flowered peduncles have small bracts at the base of the pedicels, and the flowers are often large and brightly coloured. Most of the species are astringent, particularly the North American *G. maculatum* or Alum-root, the rhizome of which is used in its native country instead of kino. The Tasmanian *G. purpureum* is there called the Native Carrot, and its tubers used as food. There are about a dozen British species. The genus *Pelargonium*, to which belong the popular Geraniums of our gardens, is distinguished from the Cranebills, by its irregular flowers, and adherent calycine spur. [J. T. S.]

**GERANIUM, INDIAN.** A term used by perfumers for *Andropogon Nardus*. —, **NETTLE.** A popular name for *Coleus fruticosus*.

**GERANION.** (Fr.) *Geranium*, including *Pelargonium* and *Erodium*.

**GERARDIA.** A genus of *Scrophulariaceæ*, consisting of annual or perennial herbs, rarely shrubby at the base, and most if not all the species probably more or less parasitical on the roots of other plants. The leaves are opposite, or the upper ones alternate, all entire or very rarely cut. The flowers, sessile or pedicellate in the upper axils, or forming short terminal racemes, are usually purple or pink, and downy outside. The calyx is campanulate and five-toothed; the corolla obliquely tubular or campanulate, with five broad more or less spreading lobes; the stamens four, didynamous, not longer than the corolla, with two-celled anthers. The capsule opens loculicidally in two valves, and contains numerous small seeds. There are about two dozen species known, natives of North or South America, and most of them very handsome. All attempts to cultivate them have, however, failed. The dried specimens usually turn quite black.

**GERBE-D'OR.** (Fr.) *Solidago canadensis*.

**GERBERA.** A genus of that group of the *Compositæ* called *Mutisaceæ*, in which all the florets are two-lipped. The genus is almost entirely African, and is represented in greatest numbers at the Cape. Upwards of a dozen species are known, all stemless perennial herbs, with their leaves

usually clothed beneath with white cottony down; some, as *G. asplenifolia*, have pinnatifid leaves, calling to mind the fronds of *Asplenium Trichomanes*, but the larger proportion have the leaves oval or oblong and entire. The flower-stalk which rises from the crown bears on its apex a single large flower-head one to two inches across, the ray florets in which are yellow, purple, or blood colour, disposed in a single or double row, and containing a pistil only, while the disk florets are usually yellow and perfect. The achenes are cylindrical or flattened, smooth, beaked, and crowned with a pappus of two or more series of rough hairs. The name *Lastopus* is by some authors given to those species which have a double row of ray florets. [A. A. B.]

GERMANDER. *Teucrium Chamædrys*; also a common name for the genus *Teucrium*. —, WATER. *Teucrium Scordium*. —, WOOD. *Teucrium Scorodonia*.

GERMANDRÉE. (Fr.) *Teucrium*. — AQUATIQUE. *Teucrium Scordium*. — FEMELLE. *Teucrium Botrys*. — MARITIME. *Teucrium Marum*. — OFFICINALE. *Teucrium Chamædrys*. — SAUVAGE. *Teucrium Scorodonia*.

GERMAN TINDER. The Soft Amadou, *Polyporus fomentarius*.

GERMEN. The ovary.

GERMINATION. The first act of growth by an embryo plant, connected with the absorption of oxygen and the extrication of carbonic acid. Germination ceases when the latter begins to be decomposed.

GERNOTTE. (Fr.) *Buntium Bulbocastanum*.

GÉROFLE, or GÉROFLIER. (Fr.) *Caryophyllus aromaticus*.

GERONTOGEIOUS. Of or belonging to the Old World.

GEROPOGON. A genus of the composite family nearly related to *Tragopogon*, and consisting of an annual glabrous herb of the south of Europe, having simple stems, subamplexicaul entire elongated leaves, and capitules of purplish flowers solitary at the thickened apex of the stem. It differs from *Tragopogon* in having hair-like scales on the receptacle, and in the nature of the pappus. [T. M.]

GERVAO. A Brazilian name for *Stachytarpha jamaicensis*.

GESNERACEÆ. (*Cyrtandraceæ*, *Didymocarpeæ*, *Gesneriops*). A natural order of corollifloral dicotyledons belonging to Lindley's bignonioid alliance of perigynous Exogens. Herbs or shrubs often growing from scaly tubers, with wrinkled usually opposite leaves and showy flowers; calyx half-adherent five-parted; corolla more or less irregular, five-lobed; stamens two, or four and didynamous with the rudiment of a fifth, the anthers often combined. Ovary one-celled, surrounded at the base by glands or a ring. Fruit capsular or

succulent, one-celled, with parietal placentas to the right and left of the axis. Natives of various parts of the world, chiefly the warmer regions of America. The succulent fruits are occasionally edible, and some of the species yield a dye. The leaves of some of them produce buds when laid on the soil. There are upwards of 80 genera, and nearly 300 species. *Gesnera*, *Glazinia*, *Achimenes*, *Streptocarpus*, and *Cyrtandra* furnish examples. [J. H. B.]

GESNERA. The typical genus of *Gesneraceæ*, consisting of numerous tropical South American species, some of which are amongst the most beautiful of the herbaceous plants cultivated in our stoves. It has, like some other genera of the order, been much broken up by modern botanists. Some of the species are referred to a division called *Brachylomateæ*, in which there are squamose catkin-like stamens, as in *Achimenes*; others to the *Eugenerææ*, which have tuberous rhizomes; and others to the *Rhytidophylleæ*, which are shrubby or subshrubby in habit. In the modern restricted form, *Gesnera* itself consists of plants with depressed tubers, a racemose corymbose or paniced inflorescence, and somewhat two-lipped corollas, much longer than the calyx, and with a short galea or upper lip, differing in the latter particular from *Durcea*, another of the *Eugenerææ*, in which the upper lip is very much elongated and fornicate. The flowers have also from two to five conspicuous glands. Of the five groups into which the restricted genus is divided, the following species are examples: *G. discolor*, *macrostachya*, *tuberosa*, *Scieptrum*, and *punctata*. The most familiar of the separated genera in the several tribes are the following, the first three of which belong to the *Brachylomateæ*, the next two to the *Eugenerææ*, and the remainder to the *Rhytidophylleæ* :—

*Negelia*: with a campanulate-cylindrical corolla tube, inflated beneath, and short subbilabiate limb, a five-crenate perigynous glandular ring, and a stomatomorphous stigma: ex. *G. zebrina*.

*Kohleria*: with an oblique corolla having a cylindrical or tumid deflexed tube, and ringent limb, five subequal glands, and a bifid stigma: ex. *G. Seemannii*.

*Cryptoloma*: with a straight corolla tube, and very short limb, five subequal glands, and a bifid stigma: ex. *G. hondensis*.

*Reichsterneria*: with a subbilabiate tubular corolla, two large dorsal glands and three smaller ventral ones, and a stomatomorphous stigma: ex. *G. allagophylla*.

*Durcea*: with a gaping tubular corolla, the upper lip elongate-fornicate, the lower truncate, two connate dorsal glands, and a stomatomorphous stigma: ex. *G. bulbosa*.

*Houltea*: with a long corolla tube, and short spreading limb, and five glands, of which the dorsal are larger and connate: ex. *G. pardina*.

*Moussonia*: with a shorter subinflated corolla tube, and scarcely spreading limb, and five subequal glands: ex. *G. elongata*.

*Horticola*: with a very long slightly curved corolla tube, and straight limb, and a five-lobed toothed ring: ex. *G. libanensis*. [T. M.]

GESNERIE BIZARRE. (Fr.) *Tydas picta*.

GESNERWORTH. A name proposed by Lindley for the *Gesneraceae*.

GESSE. (Fr.) *Lathyrus*. — CHICHE. *Lathyrus Cicera*. — DE PRÉS. *Lathyrus pratensis*. — GRANDE. *Lathyrus latifolia*. — SAUVAGE. *Lathyrus sylvestris*. — VELUE. *Lathyrus hirsutus*.

GESSETTE. (Fr.) *Lathyrus Cicera*.

GETHYLLIS. A small genus of Cape *Amaryllidaceae*, allied to *Sternbergia* and *Oporanthus*, and consisting of dwarf bulbous plants, with linear leaves, and short one-flowered flower-scapes. The perianth tube is long cylindrical, the limb of six segments regular and spreading; the stamens inserted in the mouth of the tube, and sometimes by superfluity doubled or trebled or multiplied numerous, with erect anthers; and the style connate with the perianth tube, free and exserted at top, with a capitate trigonous stigma. The capsule is berry-like and succulent, and is said to be caeculent. *G. undulata* has the leaves remarkably waved at the edge, and ciliated with strong bristles. [T. M.]

GEUM. A genus of perennial *Rosaceae*, deriving its generic name from the Greek word *geuo*, which signifies to have an agreeable taste, on account of the slightly aromatic flavour of the roots of some of the species. The main characters of the genus reside in the calyx, whose limb is five-cleft, with five little bracts on the exterior, and in the carpels which are dry with hardened hooked styles forming collectively a kind of burr. Two species are natives of Britain, *G. urbanum* and *rivale*. The former, known as Avena or Herb Bennet, has an erect slightly branched stem; the lower leaves deeply divided in a pinnate manner, with a large terminal lobe, the side lobes in pairs, some of them much smaller than the rest; the flowers yellow, with small spreading petals. The root of this plant, called by the old herbalists Clove-root, *radic caryophyllata*, has an aromatic clove-like odour, and, as it possesses astringent properties, it has been used in diarrhoea, dysentery, intermittent fevers, &c. It was formerly put into ale to give it a clove-like flavour and prevent it turning sour, and has been recommended to be chewed when the breath is foul. The Water-avens, *G. rivale*, has the leaves more hairy, the flowers much larger, drooping, and of a dull purple colour, and the head of fruits separated from the calyx by a short stalk. This plant is frequently found in a prolied state, that is, with a branch or a second flower in the centre of the original one. Other species of this genus are widely diffused over the temperate regions of the northern hemisphere. *G. canadense* is found in Canada and the United States,

where it is known by the name of Choccolate or Blood root, and is used as a mild tonic. Several species are cultivated in this country: among the handsomest is *G. coccineum*, with scarlet flowers. [M. T. M.]

GEVIN. (Fr.) *Quadrifida*.

GHEKOOL, or GHET-KOL. An Indian name for the acrid tubers of *Typhonium trilobatum*.

GHETCHOO. An Indian name for *Aponogeton monostachyon*, the tubers of which are used like potatoes.

GIBBER. A pouch-like enlargement of the base of a calyx, corolla, &c.

GIBBEROSE, GIBBOUS, or GIRBOSE. More convex or tumid in one place than another.

GIESEKIA. A genus of *Phytolaccaceae*, containing tropical or subtropical annual herbs from Asia and Africa, with prostrate dichotomous stems, linear-oblong or spatulate entire fleshy leaves, rough with subcutaneous glands, and small greenish flowers, often becoming purple, in small umbellate or contracted cymes opposite the leaves. The fruit consists of three to five rough utricles. The name is sometimes written *Gieskia*. [J. T. S.]

GIESLERIA. A gesneraceous plant of herbaceous habit, now included in *Tydas*.

GIGARTINA. A genus of the large natural order of rose-spored *Algae*, called *Cryptonemiaceae*. The capsules, which are globose and external, contain several roundish masses of spores; the frond is flat or cylindrical and mostly branched, composed of innumerable longitudinal and horizontal threads in a firm pellucid jelly; and the tetraspores are collected in little heaps or sori. The genus is very nearly allied to *Iridaea* and *Chondrus*. Many of the species are covered with projecting tubercular or spine-shaped processes, so as to make the frond rough like a rasp. *G. mamillata* is often found amongst carageen. *G. speciosa*, the Jelly-plant of the Australian colonists, is now referred to *Eucheuma*. [M. J. B.]

GIGOT. (Fr.) *Iris fatioides*.

GILIA. A genus of American *Polemonidaceae* containing about sixty-five species. The corolla is infundibuliform and hypocrateriform, sometimes almost campanulate or rotate; the five stamens are equally inserted in the throat or tube of the corolla; the ovules few or many in each cell. Dr. Asa Gray divides the genus roughly into three groups, characterised mainly by their foliage: — 1. *Gilia*, with alternate pinnately cut or divided leaves; 2. *Lepodactylon*, frutescent plants with nearly the corolla of *Phlox*, and alternate pinnately parted leaves; 3. *Leposiphon*, annuals with opposite palmately divided (or entire) leaves. To this division the seeds in some sort answer; but the characters do not hold good throughout. Those of the first group are mostly mucilaginous and spirilliferous, as in *Collomia*, *Sponopeltis*, *Femelia*, and *Novarettiella* are united with *Gilia* by Dr. Gray. Many pretty species are cultivated in our gardens, as *G. (Sponopeltis)*

*coronopifolia*, *G. tricolor*, and *G. capitata*, the last an annual with dense heads of small blue flowers, at first sight resembling those of *Jasione*. A very beautiful variety of *G. micrantha* has lately been introduced to cultivation under the name of *Leptosiphon roseus*. [J. Br.]

**GILBERTIA.** A genus of ivy-works, characterised by having the corolla with five to ten petals; stamens five to ten, attached to the petals and alternate with them; style short, rising in five to ten stigmas, which are at first erect, and then spreading. The genus was named in honour of J. E. Gilbert, a French botanist. There are two or three species, natives of Tropical America, having alternate oblong acute leaves, slightly toothed; and flowers in terminal compound umbels. [G. D.]

**GILL, or GELL.** *Nepeta Glechoma*.

**GILLENIA.** A genus of perennial herbaceous plants belonging to the *Ronaceae* and allied to *Spiraea*, from which, however, it is well distinguished by its funnel-shaped calyx, very short stamens, and five carpels combined into a five-celled capsule, with two seeds in each cell. The leaves are ternate, with stalked serrated leaflets; the flowers whitish or red, axillary and terminal, on long flower-stalks. The roots are medicinal, possessing in a mild degree the properties of *Ipécacuanha*. Two species only are described by botanists, both natives of North America: *G. trifoliata*, distinguished by its very narrow pointed stipules; and *G. stipulacea*, the stipules of which are large, ovate and deeply cut. [O. A. J.]

**GILLIESIACEÆ.** (*Gilliesiads*.) A natural order of hypogynous monocotyledons belonging to Lindley's liliac alliance of Endogens. Bulbous plants, with grass-like leaves, and umbellate flowers enclosed in a spathe. Perianth of two portions, the outer petaloid and herbaceous, six-leaved, the inner minute often five-toothed; stamens six, three sometimes sterile. Capsule three-celled, three-valved, many-seeded, opening in a loculicidal manner; covering of seed black and brittle; embryo curved; albumen fleshy. Natives of Chili. The genera are *Gilliesia* and *Miersia*, comprising about half a dozen species. [J. H. B.]

**GILLIESIA.** A genus of Chilean bulbous herbs, belonging to *Gilliesiaceæ*. They have linear flaccid root-leaves, and sub-decumbent scapes, the flowers numerous, greenish, inconspicuous, in an umbel with two leaf-like bracts at the base. The exterior involucre is five-leaved, with the two lateral interior ones much smaller than the others; the interior involucre many-leaved, surrounding a slipper-like perianth lobe; the stamens are united into a cup, the three posterior ones sterile. [J. T. S.]

**GILLIFLOWER.** A name corrupted from the French *Giroflée*; also written *Gilloflower* and *Gillyflower*, and further corrupted into *July-flower*; that of the old writers was *Dianthus Caryophyllus*, of the moderns, *Matthiola*. — **CLOVE.** *Dianthus Caryophyllus*. — **MARSH.** *Lychnis Flos cuculi*. — **QUEEN'S.** *Hesperis matronalis*.

— **ROGUE'S.** *Hesperis matronalis*. — **SEA.** *Armeria vulgaris*. — **STOCK.** *Matthiola incana*, annua, &c. — **WALL.** *Cheiranthus Cheiri*. — **WATELI.** *Hottonia palustris*. — **WINTER.** *Hesperis matronalis*.

**GILLS.** The lamellæ or plates growing perpendicularly from the cap or pileus of an agaric.

**GILVUS.** Dull yellow, with a mixture of grey and red.

**GINGELLY OIL.** The oil of *Sesamum orientale*.

**GINGEMBRE.** (Fr.) *Zingiber*.

**GINGER-GRASS OIL.** An essential oil obtained from *Andropogon Nardus*.

**GINGER.** *Zingiber officinale*. The ginger of the shops is the dried rhizomes of this plant; black or East Indian ginger is the unscraped rhizome prepared by scalding; white or Jamaica is the scraped rhizome dried in the sun. — **AMADA.** *Curcuma Amada*. — **EGYPTIAN.** *Colocasia esculenta*. — **INDIAN.** *Asarum canadense*. — **MANGO.** *Curcuma Amada*. — **RED.** The same as East Indian ginger. — **WILD.** *Asarum canadense*. — **WOOD.** An old name for *Anemone ranunculoides*.

**GINGERBREAD-TREE.** The *Domn Palm*, *Hyphane thebaica*; also *Portulacium macrophyllum*.

**GINGERWORDS.** A popular name for the *Zingiberaceæ*.

**GINGILIE OIL.** The oil of *Sesamum orientale*.

**GINGO, or GINKGO.** The aboriginal Japanese name of *Salisburia adiantifolia*.

**GINSEN.** (Fr.) *Panax*.

**GINSENG.** The root of one or more species of *Panax*. It is also called *Ginschen*. Pereira gives *P. quinquefolium* as American Ginseng, and *P. Schinseng* as Asiatic Ginseng.

**GIPSWORT.** *Lycopus europæus*.

**GIRANOLEE.** (Fr.) *Coburgia*.

**GIRARDINIA.** A genus belonging to a small group of the nettle family, characterised by its stinging properties. From *Urtica* itself it differs in having alternate instead of opposite leaves, and from other allies in the calyx of the fertile flowers being two-parted, one of the segments being much the larger and three-toothed, the other small, linear, or sometimes abortive. The species, three of which are East African and three East Indian, are tall annual or perennial herbs, having all their parts clothed with long and sharp white stinging hairs. The stalked leaves, which are accompanied by large stipules, are sometimes nearly a foot in length, variously lobed and coarsely toothed, some like those of the hemp, others like those of the maple in form. The small green flowers, like those of a nettle, are unisexual; the males in racemes and the females in compact

cymes, densely clothed with stinging hairs. *G. heterophylla*, one of the commonest Himalayan species, has three to seven lobed leaves, five inches to a foot long. Dr. Hooker, in his *Himalayan Journals*, alluding to this plant, says: 'The quantity of gigantic nettles growing on the border of maize fields was quite wonderful; their long white stings look most formidable, but, though they sting powerfully, the pain only lasts half an hour or so.' According to the same authority, a sort of cloth, and also a sort of cordage, are made from fibre furnished by the stems of this plant in Sikkim. In Southern India, the stems of *G. Leschenaultiana*, which is closely allied to the preceding, yield a good silken fibre which is made into thread. The process of separation, in some places, is performed by boiling the stems; in others, by steeping them in water for twelve days or so, when the outer or fibrous portion is readily removed, and afterwards spun into a beautiful soft thread. The fibre exists in large proportions, and the tow bears great resemblance to sheep's wool. [A. A. B.]

**GIRAUMONT.** (Fr.) *Cucurbita Pepo*. The seeds of some cucurbitaceous plant, bearing the name of Giraumont seeds, are used to destroy tape-worm.

**GIREODIA.** A genus of *Begoniaceæ*, named after M. Gireoud, a Berlin horticulturist. Flowers monœcious: the staminate ones with two obovate petals, numerous stamens of nearly equal length, and oblong anthers opening laterally; the pistillate ones with two petals, a trigonal inferior three-celled ovary which is unequally winged, and crescentic stigmas surrounded at the margin by a papillose band. The capsule is triquetrous and top-shaped, opening by curved chinks at the origin of the wings. They are fleshy undershrubs, erect or creeping, found in Central America and in Mexico, and have usually entire lobed leaves with long petioles and large stipules. The flowers are in axillary dichotomous cymes. There are about thirty species, all of which were formerly included in *Begonia*. [J. H. B.]

**GIROFLÉE.** (Fr.) *Cheiranthus*. — **DES JARDINS.** *Matthiola incana*. — **DE MAHON.** *Malcolmia maritima*. — **DE MURAJLE.** *Cheiranthus Cheiri*. — **JAUNATRE.** *Cheiranthus ochroleuca*. — **JAUNE.** *Cheiranthus Cheiri*. — **QUARANTAINÉ.** *Matthiola annua*. — **VIOLETTE.** *Cheiranthus Cheiri*.

**GIROFLIER,** or **G. AROMATIQUE.** (Fr.) *Caryophyllus aromaticus*.

**GIROLLES.** (Fr.) *Sam Sisarum*.

**GIROSELLE.** (Fr.) *Dodecatheon*.

**GITH.** The Corn Cockle, *Agrostemma Githago*.

**GITHAGINEUS.** Greenish-red.

**GITHAGO.** The name of one of the groups included in *Lychnis*, and represented by the *Agrostemma Githago* of Lin-

næus. The lamina of the petals is entire and without appendages. [T. M.]

**GITHOPSIS.** A genus of *Campanulaceæ*, nearly allied to *Specularia*, but differing in the narrow-campanulate, not rotate, corolla, in the filaments without hairs, and in the capsule opening in terminal pores. It comprises two Californian annuals, with small blue flowers, scarcely showing between the long segments of the calyx.

**GLABER, GLABRATE, GLABROUS.** Smooth; having no hairs.

**GLACIALE.** (Fr.) *Mesembryanthemum crystallinum*.

**GLADDON, GLADEN, or GLADER.** *Iris fastidissima*.

**GLADIATE.** Sword shaped; the same as *Ensiform*.

**GLADIOLE, WATER.** *Butomus umbellatus*.

**GLADIOLUS.** An extensive and very beautiful genus of *Iridaceæ*, found sparingly in the warmer parts of Europe and in the Mediterranean region, and much more abundantly in South Africa. They form fleshy corms, from which grow the erect stems, terminating in a spike of flowers of greater or less length, the leaves being distichous and equitant, and either narrow and grass-like or rush-like, or broader and sword-shaped. The flowers consist of an irregular perianth, with a terete tube, and six parted bilabiate limb; three stamens inserted in the tube; and an obtusely three-cornered three-celled ovary, containing numerous ovules in several rows in the central angle of the cells. The ovary is crowned by a filiform style, with three petaloid stigmas. There is great variety amongst the species, not only in aspect, but also in size, and in the form of the flowers. Certain of them, chiefly *G. natalensis*, *floribundus*, and *cardinalis*, have, by cross-breeding and continued seeding, yielded a race of half-hardy so-called bulbs, which rank amongst the most ornamental of our popular garden flowers, and of which new varieties are raised annually in large quantities. These are all stately plants, growing from three to six feet in height, and producing long spikes of large blossoms of the most varied and striking colours. The European species are hardy garden flowers in favourable situations. [T. M.]

**GLADWYN.** *Iris fastidissima*.

**GLAIVANE.** (Fr.) *Xiphidium*.

**GLAND DE TERRE.** (Fr.) *Lathyrus tuberosus*.

**GLANDACEUS.** Yellowish-brown, the colour of an acorn.

**GLANDS, GLANDULES.** Wart-like swellings found on the surface of plants, or at one end of their hairs. They are extremely various in form.

**GLANDULOSE, GLANDULIFEROUS.** Bearing glands.

**GLANDULOSO-SERRATE.** Having serratures tipped by glands.

**GLANDULAR.** Covered with hairs bearing glands upon their tips; as the fruit of roses, the pods of *Adenocarpus*, &c.

**GLANS.** An inferior fruit, one-celled by abortion, not dehiscing, containing one or two seeds, and seated in a cupule; as in the acorn.

**GLAPHYRIA.** A genus of myrtaceous shrubs, natives of the Malayan islands, &c. The limb of the calyx is five-lobed; petals five, fruit succulent, with five many-seeded compartments. *G. nitida* is called by the Malays the Tree of Long Life, probably because it is enabled to grow at greater elevations than other forest trees. The leaves are used as a substitute for tea. [M. T. M.]

**GLAREOSE.** Growing in gravelly places.

**GLASSWORT.** *Salicornia*. —, **PRICKLY.** *Salicornia Kali*. —, **WHITE.** *Suaeda maritima*.

**GLAUDESCENT.** Dull green, passing into greyish-blue.

**GLAUCIUM.** A genus of herbaceous plants belonging to the *Papaveracea*, well marked by their very long pod-like two-valved and two-celled capsule. The Yellow Horn Poppy, *G. luteum*, is a common plant on the sandy sea-shore of Europe and some parts of North America, where it may be detected even in winter by its large, rough, deeply-cut leaves of a decided glaucous hue. In summer it attains the height of about two feet, and is made conspicuous not only by the white hue of its foliage, but by its large flowers of four delicate pale-yellow petals, which last only for a day, and are succeeded by very long curved pods, which are rough with tubercles. *G. pharuceum*, a smaller species, with scarlet flowers, and a black spot at the base of each petal, is said to have been found in England, but is not considered a native. Several other species, with yellow or scarlet flowers, are cultivated, and are considered ornamental plants; they are either annual or biennial, and abound in a copper-coloured acid juice, which is said to be poisonous and to occasion madness. German, *Gehörnte schelkraut*. [C. A. J.]

**GLAUCOUS.** Covered with a fine bloom, like that of the plum or the cabbage-leaf.

**GLAUX.** A pretty little herbaceous perennial, belonging to the *Primulaceae*. The flower is destitute of a corolla, but the bell-shaped calyx is coloured and five-lobed; the capsule is globose, five-valved, and contains about five seeds. *G. maritima*, the only species, grows abundantly on most parts of the sea-coast, just above high-water mark, and in salt marshes. The roots, which creep extensively, are composed of long zigzag fibres, and send up numerous matted stems, four to five inches high, and densely clothed with oblong fleshy smooth

entire leaves, which are pale underneath and salt to the taste. The flesh-coloured flowers are solitary, nearly sessile, and axillary. The glaucous hue of the leaves sufficiently accounts for the systematic name; but whence it derived one of its English names, Sea Milkwort, is not so plain. Another name, which is appropriate enough, is Black Saltwort. French, *Glauce*; German, *Milchkraut*. [C. A. J.]

**GLAYEUL.** (Fr.) *Gladiolus communis*. — **PUANT.** *Iris fetidissima*.

**GLEBA, GLEBULA.** The peridium or the fleshy part of certain fungi.

**GLEBULÆ** (adj. **GLEBULOSE**). Little roundish elevations of the thallus of lichens; also the spores of certain fungi.

**GLECHOMA.** The Linnæan generic name of *Nepeta Glechoma* and other allied species of *Nepeta*. *G. hederacea*, Ground Ivy, is a well-known trailing herbaceous plant, with kidney-shaped crenate leaves and violet-purple flowers; formerly much esteemed for its supposed medicinal virtues. Its leaves are slightly bitter and aromatic, on which account it was used to give a flavour to ale; hence its old names Ale-hoof and Tun-hoof. The juice was recommended to be dropped into the ears to cure singing in that organ; mixed with wine, and dropped into the eyes, it was supposed to cure inflammation; taken as snuff, it was a specific for a head-ache; and an extract or decoction, mixed with honey or sugar-candy, was a favourite remedy in complaints of the chest. Village herbalists still hold it in repute, and use it, when dried, as a substitute for tea. Gerard enumerates among its other virtues, that, 'boiled in mutton-broth, it helpeth weak and aking backs;' a prescription which many modern physicians would no doubt endorse, if administered with the same accompaniment. French, *Terrete*; German, *Gundelreben*. [C. A. J.]

**GLECHON.** A genus of plants of the labiate order, distinguished by the tube of the corolla being as long as the calyx; the two lower stamens only present and fertile; and the style bifid at the apex, the upper lobe very short, the lower long and compressed. The species are Brazilian shrubs of humble growth, having the leaves usually small, the flowers in groups varying from two to six, and red, blue, or yellowish in colour. [G. D.]

**GLEDITSCHIA.** A small genus of thorny leguminous trees, inhabiting various parts of North America and China. They have once or twice pinnated leaves, and small dense spikes of inconspicuous greenish flowers, some of which are perfect, while others are of one sex only. The pod is flat, and contains either one or several flat seeds, surrounded by a sweet pulpy substance, and separated from each other by transverse divisions. The three-thorned Acacia, or Honey-locust tree, *G. triacanthos*, is a native of the United States, and is commonly cultivated, both there and in

this country, as an ornamental tree. It grows from fifty to eighty feet high, sending forth large spreading branches, and while young both stem and branches are fearfully armed with stout, usually triple, thorns, tapering to very sharp points; but as the tree increases in size these thorns are principally confined to the smaller branches. In the autumn the trees bear numerous long thin and flat pendulous pods, which are usually curved and often twisted, and have been compared to 'large apple-parings, pendent from the branches.' They are sometimes as much as a foot and a half long, and contain numerous seeds, enveloped in a sweet pulpy substance, from which a kind of sugar is said to have been extracted. The wood is coarse-grained, very hard, and splits easily, but is not much employed except for fences and similar purposes. *G. monosperma*, the Water-locust of the Southern United States, is a very large tree, closely resembling the last in general appearance, but its flat pods are small and nearly oval, and contain only one seed. [A. S.]

**GLEICHENIACEÆ.** A group or sub-order of Ferns, remarkably distinct in aspect from other ferns. They belong to the long series which is distinguished by the spore-cases having a jointed ring, and bursting irregularly instead of being valvate; but the spore-cases are sessile, and the ring is more or less strictly horizontal, and consequently the fissure made by their bursting takes a vertical instead of the more usual horizontal direction. The additional features of rigid opaque fronds and oligocarpous dorsal sori complete the distinctive marks of the group, of which *Gleichenia* is the principal genus. [T. M.]

**GLEICHENIA.** A genus of polypodiaceous Ferns, typical of the tribe *Gleicheniææ*. They are furnished with creeping rhizomes, rigid usually often repeatedly dichotomously forked fronds, with the ultimate branches pinnatifid, and either bearing small rounded or ovate segments, or larger linear ones resembling the teeth of a comb. The sori are naked, sometimes placed in a hollow space, oligocarpous, that is, consisting of but few spore-cases, the number varying from two to four in one group, and from eight to twelve in another. The latter series, which agrees with that having the linear segments, forms the group *Mertensia*, which some pteridologists regard as a distinct genus. There are many species scattered widely in the tropics both of the Old and New World, and extending to Chili and the Australasian region. [T. M.]

**GLI.** An intoxicating liquor prepared by the Hottentots from *Lichensteinia pyrethrifolia*.

**GLIDEWORT.** *Galeopsis Tetrahit*.

**GLINUS.** A genus usually referred to *Mesembryaceæ*, but considered by A. Richard, as belonging to the tribe *Molluginææ*. They are

annual prostrate branched herbs, rarely undershrubs, growing in tropical and sub-tropical regions, a single species occurring in the south of Europe. Leaves alternate or falsely verticillate; flowers inconspicuous, with a five-cleft calyx; the corolla absent, or with numerous very narrow strap-shaped petals, and three to twenty stamens. [J. T. S.]

**GLOBBA.** A genus of tropical Asiatic herbaceous plants belonging to the *Zingiberaceæ*, and having a terminal loosely-clustered inflorescence, the flowers of which have a three-cleft tubular calyx; a corolla with a slender tube and a six-parted limb, the three outer divisions equal, and two of the inner ones narrow or very small, while the remaining one, or lip, is large, undivided, and partly united with the filament in a tubular manner. The ovary is one-celled. They are handsome plants, with angular-looking yellow or pinkish flowers; some of them grown in this country as stove plants. The fruit of *G. uniformis* is said to be edible. [M. T. M.]

**GLOBE-FLOWER.** *Trollius*; also *Gomphrena globosa*.

**GLOBOSE.** Forming nearly a true sphere.

**GLOBULAIRE.** (Fr.) *Globularia vulgaris*.

**GLOBULARIACEÆ.** A natural order of corollifloral dicotyledons, belonging to Lindley's cephial alliance of perigynous Exogens. Lindley unites *Selaginaceæ* with this order, but De Candiolle separates them. A small group of herbaceous or shrubby plants with alternate exstipulate smooth leaves, and capitate flowers surrounded by an involucre. Calyx five-divided with quinque-lobed; corolla tubular, lipped, five-lobed; stamens four, inserted into the upper part of the tube of the corolla, the anther becoming one-celled, and opening by a single longitudinal slit. Ovary free, one-celled; ovule one, pendulous anatropal. Fruit an achene, enclosed by the calyx; seed with fleshy albumen; embryo with a superior radicle. Natives of Europe, and of the parts of Asia and Africa nearest Europe. There are but few species, distributed in the genera *Currodoria* and *Globularia*. [J. H. B.]

**GLOBULARIA.** A genus containing a few species of herbs, shrubs, or undershrubs, natives of the countries bordering on the Mediterranean Sea. They have alternate entire spatulate leaves, and flowers collected upon a common receptacle, and surrounded by a many-leaved involucre. The calyx is unequally five-cleft; the corolla tubular, with the limb two-lipped, the upper lip bipartite and smaller than the lower, which is trifid; and there are four stamens, inserted at the top of the corolla tube. The ovary is composed of a single carpel, and contains a single pendulous anatropal ovule. This genus differs from the *Selaginaceæ*, in having the ovary formed of a single carpel, as well as in its habit, in both of which respects it agrees

with *Dipsacaceæ*, but the plants of this order have an inferior ovary. [V. G.]

**GLOBULEA.** Succulent plants, natives of the Cape, with flat or sickle-shaped leaves, arranged in a rosette. The flowers are small, arranged in dense clusters, and have five petals bent inwards, each of them tipped with a little globule of waxy matter, whence the name of the genus, which differs little from *Crassula*, save in the direction of the petals. Several kinds are in cultivation. [M. T. M.]

**GLOBULINE.** Elementary cells; starch grains.

**GLOBULUS.** A kind of perithecioid occurring among fungi; the antheridium of *Chara*; also, a round deciduous shield, found in such lichens as *Isidium*, formed of the thallus, and leaving a hole where it falls off.

**GLOCHIDION.** A genus of the spurwort family, comprising upwards of fifty species of shrubs or small trees, for the most part found in India, a few extending eastward to Japan; others occurring in tropical Australia and the adjacent islands, and three being natives of West Africa. From *Phyllanthus*, to which they are closely allied, they differ in the flowers being destitute of a glandular disk, and generally in the more numerous cells of the ovary. Their alternate leaves are often arranged in a distichous manner; the blades of some of them have a metallic lustre, while others are clothed with soft short down. Their inconspicuous yellow or green flowers are male and female on the same plant, disposed in axillary clusters, the males usually occupying the circumference and the females the centre, both having a five or six-parted calyx. The fruits are globular or depressed capsules, sometimes covered with a thin and fleshy red coat, but more often quite dry; when ripe they split into three to ten portions. The bark of *G. nitida* is said by Roxburgh to be astringent. *Bradleya* and *Gynoon* are now referred to this genus. [A. A. B.]

**GLOCHIS** (adj. **GLOCHIDATE**). Hooked back at the point, like a fish-hook.

**GLOTOCARP.** The quadruple spore or tetrachocarp of some algae.

**GLOMERATE.** Collected into close heads or parcels.

**GLOMERULI.** The same as *Soredia*.

**GLOMERULUS.** A cluster of capitules enclosed in a common involucre, as in *Echinops*.

**GLORIOSA.** The name of a group of remarkably handsome hothouse herbaceous-stemmed climbers, more correctly called *METHONICA*: which see. [T. M.]

**GLORY-TREE.** *Clerodendron*.

**GLOSSAPSIS** *tentaculata* is a tuberous-rooted orchid, peculiar to the island of Hong-kong and the adjacent mainland. According to Mr. Benthams, it has the habit

and characters of the small-flowered *Habenarias*, except that the terminal glands of the caudicles of the pollen-masses are received into distinct cells of the stigma. The root is an ovoid tuber; the stem, including the slender erect spike of small green flowers, eight to twelve inches high; the leaves three to four, oblong or lance-shaped, and one to three inches in length; the lip is deeply three-lobed, the lobes long and thread-like, somewhat resembling the antennæ of an insect. [A. A. B.]

**GLOSSOCOMIA.** A genus of bellworts distinguished by having the calyx five-lobed, reflexed; the corolla bell-shaped, five-lobed; the stigmas three, ovate; and the fruit three-celled. *G. ovata* is a hardy downy perennial, a native of Northern India, with ovate heart-shaped leaves and showy bell-like flowers. [G. D.]

**GLOSSODIA.** A small genus of Australian orchids, belonging to the tribe *Arctiæ*, and most nearly related to *Caladenia*, of which, according to Dr. Hooker, they may be considered a mere section, with no glands on the disk of the lip, and a solitary bifid long appendage at the base of that organ, somewhat resembling a serpent's tongue, whence the generic name. They have tuberous roots; a solitary lance-shaped or oblong leaf, about three inches long; and a slender, erect, nearly naked stem, six inches to a foot high, bearing at its apex from one to three extremely pretty blue flowers, sometimes beautifully speckled with white, and about an inch in diameter. The flowers are nearly regular, the lip undivided, the column winged, and the anthers terminal, with four powdery compressed pollen-masses. [A. A. B.]

**GLOSSOLOGY.** That part of Botany which teaches the meaning of technical terms.

**GLOSSONEMA.** A genus of *Asclepiadaceæ*, containing three species natives of Arabia and North-Eastern Africa. They are hoary perennial branching herbs, with opposite linear leaves, and small flowers on short interpetiolar peduncles. The calyx is five-parted; the corolla campanulate and five-cleft, with a tubercle on the inner surface of each lobe towards the apex; and the staminal crown is made up of five lobes alternating with those of the corolla, and having a dilated emarginate apex, with a contorted filament rising from the indentation. The stigma is slightly two-lobed; the follicles smooth, or covered with spines; and the seeds comose. [W. O.]

**GLOSSOPETALUM.** A small Mexican bush referred to the *Celastraceæ*, from the other genera in which, it is easily recognised by having ten stamens instead of five, and a simple instead of a compound pistil. *G. spinescens* is much branched, two to four feet high, having stiff rounded twigs, which end in spiny points, and are furnished with little alternate entire leaves, those on the flowering twigs being reduced to scale-like processes. The small

white flowers are axillary and stalked, and are succeeded by a little ovoid seed-vessel containing one seed, which is furnished with a minute aril.

[A. A. B.]

**GLOSSOSTEMON.** A genus of *Strochilaceae* nearly related to *Abronia*, and like it having pretty purple blossoms, but differing in the greater number of stamens and the form of the barren filaments. The stamens are thirty-five in number, disposed in five parcels, each parcel consisting of six anther-bearing stamens and a central barren one, which is much broader, longer, and tongue-like, whence the name of the genus. *G. Bruguieri*, the only species, is found in various parts of Persia. It is a low-growing plant, with a perennial rootstock, from which arise a few unbranched stems furnished with large soft leaves somewhat like those of a hollyhock. The stems and leaves, which are of a pale straw colour, are covered with starry hairs. Each stem terminates in a corymb of elegant dark purple flowers.

[A. A. B.]

**GLOSSOSTIGMA.** A genus of *Scrophulariaceae*, consisting of minute tufted moss-like plants, which are much resembling small

of the capsule bear the dissepiments in their centre, instead of being parallel to the dissepiment. There are two species, one a native of India, the other of New Zealand and Australia. The flowers in both are very minute.

**GLUTERON.** (Fr.) *Lappa communis*; also *Xanthium Strumarium*.

**GLOXINIA.** A genus of gesnerworts, distinguished by its corolla approaching to bell-shaped, with the border oblique, the upper lip shortest and two-lobed, the lower three-lobed with the middle lobe largest; and also by the summit of the style being rounded and hollowed. The name was given in honour of Gloxin, a botanical author of the last century. The species are natives of tropical America, and have opposite stalked leaves of rather thick texture, and axillary flowers, usually single or a few together, large, nodding, and of various colours (white violet red or greenish yellow), sometimes variegated with spots. The species are among the greatest ornaments of our hothouses, their richly-coloured leaves, and their nuple, graceful, and delicately-tinted flowers, having gained for them a prominent place among introduced plants. Here, as in many other instances, the process of hybridising has been resorted to with the best results; the older kinds with drooping flowers, have of late been giving place to forms with the corolla almost regular and nearly erect—the latter peculiarity having this recommendation, that the border and throat of the corolla, to which parts much of the beauty of the flower is owing, are presented to the eye. *Gloxinias* may be propagated by their leaves.

[G. D.]

**GLUMALES.** An alliance of Endogens,

comprising the grasses, sedges, and a few minor groups.

**GLUMA, GLUME.** The exterior series of the scales which constitute the flower of a grass.

**GLUMELLA.** That part of the flower of a grass now called the Palea or Pale. Also, in the language of Richard, one of the hypogynous scales in such a plant.

**GLUMELLULA.** The hypogynous scale in the flower of a grass.

**GLUTA.** Javanese trees with the appearance of the mango, and flowers in panicles resembling those of *Clematis Flammula*. The calyx is tubular and deciduous; petals four five or six, spreading, longer than the calyx, attached, as also are the stamens, to a stalk supporting the ovary; style lateral; fruit succulent, one-seeded. The genus belongs to the order *Anacardiaceae*.

[M. T. M.]

**GLUTINIUM.** The flesh of certain fungi.

**GLUTINOSE.** Covered with a sticky exudation.

**GLUTTIER.** (Fr.) *Sapium*. — DES OISELEURS. *Sapium aucuparium*.

**GLYCE.** A genus of *Cruciferae*, generally called *Kintia*, and now reunited to *Alysum* by many authors. It has the pouch nearly ovate, with flattish valves, the cells one or few-seeded, the funiculus of the seed adhering to the back of the septum, and the seeds wing-margined. The calyx is spreading, the petals entire, white or yellow, the hypogynous glands eight, and the filaments without basal appendages. *G. maritima*, the Sweet Alyssum of gardens, is found in some places in Britain, but only imperfectly naturalised where escaped from gardens.

[J. T. S.]

**GLYCERIA.** A genus of grasses belonging to the tribe *Festuceae*, distinguished principally from *Poa* by having the florets in more linear subcylindrical spikelets. The outer glumes and pales are membranaceous, with sharply prominent nerves, and a scarious margin. Steudel describes thirty-seven species, which are chiefly natives of the colder and more temperate parts of the world. The best known species is *G. fluitans*, or Manna-grass, which grows in most watery places in Britain. The long floating stems spread over pools of water and ditches, where cattle may frequently be seen wading to considerable depths to eat them. The seeds of some of the species are greedily fed on by ducks and other aquatic birds.

[D. M.]

**GLYCINE.** A small genus of *Leguminosae*, all, excepting one, being slender decumbent or twining herbs, with alternate stalked leaves made up of three to seven leaflets varying much in form, and bearing axillary racemes or fascicles of small yellow or violet pea-flowers. The genus belongs to the tribe *Phaseoleae*, and is most nearly allied to *Teramnus*, from which it dis-

tingulated by its pods being destitute of the hardened hooked style seen in the latter, and by the ten stamens, which are united into a tube, being all, instead of the alternate ones only, anther-bearing. The species are pretty equally distributed through tropical Asia, Africa, and Australia, where a few inhabit extratropical regions. The Sooja of the Japanese, *G. Soja*, the only erect species of the genus, a dwarf annual hairy plant, a good deal like the common dwarf kidney or French bean (*Phaseolus vulgaris*), has small violet or yellow flowers, borne in short axillary racemes, and succeeded by oblong two to five-seeded hairy pods. The seeds, like kidney beans in form but smaller, are called Miso by the Japanese, and are made into a sauce which they call Sooja or Soy. The manner of making it is said to be by boiling the beans with equal quantities of barley or wheat, and leaving it for three months to ferment, after which salt and water is added, and the liquid strained. The sauce is said to be used by them in many of their dishes, and they use the beans in soups. The Chinese cook the beans also in various ways, and the plant is cultivated for the sake of them in various parts of India and its Archipelago. Mr. Bentham groups the species in three sections, which some regard as genera: *Soja*, with flowers fasciated on the racemes, and falcate pods with depressions but not transverse lines between the seeds; *Johwin*, with flowers similarly arranged, and straight pods with transverse lines between the seeds; and *Leptocyanus*, with solitary flowers on the racemes, and straight pods. The *Glycine* or *Wistaria* of gardens is now referred to *Millettia*. [A. A. B.]

**GLYCOSMIS.** A name indicative of the sweetly-smelling flowers in the genus to which it refers, which consists of tropical Asiatic trees or shrubs, belonging to the *Aurantiaceae*, and closely allied to *Limonia*, but differing in the absence of spines, in the eight stamens being alternately long and short, in the short thick conical style, &c. *G. pentaphylla* is a common under-shrub in the uncultivated districts of Coromandel. *G. citrifolia* is remarkable for the delicious flavour of its fruits. [M. T. M.]

**GLYCYRRHIZA.** The best known plant of this genus is that which reputedly furnishes Spanish Liquorice, *G. glabra*—though possibly other species may be employed for the same purpose. *G. glabra* is an herbaceous perennial, with pinnate leaves and bluish flowers, and is cultivated in this country for the sake of its root, which contains a peculiar sugar-like substance, giving to the extract its flavour and slight demulcent property. To make the extract the root is sliced and boiled in water; after a time the liquor is strained and allowed to evaporate till it becomes of a proper consistence. Large quantities of this extract are imported from Spain, whence the term Spanish Liquorice; much is also imported from Italy, where it is prepared from the root of *G. echinata*. It is imported in rolls

five or six inches long, about the thickness of a man's thumb, and is packed in the leaves of the sweet bay. What is called refined liquorice is common liquorice dissolved in water, and again evaporated. It is said that both kinds are adulterated to a considerable extent, and that copper is often to be detected in them—probably from the extract having been made in an unclean copper vessel. Liquorice extract is demulcent in colds and coughs, but it is most extensively employed by the large porter brewers. The genus belongs to the *Leguminosae*, and is characterised by the presence of a tubular five-cleft two-lipped calyx; an ovate straight standard, a keel of two straight pointed petals; stamens in two parcels; style thread-like; pod ovate, compressed, one to four-seeded. [M. T. M.]

**GLYPHEA.** A genus of *Tiliaceae*, of which *G. graveolens*, the best known species, is a West African bush, having smooth, alternate, papery, three-ribbed, toothed leaves, varying from lance-shaped to oblong, and bearing yellow flowers in axillary umbels. They have a calyx of five narrow sepals, five petals; numerous stamens; and an ovary tipped with a simple style. The fruits are many-furrowed, spindle-shaped, three to five-celled, many-seeded, the seeds one above another, and separated by a thin cellular partition. [A. A. B.]

**GLYPHOSPERMUM.** A name applied to a genus of *Gentianaceae*, on account of the seeds, which are pitted. They are Peruvian shrubs, with small purple polygamous flowers, having a five-cleft tubular corolla, a one-celled ovary, no style, and a button-shaped two-lobed stigma. [M. T. M.]

**GLYPHOTENIUM.** A name proposed by J. Smith for *Goniopteris crispata*.

**GLYPTOSTROBUS,** or Embossed Cypress, is a genus of coniferous plants, allied to *Taxodium*. The name is derived from the Greek words 'glyptos,' carved or engraved, and 'strobos,' a cone, from the embossing on the scales. The flowers are monœclous. The cones grow at the end of lateral branches, and are ovate or oblong, consisting of several unequal leathery scales, which rise from the same point at the base; each scale covers two seeds, which are erect, ovate, and compressed. They are trees or shrubs, found in China, with straight or pendulous branches, and scattered, linear awl-shaped, three-angled leaves. *G. heterophyllus*, a small tree eight or ten feet high, is the Chinese Water Pine, planted along the margins of rice-fields near Canton, and found also in other parts of China. [J. H. B.]

**GMELINA.** A genus of *Verbenaceae*, consisting of a number of East Indian trees or shrubs, characterised by their cup-shaped minutely four to five-toothed calyx; tubular corollas, with the tube narrow below, somewhat bell-shaped above, and spreading and two-lipped at the border; and drupe-like two to four-celled fruits with one seed in each-cell. The leaves are simple,

entire, and generally oval and pointed; and the handsome yellow blossoms are disposed in raceme-like panicles, the branches of which are clothed with short yellow down. *G. arborea*, a large timber tree of the mountainous parts of India, affords a good wood useful for many purposes. According to Roxburgh, that of such trees as will square into logs from eighteen to twenty-four inches, bears much resemblance to teak, with the same colour, a closer grain, as light if not lighter, and easily worked. He found the wood to resist the effects of the sun and water better than teak, and remarks that the decks of pinnaces are made of this wood at Chittagong, &c., because it resists the weather better than any other, and does not shrink or warp. Of *G. Rheedii*, a Ceylon tree, producing large and numerous tawny-yellow flowers in the summer months, the bark and roots, as well as those of *G. asiatica*, are used medicinally by the Gingalese. [A. A. B.]

**GNAPHALIUM.** The Everlasting: a genus of plants belonging to the *Compositae*, distinguished from *Antennaria* by having the heads all alike and the receptacle naked, and from *Filago* by having the receptacle flat and not conical. The involucre or common calyx, in all the species, is of the peculiar character termed scarious or everlasting: hence the English name. Many of them, with white or straw-coloured flowers, are natives of the Cape of Good Hope. The foliage is usually thickly invested with white woolly down, and the flower-heads are remarkable for the permanence of their form and colour. *G. luteo-album* is the only British species which has any pretensions to beauty; it has only been found wild in one or two places in England, but is more frequent in Jersey. *G. uliginosum*, a minute tufted plant, with narrow cottony leaves, and numerous heads of small yellowish-brown flowers, is very common on damp heaths and in places where water has stood during winter. French, *Gnaphale*; German, *Ruhrpflanze*. [C. A. J.]

**GNAPHALODES.** Three little Australian weeds, belonging to the composite family, and in appearance much like our own cud-weeds (*Filago*), being clothed with cottony wool; they are, moreover, nearly allied to them, but differ in all the forets being perfect, instead of the outer ones being female and the inner perfect. The flower-heads have an involucre of numerous scales; and the achenes, seated on a cone-shaped naked receptacle, are smooth, and crowned with a pappus of five narrow and rigid filiform scales. [A. A. B.]

**GNAVELLE.** (Fr.) *Scleranthus*.

**GNAWED.** The same as EROSE.

**GNETACEÆ.** (*Joint Vire*.) A natural order of monochlamydeous dicotyledons, belonging to Lindley's class of Gymnogens. Small trees or creeping shrubs, not resinous, with jointed stems and branches, and opposite reticulated, sometimes scaly leaves. Flowers monoclous or dioclous, arranged in

catkins or heads, surrounded by opposite scales which unite more or less completely. The staminate flowers have a one-leaved perianth, and one-celled anthers, opening by pores; the pistillate ones either have no covering, or are enclosed by two scales. Ovules usually considered naked, one of their coats being protruded through the hole so as to form a long style-like process; seed with a succulent covering; embryo with a long twisted suspensor. Natives of temperate as well as warm regions in Europe, Asia, and South America. The seeds of some of them are eaten. There are two genera, *Ephedra* and *Gnetum*, and about thirty species. [J. H. B.]

**GNETUM.** A genus of plants typical of the order *Gnetaceæ*. The flowers are produced in cylindrical jointed catkins, the staminate ones having a membranaceous perianth, a single stamen, and an anther opening by a pore; and the pistillate ones being without any proper covering. The ovule is solitary and orthotropical; and the seed has an outer succulent coat. Trees or creeping shrubs found in tropical Asia and Guiana. They have jointed knotty branches, opposite, exstipulate, entire, smooth leaves, and axillary or terminal stalked catkins. There are some half-dozen species. The outer covering of the seeds of *G. urens* is lined with stinging hairs. The seeds of *G. Gnemon* and other species are roasted and eaten. [J. H. B.]

**GNIDIA.** A genus of *Thymelacæ*, bearing complete tetramerous flowers, whose calyx is coloured, funnel-shaped, with a regular four-divided limb; scales four to eight, inserted into the upper part of the calycine tube and projecting beyond it; anthers eight, in two rows, attached to the tube of the calyx; ovary sessile; style lateral, equalling the tube of the calyx; stigma capitate and papillose. The fruit is a nut, enclosed by the persistent calyx. Shrubs or undershrubs found in the southern and eastern tropical parts of Africa. They are heath-like plants, with slender branches, scattered or opposite leaves, terminal usually capitate flowers, which are of a white, yellow, reddish, or lilac colour, and are mostly pubescent externally. There are fifty known species. The bark of *G. daphnoides* supplies ropes in Madagascar. See *Lantophen*, [Surv.] [J. H. B.]

**GNOMONICAL.** Bent at right angles.

**GOATBUSH.** *Cassia Nicoloni*.

**GOATROOT.** *Ononis Natriz*.

**GOATWEED.** *Capraria biflora*.

**GOAT'S-BANE.** *Aconitum Tragacolonum*.

**GOAT'S-BEARD.** *Tragopogon*; also *Spiraea Aruncus*.

**GOAT'S-FOOT.** *Oxalis caprina*.

**GOAT'S-HORN.** *Astragalus Egiceras*.

**GOAT'S-THORN.** *Astragalus Tragacantha*, and *A. Poterium*.

**GOBBO.** *Adelmoschus esculentus*.

GOBE-MOUCHE. (Fr.) *Silene mucipula*; also *Dracunculus crinitus*, *Apocynum androsaemifolium*, &c.

GOBET. (Fr.) *Cerasus vulgaris*.

GOBLET-SHAPED. The same as Crateriform.

GOGO. The Japanese name of *Arctium Lappa*.

GOCKROO. *Ruellia longifolia*, an Indian drug.

GODET. (Fr.) *Narcissus Pseudo-Narcissus*.

GOETIA. A genus of ornamental annuals, belonging to the *Onagraceae*, and closely allied to Evening Primrose (*Oenothera*), from which they may be known by bearing flowers of a purple or pink hue, never yellow. The true Evening Primrose, as their name implies, do not open their flowers in the sunshine, but the *Goetias* are subject to no such rule. The majority of the species are natives of America, and are much grown in English gardens for the sake of their showy flowers. Some of them are remarkable for the brilliant colour of their anthers, and others for the deep purple spots on their petals. They are all very similar in habit, upright more or less branching herbs, with the broad four-petaled flowers in the upper leaf-axils. [G. A. J.]

GODOYA. A genus of tropical American trees, of doubtful position, but referred by Lindley to *Ochnaceae*. The leaves are shining, thick, marked with very numerous transverse striae or veins. The flowers are yellow, disposed in clusters, the calyx consisting of several series of overlapping coloured leaves; the five petals convolute; and the stamens numerous, the outermost of them sterile, free or united into five distinct bundles alternating with the petals, the inner ones free and fertile. The capsule woody, three to five-celled, bursting by five valves. *G. gemmiflora* is a stove plant of elegant appearance. [M. T. M.]

GOD'S FLOWER. *Helichrysum Stachas*.

GOD-TREE. *Eriodendron anfractuosum*.

GÖPPERITIA. A genus of Brazilian and West Indian trees, of the laurel family, having a six-parted wheel-shaped perianth, nine fertile stamens in three rows, the innermost row provided with glands, the anthers opening by two or four valves. Fruit placed within the hardened tube of the perianth. [M. T. M.]

GOGANE. (Fr.) *Fritillaria Meleagris*.

GOLDBACHIA. A genus of *Cruciferae*, consisting of annuals found in the Levant and in the Caspian Desert. They have alternate oblong leaves, and racemes of flowers, small, white or lilac, opposite the leaves. The pod is short, breaking transversely, when mature, into two one-seeded joints. [J. T. S.]

GOGO. *Entada Purpurea*.

GOKOKF. A collective Japanese name for bread-stuffs and pulse.

GOLD-CUPS. *Ranunculus bulbosus*, *acris*, &c.

GOLD-DUST. A popular name for *Alysum saxatile*.

GOLDE. *Calendula officinalis*.

GOLDEN-CHAIN. *Cytisus Laburnum*.

GOLDEN-CLUB. *Oroanthus*.

GOLDEN-CROWN. *Chrysosplenium*.

GOLDEN-FLOWER. *Chrysanthemum*.

GOLDEN-HAIR. *Chrysocoma Comaurea*.

GOLDEN-PERT. *Gratiola aurea*.

GOLDEN-ROD. The common name for *Solidago*; also *Leontice Chrysogonum*. —, RAYLESS. An American name for *Bignonia*. — TREE. *Loxa Yermamora*.

GOLD-FLOWER. *Helichrysum Stachas*.

GOLDFUSSIA. A considerable genus of *Acanthaceae*, containing twenty-four species, natives of India. They are shrubs with serrate penninerved leaves, having all the nerves directed upwards, but not reaching the apex. The flowers have two deciduous bracts, and are arranged in a head or spike, which after the fall of the bracts becomes very loose; there is an unequally five-parted calyx, a funnel-shaped corolla with an equally five-cleft limb, four didynamous included stamens with nodding anthers, and a subulate irritable stigma. [W. C.]

GOLDLOCKS, or GOLDBLOCKS. *Helichrysum Stachas*; also *Ranunculus auricomus*, *Hymenophyllum tumbridgense*, and a common name for *Chrysocoma*.

GOLDING. *Chrysanthemum segetum*.

GOLD-KNOBS, or GOLD-KNOPPES. *Ranunculus acris*, *bulbosus*, &c.

GOLD OF PLEASURE. *Camelina sativa*.

GOLD-SHRUB. *Panicum speciosum*.

GOLD-THREAD. *Coptis trifolia*.

GOL-KAERA. *Momordica mixta*.

GOMART. (Fr.) *Bursera*.

GOMBAUT, or GOMBO. *Abelmoschus esculentus*. Gombo is also used for the fibre-yielding *Hibiscus cannabinus*.

GOMMA DA BATATA. A purgative drug obtained from *Ipomoea operculata*.

GOMPHERIA. A genus of tropical ochnaceous trees or shrubs, most abundant in Brazil. They bear panicles of handsome yellow flowers, having the following structure: sepals five, coloured, imbricated; petals five, generally stalked; stamens ten, the anthers opening by pores; ovary five to six-lobed, placed on a thickened receptacle; stigma simple; drupes five, or fewer by abortion, placed on the enlarged receptacle. There are some eighty species, of which the majority are South American, a few African, and fewer still Asiatic. [M. T. M.]

**GOMPHOCAMPUS.** A rather considerable genus of *Asclepiadaceae*, containing fifty species of shrubs or herbs, natives of Southern and North-Eastern Africa and Arabia, and with one species common throughout the warmer regions of the world. They have opposite rarely whorled leaves, and generally showy flowers on many-flowered interpetiolar peduncles; the calyx five-parted, the corolla rotate or reflexed and five-parted; the staminal crown inserted on the top of the gynostegium, and consisting of five conduplicate leaflets, the pollen-masses attenuated upwards; and the smooth or echinate ventricose follicles containing many comose seeds. The leaves of *G. fruticosus*, the Arghel of Syria, are employed for adulterating senna: this plant is sometimes referred to *Solenostemma*. [W. C.]

**GOMPHOGYNE.** The name of a Himalayan climbing plant, belonging to the *Oncurbitaceae*. Its flowers are unisexual: the males with five sepals, five fringed petals, and five stamens which are united at the base; and the females with a one-celled ovary containing three ovules. The fruit is capsular. [M. T. M.]

**GOMPHOLOBIUM.** A genus of elegant leguminous undershrubs belonging to the tribe *Podalyriaceae*, in which the ten stamens are free. It comprises about thirty species, all of them found in South and West Australia. They are readily distinguished by their spherical or oblong many-seeded pods, and by their compound alternate leaves, made up of a varying number of leaflets, which are often heath-like. Many of them are cultivated in greenhouses, where they produce their blossoms in the spring and summer months. One of the most beautiful is *G. venustum*, a plant with slender flexuose branches furnished with smooth pinnate leaves of four to eight pairs of narrow linear leaflets, the stem terminating in a corymb of beautiful rose-purple pea-flowers. The largest-flowered species is *G. barbigerum*, so named because of the keel-petal being fringed; it is a smooth bush whose angular stems are furnished with trifoliate sessile leaves, of narrow flax-like leaflets, the pale yellow pea-flowers being solitary in the axils. Amongst a goodly proportion with heath-like leaves, *G. uncinatum* is noteworthy as being in South Australia very hurtful to sheep that may eat of it; the leaves are sessile and composed of three narrow leaflets hooked at the point; the flowers yellow, axillary, and solitary. [A. A. B.]

**GOMPHONEMA.** A genus of *Diatomeae*, distinguished by its forked permanent stems and wedge-shaped frustules, which are often contracted near the apex, and sometimes also towards the base when seen laterally. *G. Berkeleyi*, which is synonymous with the old *Meridion vernale*, occurs in every brook in spring, forming brown cushion-like gelatinous masses adhering to stones, leaves of aquatic plants, &c. *G. gemmatum* is less generally dif-

fused, but not uncommon, and is remarkable for its very large frustules, which form a magnificent microscopic object. The species were formerly confounded with *Vorticella*, a genus of undoubted animals, and well known to every student of freshwater *Algae* by the curious nodules of the stem. [M. J. B.]

**GOMPHOSIA.** A genus of cinchonaceous shrubs, natives of Peru and New Granada, having flowers whose calyx is provided with minute glands like those on the stipules. The corolla is salver-shaped, with a long tube, and a four to five-lobed limb; the stamens of unequal length, but all projecting beyond the corolla, the lobes of the anthers bent back, and connected by a very broad connective. The capsule is few-seeded, and bursts from above downwards into two valves. The seeds are winged. [M. T. M.]

**GOMPHOSTEMMA.** The generic name of plants belonging to the labiate order, having the corolla with its tube dilated upwards, and its border with two nearly equal lips; and the style with a bifid stigma, the two halves equal and awl-shaped. The species are herbs, natives of India, with simple, usually erect, rarely procumbent stems, the leaves large and shaggy with hairs. [G. D.]

**GOMPHRENA.** A genus of *Amaranthaceae*, in which the flowers are sometimes incomplete as regards stamens and pistils. There is a perianth of five leaves, very rarely five-cleft, five stamens united into a tube, the filaments dilated, with a trifid apex, the intermediate segment bearing a one-celled anther. The ovary is one-celled with a single ovule; the fruit one-seeded included within the perianth. They are undershrubs or herbs with opposite often semi-amplexicaul leaves, and flowers in lax spikes or panicles, or in globular heads. They abound in tropical America, and are rare in Asia and Australasia. There are ninety known species. [J. H. B.]

**GOMUTI, or GOMUTO.** An Eastern palm, *Saguerus saccharifer*, which yields a bristly fibre, called Gomuto or Goniuti fibre.

**GONAKIE.** An African name for *Acacia Adansoni*, which yields good building timber.

**GONANTHUS.** The name of an Indian herbaceous plant, of the *Arum* family, with a tuberous rootstock, peltate leaves, and a very long leathery spathe, rolled round at the base and prolonged into a long point at the other extremity. The spadix is short, bearing stamens above, ovaries in the middle, and rudimentary flowers at the lower part; anthers numerous, six-celled, the cells adhering in a whorl to the peltate thick connective, and opening by pores. Ovaries numerous, detached. [M. T. M.]

**GONGONHA.** *Ilex Gongonha*, the leaves of which, like those of *Mate*, *I. paraguayensis*, are used for making tea.

**GONGORA.** A singular genus of orchids found growing on tree-stems in tropical America. They have oblong, grooved, two-leaved pseudobulbs, the leaves broadly lance-shaped, plaited and a foot or more in length; and, growing from the base of the pseudobulb, drooping flower-racemes which are sometimes two feet long. The lateral sepals are free and spreading, the upper one remote and connate with the back of the lengthened, arched, hammer-headed column; the petals small and adnate to the middle of the column; while the curious clawed lip is continuous with the base of the column, and contracted in the middle, the lower portion being furnished on each side with a bristle-like horn, and the terminal part vertical and pointed, with the opposite faces folded together. The anther is two-celled, with two linear pollen-masses on the end of a narrow caudicle fixed at the base to a small gland. Upwards of a dozen species are known, *G. atropurpurea*, from Trinidad, has long pendent racemes of curiously formed purple flowers, reminding one of some insect. In *G. maculata*, from Demerara, they are yellow marked with blood-red spots. The structure of the flowers of these curious plants is very singular, and well repays examination. Those of *G. galeata*, better known in gardens under the name of *Acropera Lodigesi*, and especially those of a closely related plant called *Acropera luteola*, have been subjected to a close examination by Mr. Darwin, the result of which is that he believes some orchids to be unisexual, although both male and female organs are present in each flower. See Darwin, *On Orchid Fertilisation*, p. 31. [A. A. B.]

**GONGRONEMA.** A genus of *Asclepiadaceæ*, nearly allied to *Gymnema*, containing a few species of twining shrubs, natives of India. They have opposite coriaceous and glabrous leaves, and small flowers in large lax compound corymbs, except in one species in which they are arranged in a simple umbel. The calyx is five-parted, and the rotate corolla five-cleft, with the throat and tube naked; there is no staminal corona, but the gynostegium has small fleshy glands at its base. The follicles are smooth. [W. O.]

**GONGYLODES.** Having an irregular roundish figure.

**GONGYLOSPERMÆ.** A division of rose-spored *Algae*, containing those genera in which the spores are collected without order in a mucous or membranaceous mother cell. The nucleus is sometimes compound. The filamentous *Ceramiceæ*, and the solid *Rhodymeniaceæ* and *Cryptonemiaceæ*, belong to this division. [M. J. B.]

**GONGYLUS.** The spores of certain fungi. Also a round, hard, deciduous body connected with the reproduction of certain seaweeds.

**GONIDIA.** A name applied to the green spherical cells in the thallus of lichens which are the distinctive mark between

these plants and *Fungi*. They assume different types in different divisions. In most lichens they are of a pure green, and are developed from the tips of the constituent threads singly or in tufts; in *Collema* they are less highly coloured, and form moniliform threads resembling those of *Noctoe*; in *Paulia* they are large and gelatinous, increasing by cell-division as in some *Pulmonella*; while in *Ephra* they are quadripertite, and resemble *Hematococcus* in their development. The gonidia of Lichens have lately been observed to produce zoospores, an observation the more important on account of the analogy of the connecting cells of *Amabiema* with those of the gonidia of *Collema*. [M. J. B.]

**GONIOMA.** A genus of dogbanes, having the tube of the corolla angular at the upper part, the interior being hairy, and the border five-cleft; and two seed-vessels rough on the outside, the seeds having a long wing. *G. Kamaasi*, a native of the Cape, is a shrub with small yellow flowers. [G. D.]

**GONIOPHLEBIUM.** A genus of poly-podiaceous ferns, having the naked globose sort of *Polypodium*, and forming one of the genera of the polypodiaceous group with netted veins. The peculiar characteristic of *Goniophlebium* amongst these, is that the veins are forked or pinnate from a central costa, the lower anterior branches being usually free and fertile at the apex, and the rest angularly or arcuately anastomosing, and producing from their angles free excurrent veinlets, which

*Goniophlebium glaucophyllum.*

are often fertile, the marginal veinlets being free. There are often several series of anastomosing veinlets, but sometimes only one. The free (and in mature specimens usually fertile) veinlet produced within the basal areole distinguishes this group specially from its allies. There are a considerable number of species, found abundantly in South America and the West Indies, and in India and the Eastern and Pacific islands, more rarely in tropical Africa, the Mascaren islands, and Mada-

gascar. A few are simple-fronded species, with a creeping ivy-like habit, and contracted fertile fronds; but they have mostly stoutish slow-creeping rhizomes, and large pinnate or pinnatifid fronds, often of pendulous habit, and sometimes several feet in length, as in *G. subauriculatum*, a very handsome Javanese species, in which, as in a few other allied kinds, the sori are sunk in little hollows which form excrescence-like knobs on the upper surface. [T. M.]

**GONIOPTERIS.** A genus of polypodiaceous ferns, having round naked sori, and connitively anastomosing veins, in which latter peculiarity they differ from *Polypodium*. They have a short erect or decumbent caudex, and herbaceous or subcoriaceous pinnatifid, pinnate, or pinnatopinnatifid fronds, the latter having some resemblance in aspect to our common male fern. The species are not numerous, but widely dispersed, being found in the West Indies and South America, in tropical Africa and Madagascar, and in India, the Pacific islands, Australia, and New Zealand. [T. M.]

**GONIOSTEMMA.** A genus of *Asclepiadaceæ*, containing a single species, a native of India. It is a twining shrub, with opposite elliptical-oblong and glabrous leaves, and small flowers in lax many-flowered panicles like axillary cymes; they have rotate five cleft corollas, and the staminal crown is gamophyllous, tubular, five-angled and five-lobed, and adherent to the base of the gynostegium. This genus is separated from *Secamone* and *Toxocarpus*, its nearest allies, by the structure of the staminal crown, and by habit. [W. C.]

**GONOCALYX.** A very beautiful vacillaceous plant discovered by Schlim at an elevation of 7,000 feet in New Grenada, in the provinces of Pamplona and Ocuila. It forms a shrub of erect bushy habit, thickly clothed with small nearly orbicular leaves, and bearing fine bright red tubular flowers. The young leaves and shoots are of a purplish-rose colour. The only species has been called *G. pulcher*. [T. M.]

**GONOGONO.** *Myristica spuria*.

**GONOLOBUS.** A large genus of *Asclepiadaceæ*, natives of North America, consisting of twining herbaceous or shrubby plants, with opposite heart-shaped leaves, and greenish or dingy purple flowers in racemes or corymbs on interpetiolar peduncles. With a five-parted calyx, they have a rotate or reflexed and spreading corolla, the limb of which is five-parted, the staminal crown forming a small fleshy wavy-lobed ring in the throat. The folioles, which are turgid, more or less ribbed, and armed with soft warty processes, contain many canose seeds. Upwards of sixty species have been described. [W. C.]

**GONOPHORUM.** A short stalk which bears the stamens and carpels in such plants as anonads, &c.

**GONOSTEMON.** A section of *Stapelia*, characterised by having the outer of the two whorls of the staminal crown composed of five ligulate leaflets, and the interior of as many simple hooked spines. [W. C.]

**GONYANTHES.** A genus of *Burmanniaceæ*, consisting of two or three species from tropical Asia, differing from *Burmannia* chiefly in the capsule, which opens by transverse fissures opposite the cells. They are all slender leafless herbs, a few inches in height, with small terminal flowers, either solitary or few together in a little cyme.

**GONYSTYLUS** *Miquelianus* is the name given by Miquel to the tree that produces the fragrant wood called Kajin Garu by the Malays. It is very much like eaglewood, or *Aquilaria Agallochum*.

**GONZALEA.** A genus of South American shrubs belonging to the *Cinchonaceæ*. The tube of the calyx is somewhat globular, its limb four-parted; corolla funnel-shaped or salver-shaped, hairy externally, stamens four, included within the corolla; stigmas four; seeds minute. [M. T. M.]

**GOODENIACEÆ.** (*Goodenia*, *Scavola*, *Goodeniaceæ*, *Goodeniadæ*.) A natural order of calycifloral dicotyledons, belonging to Lindler's campanal alliance of epigynous Exogens. Herbs, rarely shrubs, not milky, with scattered exstipulate leaves and distinct flowers. Calyx usually superior, three to five-divided; corolla more or less superior, usually irregular, with a split tube and a five-parted lipped limb; aestivation conduplicate; stamens five separate; ovary one to two-celled; placentas free central; stigma surrounded by an indusium. Fruit capsular or drupaceous; seeds albuminous. Natives chiefly of Australia and the islands of the Southern Ocean. Some of the plants are used as esculent vegetables, and their pith is employed for economical purposes. *Scavola Taccada* furnishes the rice-paper of the Malay Archipelago; the leaves of the plant are eaten as a pot-herb, and its fruit is succulent. There are about two dozen genera, and nearly two hundred species. Examples: *Scavola*, *Goodenia*, *Velleia*, *Leschenaultia*. [J. H. B.]

**GOODENIA.** A genus of *Goodeniaceæ*, distinguished by having a superior calyx with a five-parted limb, the corolla generally two-lipped, with the tube cleft at the back; five stamens, with distinct anthers cohering before expansion; and a simple style, the stigma with a cup-shaped indusium. The capsule is two rarely four-celled. Herbaceous plants, or a few of them small shrubs, with alternate entire or toothed leaves, sometimes covered with white silky down, and axillary or terminal flowers usually yellow, rarely blue or purplish. Natives of Australia, Tasmania, and New Zealand; one species, *G. repens*, being also found in South America. [H. H.]

**GOODIA.** A genus of *Leguminosæ*, consisting of two nearly allied species, one, *G. tofolia*, widely distributed throughout S. and W.

Australia and Tasmania; the other, *G. pubescens*, confined to Tasmania and Victoria. Both are handsome much-branched bushes, with alternate trifoliate leaves like those of the birdfoot-trefoil—whence the name *lotifolia* applied to one of the species. The branches bear towards their apex racemes of golden yellow flowers, like those of a laburnum, but smaller. The chief features of the genus are the trifoliate leaves; two-lipped calyx, the lips not deeply divided; stamens all united into a sheath; and thin and flat veined pods. Its nearest ally is *Bossia*, from which the compound leaves distinguish it. *G. lotifolia* and *G. pubescens* are both in cultivation in greenhouses. The genus commemorates the name of Peter Good, a collector for Kew Gardens, who died in Australia. [A. A. B.]

**GOOD KING HARRY.** *Chenopodium* (or *Blitum*) *Bonus Henricus*.

**GOODYERA.** A genus of terrestrial orchids with small flowers like those of *Spiranthes*, but the spike is not spiral, and the lip does not embrace the column, has no callosities at the base, and is contracted at the top into a recurved point. It consists of very few species, all from the northern hemisphere, and mostly from high latitudes or mountain ranges. *G. repens*, generally found in moist woods, is widely spread over Northern Europe, Asia, and America, but in Britain only occurs in the highlands of Scotland. It has a creeping rootstock and an erect flowering stem of six inches to a foot, with a few ovate leaves near the base. The flowers are of a greenish white, in a slender one-sided terminal spike.

**GOOGUL.** *Balsamodendron Mukul*.

**GOOLS.** Various Marigolds, as *Calendula officinalis*, *Caltha palustris*, and *Chrysanthemum segetum*.

**GOOMALA.** *Balaia edulis*.

**GOOMPANY.** The wood of *Odina Woder*, used in India for railway sleepers.

**GOONCH.** A Hindoo name for the seeds of *Abrus precatorius*.

**GOONSOORA.** An Indian fibre-yielding *Hibiscus*.

**GOORA NUTS.** The seeds of *Cola acuminata*.

**GOORGOORA.** *Reptonia buxifolia*.

**GOOSE and GOSLINGS.** *Orchis Morio*.

**GOOSEBERRY.** *Ribes Cya crispum* (*Grossularia*). — **BARBADOS.** *Pereskia aculeata*. — **CAPE.** *Physalis pubescens*. — **COROMANDEL.** *Sperberia Corambola*. — **HILL.** of India. *Rhodomyrtus tomentosa*. — **TAHITI.** *Cleome disticha*.

**GOOSEFOOT.** A common name for *Chenopodium*; also *Aspalathus Chenopoda*.

**GOOSETONGUE.** *Achillea Ptarmica*.

**GOOSESHARE.** *Galium Aparine*.

**GOOWA.** The Betel nut, *Areca Catechu*.

**GORDONIA.** A genus of *Ternstroemia*, natives of North America and of the Alps of tropical and sub-tropical Asia, consisting of shrubs with alternate coriaceous entire leaves, and solitary one-flowered peduncles. The calyx is persistent, of five nearly equal concave sepals; the corolla of five petals alternate with the sepals, imbricate in aestivation; the stamens numerous, hypogynous. The fruit is a four to five-celled capsule, with two to four pendulous seeds in each cell. There are ten known species. [J. H. B.]

**GORSE.** The Common Furze, *Ulex europaeus*.

**GORTERIA.** A small genus of dwarf annual herbs of the composite family peculiar to South Africa, their stems and linear or oblong-lanceolate leaves more or less hispid, and the latter clothed underneath with a close-pressed white down; and the twigs terminated by solitary yellow flower-heads nearly an inch across, and somewhat like those of the common marigold. These have an involucre of many series of narrow scales with (eventually) hardened tips; when the flowers wither, these involucres contract at the top, so that the seeds cannot escape: the latter, therefore, when they germinate, push their stems upwards and their roots downwards through the spiny nut-like involucres, which remain attached at the collar of the root, and have the appearance of a spiny tuber of the size of a hazel-nut. The ray florets are strap-shaped neuter, those of the disk tubular and perfect; the achenes are villous at the summit only, and surmounted with a short crown-like pappus composed of a single series of scales, these characters of the fruit distinguishing the genus from *Gazania*, to which it is nearly allied. [A. A. B.]

**GORY-DEW.** *Palmella cruenta*.

**GOSSYPIANTHUS.** A genus of *Amaranthaceae*, containing perennial North American herbs with woolly procumbent stems, elongate spatulate root-leaves, those of the stem much smaller, opposite, nearly sessile, ovate, and entire, more or less densely covered with silky wool. The flowers are axillary, densely aggregated, covered with wool, and have a five-leaved perianth, five stamens with free filaments, and one-celled anthers without intermediate teeth. [J. T. B.]

**GOSSYPIUM.** This small genus of *Maliaceae* is one of the most important of the whole vegetable kingdom, for to it we are indebted for the valuable and well-known article Cotton, which occupies such a prominent place in the manufacturing industry of this and other countries, and which gives employment to so large a proportion of our mercantile marine. The number of species of *Gossypium* is extremely uncertain. Between twenty and thirty have been described and named by botanists, but the characters on which they are founded are so slight and variable,

that probably they may be reduced to five or six, three of which yield the Cotton of commerce. The genus is indigenous to both the Asiatic and American continents, but it has been so extensively spread by means of cultivation that it is now found throughout all parts of the world, within the limits of 36° north and south of the equator. All the species and varieties form herbaceous or shrubby perennial plants, varying in height according to the climate and soil in which they grow, some not exceeding two or three feet, while others reach a height of fifteen or twenty feet. Annual cotton plants are frequently spoken of, but, although generally treated as such, none of them are really annuals properly so called. Their leaves grow upon stalks placed alternately upon the branches, and are generally heart-shaped, and most commonly either three or five-lobed, with the lobes sharp or rounded; they generally have one or more glands upon the under side of the principal veins near the stalk. The flowers are usually large and showy, and grow singly upon stalks in the axils of the leaves. They have a cup-shaped shortly five-toothed calyx, surrounded by a larger outer calyx or involucre of three broad deeply cut segments, joined together and heart-shaped at the base; a corolla of five petals; many stamens united into a central column; and a three or five-celled ovary. The fruit is a three or five-celled capsule, which bursts open through the middle of each cell when ripe, exposing the numerous seeds covered with the beautiful cellular filaments known under the name of cotton. The seeds themselves contain a considerable quantity of bland oil, which has been brought greatly into use during the last few years; and the cake formed by pressing the decorticated seeds has proved a valuable food for cattle.

*G. barbadense* is the species cultivated

*Gossypium barbadense.*

in the United States, where two well-marked varieties are recognised. First, the Sea Island or long-staple cotton, which was introduced from the Bahamas in 1785,

and is only grown on the low islands and sea-coast of Georgia and South Carolina; it is the most valuable kind, having a fine, soft, silky staple from an inch and a half to an inch and three-quarters long, and is easily separated from the seed. Second, Upland, Georgian, Bowed, or short-staple cotton, which forms the bulk of American cotton, and is the produce of the upland or inland districts of the Southern States; the staple is only an inch or an inch and a quarter long, and it adheres firmly to the seed, which is also covered with short down. Egyptian cotton, and the kind called Bourbon, are likewise referable to this species.

*G. herbaceum* is the indigenous Indian species, and yields the bulk of the cotton of that country; it is also grown in the south of Europe and other countries bordering on the Mediterranean, Persia, &c. Its seeds are woolly and yield a very short-stapled cotton. *G. peruvianum* yields the cottons imported from Pernambuco, Bahia, and other parts of Brazil, from Peru, &c. It is sometimes called kidney cotton, on account of its seeds adhering firmly together in the form of a kidney.

The use of cotton dates from prehistoric ages, both in the Old World and the New. It is frequently mentioned in the *Institute of Manu*, a work written eight centuries before the Christian era. Upon the discovery of America it was found in common use among the inhabitants, and cotton cloth has since been found in the tombs of the Incas of Peru. From India the plant spread into Persia and Arabia; Pliny, early in the Christian era, mentions that it grew in 'Upper Egypt, on the side of Arabia,' where robes for the Egyptian priests were made of the cotton. It was brought to Spain by the Mahometan conquerors of that country, and from thence it spread through other parts of Southern Europe, but it has never formed an article of much importance in the agriculture of those countries. India supplied by far the largest part of the cotton fabrics used in Europe until the rise of the English manufactures in the latter half of last century. The introduction of this important manufacture into England took place about the close of the sixteenth century, when, in consequence of religious persecution, a number of Flemings fled to this country, and established it at Bolton and Manchester. But previously to the brilliant inventions of Hargreaves, Arkwright, Crompton, and others, it was merely a domestic manufacture, and the cotton was only used for the web of the cloth. At first our supply of raw cotton was obtained from Southern Europe and the Levant, and later from the West Indies and South America, and in smaller quantities from India and Bourbon. Towards the end of last century, however, the great and increasing demand caused the Americans to turn their attention to its production in the Southern States; and such has been their success that, till their fratricidal war broke out, they sup-

piled four-fifths of the enormous quantity annually consumed in this country. Some idea of the rapid increase of the English cotton manufactures may be gained from the fact that in the year 1751, previous to the introduction of spinning by machinery, our imports of raw cotton amounted to only 2,976,610 lbs., while in 1800 they had risen to 56,010,732 lbs.; and in 1860, the enormous quantity of 1,390,939,725 lbs. was imported, of which the United States supplied no less than 1,115,890,608 lbs.—a remarkable fact when we consider that the cotton plant is not indigenous to those States, and that its cultivation for exportation only commenced between seventy and eighty years ago.

The harvest in America commences in August and lasts till December. After being picked and dried, the cotton is separated from the seeds by means of machines called gins, and is then tightly compressed into bales averaging about 430 lbs. in weight. Two kinds of gins are used in America, the *saw-gin* and the *roller-gin*—the first, consisting of numerous circular saws revolving between iron grids, being used for the short-staple variety; and the latter, which is merely a pair of rollers, for the long-staple.

The value of English cotton manufactures in 1860 was estimated at 121,364,458*l.*, being the product of 33,000,000 spindles, giving employment, directly and indirectly, to one million men, women, and children, and requiring a capital of not less than 150,000,000*l.* sterling. [A. S.]

GO-TO-BED-AT-NOON. *Tragopogon pratensis*.

GOUANIA. A genus of *Rhamnaceæ*, consisting of large rambling climbing shrubs inhabiting the forests of tropical America and Asia, but principally the former. They have alternate leaves with veins running straight from the midrib to the margin; and some of their smaller branches are generally transformed into tendrils, which serve to support them. The flowers are usually produced in clusters along leafless branches, forming long slender spikes; the lower part or tube of their calyx adhering to the ovary, while the upper part is divided into five spreading segments alternating with five petals, each of which is partly rolled round a stamen, or has a stamen lying in a hollow formed by it. The fruit usually has three wings or sharp angles, but in some species it is nearly globular and without wings.

There are upwards of thirty species of this genus, the most interesting being *G. domingensis*, a common creeper in the West Indies and Brazil. In Jamaica it is called Chaw-stick, on account of its thin flexible stems being chewed as an agreeable stomachic; tooth-brushes are also made by cutting pieces of chaw-stick to a convenient length and fraying out the ends; and a tooth powder is prepared by pulverising the dried stems. It is said to possess febrifugal properties; and on account of its pleasant bitter taste is com-

monly used for flavouring different cooling beverages. [A. S.]

GOUDOTIA. A genus referred to *Juncaceæ*, founded on a curious little plant from the Andes, which has stems growing in dense tufts, with short distichous closely imbricated leaves, and stalked scarious flowers, diœcious by abortion. [J. T. S.]

GOUET. (Fr.) *Arum maculatum*. — A CAPUCHON. *Arisarum vulgare*. — CHEVELU, or GOBE-MOUCHE. *Dracunculus crinitus*. — EN CAPUCHON. *Arisæma ringens*. — SERPENTAIRE. *Dracunculus vulgaris*.

GOUL. *Adansonia digitata*.

GOURD. The common name for *Cucurbita*: the varieties of the common Gourd, *C. Pepo*, and of a few other species, are very numerous. — BITTER. *Citrullus Colocynthis*. — BOTTLE, CLUB, or TRUMPET. Different forms of *Lagenaria vulgaris*. — COLOCYNTH. *Citrullus Colocynthis*. — ETHIOPIAN SOUR. *Adansonia digitata*. — GOOSEBERRY. *Momordica echinata*. — ORANGE. *Cucurbita aurantia*. — SNAKE. *Trichosanthes*. — SPANISH. *Cucurbita maxima*. — SOUR. *Adansonia Gregorii*. — SQUASH. *Cucurbita Meloepo*. — WHITE, of India. *Bentlicasa cerifera*.

GOURDE. (Fr.) *Lagenaria vulgaris*.

GOURLIEA. A genus of *Leguminosæ* related to *Sophora*, but the pods, instead of being long and constricted between the seeds, are elliptical with a somewhat fleshy rind, of the size and form of a plum-stone when mature, and usually perfecting but one seed. There is but one species known, *G. chilensis*, native of extratropical S. America. It is a bush or small tree, with pale smooth bark, and short spine-like lateral branches, from which arise racemes or fascicles of small yellow pea-flowers. At the time of flowering, the hoary leaves, which consist of about four pairs of oblong leaflets and an odd one, are not fully developed. Chanar or Chanal is the name given to the bushes in Chili and Buenos Ayres; and, according to Tweedie, the pulp of the fruit is used in flavouring sweet wines in the latter place, and at Entre Rios. The name of Mr. Robert Gourlie, who gathered plants at Mendoza and died there, is perpetuated in the genus. [A. A. B.]

GOUTTE DE LIN. (Fr.) *Cuscuta europæa*. — DE SANG. *Adonis autumnalis*.

GOUTWEED, or GOUTWORT. *Egopodium Podagraria*.

GOUTY-STEMMED TREE. An Australian name for *Delabachea*.

GOUYAVIER, or GOYAVIER. (Fr.) *Psidium*.

GOVENIA. A genus of terrestrial orchids peculiar to the moist woods of tropical America. The leaves are radical, broadly lance-shaped or oblong, plaited, and from one to two feet in length. The

erect flower-scape also is radical, and terminates in a spike or raceme of medium-sized flowers, each supported by a narrow bract; they are usually white or cream-coloured, but in some yellow, with or without blood-red spots. The sepals and petals are free and of nearly equal length; the lip much shorter, without spur, entire, and joined to the base of the column; and the anther contains four solid pollen-masses fixed to a short caudicle with a small triangular gland. There are sixteen species known, seven of which have been cultivated, but none are remarkable for their beauty. The genus is named after J. R. Gowan, Esq. [A. A. B.]

GOWAN. In Scotland, the Daley, *Bellis perennis*; but appertaining rather to *Caltha*, *Calendula*, and *Chrysanthemum*. from 'gowian,' a corruption of 'golden' see GOOLA, and GOLDS.

GOZELL. The Gooseberry, *Ribes uva-crispa*.

GRABOWSKIA. This ill-sounding name is applied, in honour of a Silesian botanist, to a curious Brazilian shrub which has been referred to *Solanaceae*, but seems more closely allied to *Ehretiaceae*. *G. boerhaaviifolia* is much-branched, with axillary spines, and solitary flowers opposite the leaves or grouped in panicles at the end of the branches. Its flowers have five stamens projecting from the tubular corolla, their filaments hairy in the middle; and a four-celled ovary. The fruit is succulent, enclosed within the calyx, having two woody stones, each divided into two compartments containing a single seed. [M. T. M.]

GRACILARIA. A genus of rose-spored *Algae* belonging to the natural order *Sphaerococcoidae*, amongst which it is distinguished by its cylindrical compressed or flat frond with oblong cruciate tetraspores dispersed among the superficial cells of the branches and branchlets. It is the same with *Plocaria*, and therefore furnishes the Corsican and Ceylon moss. [M. J. B.]

GRACILIS. Slender; applied to parts which are long and narrow.

GRÆLLIA. A genus of *Cruciferae* found in Persia, and represented by *G. saxifragifolia*, a perennial herb, with a habit like that of *Saxifraga granulata*. The leaf-stalks remain attached to the short root-stock after the smooth rounded notched blades wither; the flower-stalk bears a number of white racemed flowers not unlike those of the cuckoo-flower; while the fruits are small oblong much-compressed siliques, ripening but a single seed. [A. A. B.]

GRAHAMIA. A genus of *Portulacaceae*, consisting of a small Chilean shrubby plant, with alternate fleshy oblong terete leaves, and solitary flowers at the extremity of the branches, the calyx having eight or nine imbricated bracts, the white petals five in number, and the stamens

numerous, with the filaments united at the base. [J. T. S.]

GRAINS OF PARADISE. The seeds of *Amomum Grana Paradisi*; also called Gunea Grains.

GRAINES D'AMBRETTE. (Fr.) *Abelmoschus moschatus*. — DAVIGNON. *Rhamnus infectorius, saratilis*, &c. — DE CANARY. *Phalaris canariensis*. — DES MOLUQUES. *Croton Tiglium*. — MUS-QUEES. *Abelmoschus moschatus*. — D'ORSEAU. *Phalaris canariensis*. — DE FERRO-QUET. *Carthamus tinctorius*. — DE TILLY. *Croton Tiglium*.

GRAM. The Chick Pea, *Cicer arctinum*. — BLACK. *Phaseolus Mungo melanospermus*. — GREEN. *Phaseolus Mungo chlorospermus*, and *P. radiatus*. — HORSE. *Dolichos uniflorus*. — TURKISH. *Phaseolus acanthifolius*. — RED. *Dolichos Catjang*. — WHITE. *Sofa hispida*.

GRAMEN FLEURI. (Fr.) *Stellaria Holstea*. — TREMBLANT. *Brisa media*.

GRAMIGNA. The underground stems of *Triticum repens*, used in Italy as food for horses.

GRAMINACEÆ. (*Gramineæ, Grasses*.) A natural order of glumiferous monocotyledons belonging to Lindley's glumal alliance of Endogens. Herbaceous plants with round usually hollow jointed stems; narrow alternate leaves, having a split sheath and often a ligule at its summit; and flowers arranged in spikes or panicles, perfect or imperfect. The flowers are composed of a series of leaves or bracts—the outer, called glumes, alternate, often unequal, usually two, sometimes one, rarely none; the rest, called pales or glumellets, usually two, alternate, the lower or outer one being simple, the upper or inner having two dorsal or lateral ribs, and supposed to be formed of two pales united; sometimes one or both are wanting. The glumes enclose one or more flowers, and among the flowers there are often abortive florets. Stamens hypogynous, one to six, usually three; anthers versatile. Ovary superior, one-celled, with two (rarely one or none) scales called lodicules; ovule one; styles two or three, rarely united; stigmas often feathery. Fruit a caryopsis; embryo lenticular, lying on one side at the base of farinaceous albumen. Grasses are widely distributed over the world, forming about one twenty-second of all known plants, according to Schouw. They are social plants, forming herbage in temperate climates, and becoming arborescent in tropical countries. The order is a very important one, as supplying food for man and animals. The various cultivated grains and the pasture grasses belong to it. It is said that darnel grass (*Lolium temulentum*) has poisonous qualities, and some think that it is the tares of Scripture. Several species of *Andropogon* yield fragrant oils, such as kum-kus, roussea oil, and citronelle. The bamboo (*Bambusa arundinacea*) is one of the most useful grasses in warm

countries; the sugar-cane (*Saccharum officinarum*) is another valuable grass from a commercial point of view. Among the cereal grasses cultivated for food may be enumerated:—wheat, barley, oats, rye, rice, Indian corn, millets, Guinea corn, and swamp rice. The grains of *Coix Lachryma* are used as beads under the name of Job's tears. The tussac grass of the Falkland Islands is the *Dactylis cespitosa*. Some grasses are useful in binding the loose sand of the sea-shore. There are about 300 genera of grasses and 4,000 species. Examples: *Oryza*, *Zea*, *Phleum*, *Panicum*, *Anthoxanthum*, *Poa*, *Dactylis*, *Festuca*, *Bromus*, *Bambusa*, *Lolium*, *Triticum*, *Hordeum*, *Saccharum*. [J. H. B.]

**GRAMMADENIA.** A small genus of *Myrsinaceae*, found in the West Indies and the adjoining mainland, related to *Myrsine*, but having the flowers in racemes instead of fascicles; and to *Cybianthus*, but having a five to six-parted instead of four-parted calyx and corolla. Their stems are abundantly furnished with sessile, lance-shaped, entire leaves, marked with curious linear glands, thus suggesting the name of the genus. The very minute flowers are succeeded by a globose ovary, which becomes when ripe a round berry the size of a small pea, with few seeds. [A. A. B.]

**GRAMMANTHES.** Succulent herbaceous plants, natives of the Cape of Good Hope, forming a genus of *Crassulaceae*, nearly allied to *Crassula*, but distinguished from it by the corolla, which is tubular, with a limb divided into five or six oval lobes, and by the absence of scales at the base of the ovary. They are pretty little plants as seen during sunshine. [M. T. M.]

**GRAMMATOCARPUS.** A genus of *Lonicaceae* found in Chili, and nearly allied to *Lonicera*, differing chiefly in its slender twisted capsular fruits, which are one to two inches long, and not much thicker than their stalks. The Chilean and only species, *G. volubilis*, is a slender twining annual herb, with opposite twice pinnatifid leaves, and stalked yellow cup-shaped flowers, solitary in the axils of the leaves, and nearly an inch across; they have a calyx border of five linear segments; ten petals, five large and somewhat spurred at the base, and five smaller three-awned at the apex; and numerous stamens, the fertile ones in five bundles. [A. A. B.]

**GRAMMATOPHYLLUM.** The few species which make up this genus of orchids are amongst the most choice in cultivation. *G. speciosum* has been called the Queen of Orchidaceous plants. This superb species, a native of Java and the adjacent islands, has stout stems from six to ten feet long, bearing a number of strap-shaped leaves one to two feet in length, arranged in a two-ranked manner. The flower-scape arises from the base of the stem, and is sometimes six feet in length, the flowers numerous but distant on the panicle, each borne on a stalk (ovary) about six inches long, this being also the diameter of the fully

expanded flowers, which are of a bright yellow colour, spotted and blotched with deep purple; the lip is trilobed and comparatively small. From Manilla we have *G. multiflorum*, a plant with pseudobulbs instead of lengthened stems, producing from its apex three or four long strap-shaped leaves, and from its base a raceme nearly two feet long of yellow flowers beautifully painted over with blood-red stains of grotesque form. *G. Ellisii*, another pseudobulbous species, was introduced from Madagascar, and has the sepals and petals yellow and beautifully barred transversely with dark blue, while the petals and lip are of a pale pink colour. This plant is considered by Reichenbach to form a distinct genus, to which he gives the name *Grammania*. The genus is nearly related to *Cymbidium*—the principal difference being, according to Dr. Lindley, that in the latter the gland of the pollen-masses is triangular, while in this it is crescent-shaped, with one pollen-mass at each extremity of the crescent. There is also a shallow sac at the base of the column and lip, not noted in *Cymbidium*. [A. A. B.]

**GRAMMATOTHECA.** A genus of slender branching herbs, natives of the Cape of Good Hope, and belonging to the *Lobeliaceae*. They are distinguished mainly by their corolla, which is tubular below, with a five-parted limb in two divisions, the lower lip consisting of three pendent segments, larger than the two constituting the upper lip; the style is concealed within the corolla, and bears a two-lobed stigma whose lobes are widely separate one from the other. The genus is closely related to *Clintonia*. [M. T. M.]

**GRAMMITIS.** A genus of polypodiaceous ferns, producing oblique naked oblong or elliptic sori, and having free simple or forked veins. The group is often restricted to certain small simple-fronded plants, of which *G. Billardieri* may be taken as the type; but to these are sometimes added a few larger compound-fronded species, more closely resembling *Gymnogramma* in habit, but having simple oblong instead of forked sori. [T. M.]

**GRAMMICUS.** When the spots upon a surface assume the form and appearance of letters.

**GRAMON DE MONTAGNE.** (Fr.) *Smilax aspera*.

**GRANA MOLUCCANA.** The seeds of *Croton Tiglium* and *Pavona*. — **PARADISI.** The seeds of *Amomum Gramum Paradisi*. — **SAGU.** The granulated Sago of commerce. — **TETRASTICHA.** The spores of certain fungals. — **TIGLIA** or **TILLA.** The seeds of *Croton Tiglium*.

**GRANADILLA.** *Passiflora quadrangularis*, *maliformis*, *lucrifolia*, *incarnata*, *edulis*, &c., which bear edible fruits.

**GRAND BAUME.** (Fr.) *Pyrethrum Tanacetum*. — **GENTIANE.** *Gentiana lutea*. — **MILLET.** *Sorghum vulgare*. — **MO-**

NARQUE. *Narcissus concolor*. — ORCHIS MILITAIRE. *Orchis fusca*. — PIN. *Pinus Pinaster*. — PLANTAIN. *Plantago major*. — RAIPORT. *Cochlearia Armoracia*. — SCEAU DE SALOMON. *Convolvulus multiflorus*. — TRÈFLE ROUGE. *Trifolium pratense*. — VALÉRIANE. *Valeriana Phil.*

GRANDE CAPUCINE. (Fr.) *Tropaeolum majus*. — CIGUË. *Conium maculatum*. — CONSOÛDE. *Synphytum officinale*. — DOUVE. *Ranunculus Lingua*. — ÉCLAIRE. *Chelidonium majus*. — ÉPIAIRE. *Stachys sylvatica*. — ÉSULE. *Euphorbia Lathyris*. — FOUGÈRE. *Pteris aquilina*. — GESSE. *Lathyrus latifolius*. — LUNAIRE. *Lunaria biennis*. — MAÛVE. *Malva sylvestris*. — ORTIE. *Urtica dioica*. — OSEILLE. *Rumex Acetosa*. — PATIENCE DES EAUX. *Rumex Hydrolapathum*. — PERVENCHE. *Vincetoxicum major*. — RENOUÉE. *Polygonum orientale*. — SAUGUE. *Salvia officinalis*. — VRILLÉE BÂTARDE. *Polygonum dumetorum*.

GRANGEA. A few small prostrate or erect weeds of the chamomile group of the composite family, most nearly related to *Cotula*, differing chiefly in the broadly three-toothed ray florets, and in the presence of a small cup-shaped fringed pappus. The species are widely diffused over the tropics of both hemispheres; and have pinnatifid leaves, and solitary terminal yellow flower-heads, much like those of a chamomile divested of its white ray florets; all the florets are tubular, the outer bearing pistil only, the inner perfect. *G. maderaspatana*, a very common weed all over India, occurs in Brazil, growing abundantly in sandy plains, and is used, according to

tubular and perfect, placed upon a pitted receptacle, with membranous scales between the pits; the branches of the style are elongated and cylindrical. The fruits are somewhat cylindrical, ribbed, crowned by a pappus, of which the outer row consists of a few narrow scales, the inner of hairy bristles. [M. T. M.]

GRANULA. Large spores contained in the centre of many algae, as *Gloionema*. Among fungals it sometimes expresses a spore-case.

GRANULAR, GRANULATE. Divided into little knobs or knots, as the roots of *Saxifraga granulata*.

GRANULES. Any small particles; grains; the hollow shells which constitute pollen.

GRAPE. The well-known fruit of the vine, *Vitis vinifera*. — BEARS. *Vaccinium Arctostaphylos* and *Arctostaphylos Uva ursi*. — CHICKEN. *Vitis cordifolia*. — CORINTH. The fruits of the Black Corinth variety of *Vitis vinifera*, which when dried form the currants or corinths of the shops. — FOX. *Vitis vulpina* and *Vitis Labrusca*. — FROST. *Vitis cordifolia*. — SEA. *Ephedra distachya*; also *Sargassum bacciferum*. — SEASIDE. *Coccoloba*, especially *C. uvifera*. — WILD, of Peru. *Chondrodendrum convolvulaceum*. — WINTER. *Vitis cordifolia*.

GRAPE FLOWER. *Muscari racemosum*.

GRAPHIDEI. A natural order of lichens, distinguished by the disk of the fruit being linear and either simple or branched. There is generally a distinct receptacle, though this is sometimes wanting. It is exactly analogous to *Hysterium* amongst Fungi. Many fine species occur in tropical

name of Marcellia.

[A. A. B.]

GRANGERIA. A genus of *Chrysobalanaceae*. *G. borbonica*, the only species, is a common bush or small tree of the Mauritius, where it is known as Arbre de Buis (box tree). It has glossy green coriaceous leaves, in form like those of the common box but somewhat larger; and the small white flowers are disposed in short racemes, and have a five-parted calyx, five rounded petals, fifteen stamens, and a style arising from the base of a woolly ovary which, when ripe, becomes a three-sided pyriform drupe, with a single seed. The genus is nearly related to the American *Hirtella*, but differs in the stamens being regularly disposed, and not all arising from one side of the flower. [A. A. B.]

GRANITICUS. Growing in granitic soil.

GRANTIA. A genus of Persian herbaceous succulent-leaved composite plants. The involucre consists of two rows of somewhat leafy bracts; the outer florets are strap-shaped and neuter, the inner ones

forests. In *Sclerophyton* the fruit is collected in linear elevations of the crust, so that it is parallel with *Trypethelium* amongst *Verrucariæ*. Though *Opogon* is so common in the northern hemisphere, it does not occur at all in New Zealand. In *Arthronia*, which is one of the lowest genera of lichens, the receptacle vanishes altogether. [M. J. B.]

GRAPPLE PLANT. The colonial (Cape) name of *Uncaria procumbens*.

GRAPTOPHYLLUM. A genus of *Acanthaceae*, consisting of *G. hortense*, a native of India, but which having escaped from gardens has been diffused over the tropical regions of both the Old and New worlds. It is a shrub with oblong or ovate variegated leaves, and flowers in terminal racemes; they have an equally five-parted calyx, a pliant corolla with the upper lip arched and the lower tri-lobed, and two stamens with sagittate anthers. The capsule is rostrate. [W. C.]

GRASS. A general name for all grami-

naceous plants. —, **ARROW.** *Triglochin*.  
 —, **ARTIFICIAL.** A name given by agriculturists to various fodder plants, as clover, lucerne, sainfoin, &c. —, **AWNED HAIR.** *Muhlenbergia capillaris*. —, **BAL-LOOK.** *Orchis*. —, **BARLEY.** *Hordeum*. —, **BARNYARD.** *Panicum Orus galli*. —, **BASTARD KNOT.** *Corrigiola littoralis*. —, **BASTARD MILLET.** *Paspalum*. —, **BEAK.** *Fucca flamentosa*. —, **BEARD.** *Andropogon*. —, **BENT.** *Agrostis*; also applied to any wiry-stemmed grass growing on a bent or common. —, **BERMUDA.** *Cynodon*. —, **BLACK.** *Alopecurus agrestis*. —, **BLACK OAT.** *Stipa avenacea*. —, **BLUE.** *Poa compressa*. —, **BLUE-EYED.** An American name for *Stagyrinchium*. —, **BOTTLE.** *Setaria glauca*. —, **BOTTLE-BRUSH.** An American name for *Elymus hystrix*. —, **BRISTLE-TAILED.** *Cheturus*. —, **BRISTLY FOXTAIL.** *Setaria*. —, **BROME.** *Bromus*. —, **HURDOCK.** *Lappago racemosus*. —, **BURL.** *Cenchrus*. —, **CAPONSTAIL.** *Festuca Myurus*. —, **CANARY.** *Phalaris canariensis*, the grain of which is the canary seed of the shops. —, **CARNATION.** *Carex glauca*, and others. —, **CATSTAIL.** *Phileum*. —, **CHINA.** The fibre of the Rheen, *Bihmeria nivea*. —, **CLAYER.** An old name for Clover, *Trifolium pratense*. —, **COCK'S COMB.** *Cynosurus echinatus*. —, **COCK'S FOOT.** *Dactylis glomerata*. —, **COMB-FINGER.** *Dactyloctenium*. —, **COLD.** *Spartina stricta*. —, **COTTON.** *Eriophorum*. —, **COUCH.** *Triticum (Agropyrum) repens*. —, **COW.** *Trifolium pratense*; also *Polygonum aviculare*. —, **CRAB.** *Digitaria sanguinalis*; also an American name for *Eleusine*; also *Salticornia herbacea*. —, **CRESTED HAIR.** *Kaloria cristata*. —, **CUCKOO.** *Luzula campestris*. —, **DARNEL.** *Lolium*; also especially *Lolium temulentum*. —, **DEER.** *Rhexia*. —, **DEW.** *Dactylis glomerata*. —, **DITCH.** An American name for *Ruppia*. —, **DOG.** *Triticum caninum*. —, **DOG'S-TAIL.** *Cynosurus*. —, **DOG'S TOOTH.** *Triticum caninum*. —, **DOOB.** *Cynodon Dactylon*. —, **DROP-SEED.** An American name for *Sporobolus* and *Muhlenbergia*. —, **EEL.** An American name for *Zostera* and *Vallisneria*. —, **ELEPHANT'S.** *Typha elephantina*. —, **FALSE RED-TOP.** *Poa serotina*. —, **FEATHER.** *Stipa pennata*. —, **FES-CUE.** *Festuca*. —, **FINGER.** *Digitaria*. —, **FLORIN.** *Agrostis vulgaris*; now more commonly applied to *A. alba* and *stolonifera*. —, **FIVE-LEAVED.** *Potentilla reptans*. —, **FLEA.** *Carex pulicaris*. —, **FLOTE, or FLOAT.** *Glyceria fluitans*. —, **FODDER.** *Chilochoa*. —, **FOUR-LEAVED.** *Paris quadrifolia*. —, **FOXTAIL.** *Alopecurus*. —, **FRENCH.** *Onobrychis sativa*. —, **FRENCH SPARROW.** *Ornithogalum pyrenaicum*. —, **FROG.** *Salicornia herbacea*. —, **GALLOW.** *Connaris sativa*. —, **GAMA.** *Tripsacum dactyloides*, an esteemed fodder grass in North America and Mexico. —, **GHOHONA.** A reputedly poisonous Indian grass, supposed to be *Paspalum scrobiculatum*. —, **GINGER.** *Andropogon Nardus*. —, **GOAT'S BEARD.** *Agropogon*. —, **GOOSE.** *Galtum Aparine*;

also *Potentilla anserina*; also an American name for *Polygonum aviculare*. —, **GREAT GOOSE.** *Asperugo procumbens*. —, **GREEN.** *Chloris*. —, **GRIP.** *Galtum Aparina*. —, **GUINEA.** *Panicum jumentorum*, also known as *P. maximum*. —, **HAIR.** *Aira*; also *Trichochloa*; also an American name for *Agrostis scabra*. —, **HARD.** *Sclerophon*; also *Egilops*; also *Dactylis glomerata*. —, **HARESTAIL.** *Lagurus*. —, **HAS-SOCK.** *Aira caespitosa*. —, **HEATH.** *Triodia decumbens*. —, **HEDGEHOG.** *Echinochloa*; also applied in America to *Cenchrus*. —, **HERD.** *Agrostis dispar*. —, **HERD'S, of New England.** *Phleum pratense*. —, **HERD'S, of Pennsylvania.** *Agrostis vulgaris*. —, **HOLY.** *Hierochloa borealis*. —, **HORN.** *Cervuchloa*. —, **HORN OF PLENTY.** *Cornucopia cucullatum*. —, **INDIAN.** An American name for *Sorghum nutans*. —, **INDIAN DOOB.** *Cynodon Dactylon*. —, **KANGAROO.** *Anthistiria australis*. —, **KNOT.** *Triticum repens*; also *Illecebrum* and *Polygonum aviculare*. —, **KNOT, of Shakspeare.** *Agrostis stolonifera*. —, **LEMON.** *Andropogon Schenanthus*. —, **LOB, or LOP.** *Bromus mollis*. —, **LONG.** *Macrochloa*. —, **LOVE.** *Eragrostis*. —, **LYME.** *Elymus*. —, **MAIDENHAIR.** *Briza media*. —, **MANNA.** *Glyceria fluitans*. —, **MARL.** *Trifolium pratense*, or, according to some authorities, *T. medium*. —, **MARRAM.** *Elymus arenarius*; also *Ammophila arenaria*. —, **MARSH.** An American name for *Spartina*. —, **MARSH HEDGEHOG.** *Carex flava*. —, **MAT.** *Nardus stricta*; also *Ammophila arenaria*. —, **MEADOW.** *Poa*. —, **MELIC.** *Melica*. —, **MILLEET.** *Milium*; also *Sorghum vulgare*, *Panicum miliaceum*, *Setaria italica*, &c. —, **MONKEY.** A commercial name for the whalchone-like fibre of *Attalea funifera*. —, **MOOR.** *Setaria cernua*. —, **MOUNTAIN, of Jamaica.** *Andropogon bicornis*. —, **MOUSE-EAR.** *Scorpioides*. —, **MOUSETAIL.** *Myosotis palustris*. —, **MOUSETAIL.** *Festuca Myurus*; also *Alopecurus agrestis*. —, **MYRTLE.** *Acorus Calamus*. —, **NAKED-BEARD.** *Gymnopogon*. —, **NIT.** *Gastrium*. —, **NUT.** *Cyperus Hydras*. —, **OAT.** *Arrhenatherum avenaceum*; also various species of *Avena*; also *Bromus mollis*. —, **OF PARNASSUS.** *Parnassia*. —, **ONE-GLUMED.** *Monachne*. —, **ORANGE.** *Hypericum Sarcotra*. —, **ORCHARD.** *Dactylis glomerata*. —, **PAMPAS.** *Gyntherium argenteum*. —, **PANIC.** *Panicum*; also *Ehrharta panicata*. —, **PARA.** A commercial name of the Plassiba fibre of *Attalea funifera*. —, **PENNY.** *Rhynchos Crista galli*. —, **PEPPER.** *Ptilularia globulifera*; also an American name for *Leptidium*. —, **PIGEON'S.** *Verbena officinalis*. —, **POVERTY.** *Aristida dichotoma*. —, **PRICKLY.** *Echinochloa*. —, **PUDDING.** *Mentha Pulegium*. —, **QUAKE, or QUAKING.** *Briza*. —, **QUICK, or QUITCH.** *Triticum repens*. —, **RATTLESNAKE.** *Glyceria canadensis*. —, **RAY.** *Lolium perenne*. —, **RED-TOP.** *Urtica cupress*. —, **REED.** *Arundo*; also *Onoclagrostis*, and *Phalaris*. —, **REED BENT.** *Calamagrostis*. —, **RIB.** *Plantago lanceolata*. —,

RTE. *Hordeum pratense*; also *Lolium perenne*. —, RIBBON. *Digraphis arundinacea variegata*. —, RICE CUT. An American name for *Leersia oryzoides*. —, ROPE. Restio. —, ROT. *Pinguicula vulgaris*. —, ROUGH. *Dactylis glomerata*. —, RUSH. An American name for *Vilfa*. —, RUSH SALT. *Spartina juncea*. —, RYE. *Hordeum pratense* and *murinum*; also *Secale* and *Lolium*. —, SAND. *Urtica purpurea*. —, SCORPION. *Myosotis*. —, SCOTCH. of Jamaica. *Panicum molle*. —, SCURVY. *Cochlearia officinalis*. —, SEA. *Ruppia maritima*. —, SEA HARD. *Ophirurus*. —, SEA LYME. *Elymus*. —, SEA MAT. *Ammophila arenaria*. —, SEA SP R. *Glyceria distans*. —, SENECA. *Hierochloa borealis*. —, SESAME. *Tripsacum*. —, SHAVE. *Equisetum hyemale*. —, SHELLY. *Triticum repens*. —, SHERE. Carex. —, SHORE. *Littorella lacustris*. —, SHRUBBY. *Thamnochortus*. —, SILK. *Eriocoma cuspidata*. —, SLENDER. *Leptochloa*. —, SMALL. *Microchloa*. —, SOFT. *Holcus*. —, SOUR. *Panicum leucophæum*. —, SPARROW. *Aspargus officinalis*. —, SPEAR. Pan. —, SPIKE. *Uniola*. —, SPIKED. *Triglochin*. —, SPIKED QUAKING. *Brizopyrum*. —, SPRING. *Anthoxanthum*. —, SPURT. *Scirpus maritimus*. —, SQUIRREL-TAIL. *Hordeum jubatum*. —, STANDER. *Orchis mascula*. —, STAR. *Callitriche*; also an American name for *Hypoxys* and *Aetia*. —, STRIPED. *Digraphis arundinacea variegata*. —, SWEET. *Glyceria*. —, SWINE'S. *Polygonum aviculare*. —, SWORD. *Gladiolus*; also *Arenaria segetalis*, and *Melilotus segetalis*. —, THIN. *Agrostis elata* and *perennans*. —, THREE-LEAVED. *Trifolium*. —, TIMOTHY. *Phleum pratense*. —, TRIPLE-AWNED. *Aristida*. —, TOAD. *Juncus bufonius*. —, TURTLE. *Zostera marina*. —, TUSSAC, or TUSsock. *Dactylis cæspitosa*. —, TWIG. *Rhynchospora*. —, TWO-PENNY. *Lysimachia Nummularia*. —, VANILLA. *Hierochloa borealis*. —, VEEVET. *Holcus lanatus*. —, VERNAL. *Anthoxanthum odoratum*. —, VIPER'S. *Scorzonera*. —, WATER SCORPION. *Myosotis palustris*. —, WATER STAR. *Lepanthus gramineus*. —, WHEAT. *Triticum*. —, WHITE. *Leersia virginica*. —, WHITELOW. *Draba*, especially *Draba verna*; also *Saxifraga tridactylites*. —, WILD OAT. *Danthonia*. —, WIND. *Apera Spica venti*. —, WIRE. *Elymus indica*, and *Poa compressa*. —, WIRE BENT. *Nardus stricta*. —, WOOD. *Sorghum* (*Audropogon*) *mitans*; also *Luzula sulcatra*. —, WOOD REED. *Cinna*. —, WOOLLY. *Lasiagrostis*. —, WOOLLY-BEARD. *Eriophorum*. —, WORM. *Spargelia*; also *Sedum album*. —, YARD. An American name for *Elymus*. —, YELLOW-EYED. *Xyris*.

GRASS-CLOTH PLANT. *Buhmeria nivea*.

GRASSETTE. (Fr.) *Pinguicula vulgaris*.

GRASS-GREEN. Clear, lively green, without any mixture.

GRASS OIL. An oil obtained from *Audropogon Iwarcusca*.

GRASS-TREE. *Xanthorrhoea*; also *Richea dracophylla*, and *Kingia australis*.

GRASS-WRACK. *Zostera marina*.

GRATIA DEI. *Gratiola officinalis*.

GRATIOLA. A genus of *Scrophulariaceae*, consisting of perennial herbaceous plants, found wild in central Europe, North America, and extra-tropical Australia. The flowers have a calyx of five equal divisions, a tubular corolla whose limb is two-tipped, the upper lip notched or cleft into two divisions, the lower three-cleft; four stamens, two of which are sterile and longer than the fertile; and a capsular fruit. *G. officinalis*, the Hedge Hyssop of the herbalists, was in former times called *Gratia Dei*, on account of its active medicinal properties. It is a bitter purgative and emetic, and is even poisonous in large doses. It is not used in medical practice in this country, but is said to have formed the basis of a famous nostrum for gout called Eau medicinale. Haller says that the abundance of this plant in some of the Swiss meadows renders it dangerous to allow cattle to feed in them. *G. peruviana* has similar properties. [M. T. M.]

GRATIOLE. (Fr.) *Gratiola officinalis*.

GRATTERON. (Fr.) *Galium Aparine*.

GRAVELIN. (Fr.) *Quercus pedunculata*.

GRAVEL-ROOT. *Eupatorium purpureum*.

GRAVEOLENS. Strong-scented; having a smell which is unpleasant because of its intensity.

GRAVESIA. A genus of Madagascar *Melastomaceae*, of which *G. bertolonoides* is a nearly stemless hairy herb, with opposite ovate five to seven ribbed crenelled leaves, and flower-stalks arising from the axis bearing an umbel of flowers which have a top-shaped five-toothed hairy calyx, five ovate petals, and ten stamens of equal length, with the connective, produced below into an obtuse spur-like appendage. This latter character serves to distinguish the genus among its near allies. [A. A. B.]

GRAWATHA. Curra-tow, the fibre of *Bromelia* (or *Ananasia*) *Sagenaria*, which is twisted into ropes.

GRAYA. A genus of *Chenopodiaceae*, comprising a North American erect branched spiny shrub with solitary or fascicled oblong-lanceolate entire fleshy leaves and dioecious flowers. The male flowers have a regular five-parted perigone and five stamens; the females a monosepalous perigone, compressed and winged, notched at the apex, and bulging above the middle within, and a subulate style with two filiform stigmas. [J. T. S.]

GREEDE. *Potamogeton*.

GREENBRIER. An American name for *Smilax*.

GREENGAGE. A delicious variety of plum.

**GREENHEART TREE.** *Nectandra Bodin.*

**GREEN-MAN.** *Aceras anthropophora.*

**GREENS.** The familiar domestic name for open-hearted Cabbages, Kale, and other leafy esculents; also applied to *Lenina*.

**GREENWEED, or GREENWOOD.** *Genista tinctoria* and *pilosa*.

**GREENWITHE.** *Vanilla claviculata.*

**GREGGIA.** A genus of *Cruciferae* from New Mexico, discovered by Dr. Gregg, who died in California through over-exertion in scientific pursuits. This plant, called *G. camporum* from its growing on the Canyons or plains, has the habit of a wallflower, and all its parts clothed with hoary pubescence. The stems are furnished with alternate spatulate sinuate leaves, and the pink or white flowers, somewhat like those of the Brompton stock but smaller, are disposed in loose terminal racemes. The narrowed pods (siliques) are about an inch long and flattened laterally, so that the valves are boat-shaped. The genus differs from others of the *Lepidium* group, by its long pods, and from its nearest allies in having incumbent cotyledons. [A. A. B.]

**GREGRE TREE.** *Erythrophloeum guineense.*

**GREGORIA.** A genus of primworts, having a five-cleft bell-shaped calyx; a salver-shaped corolla, its tube dilated at the upper end, with a border of five spreading lobes, and five ovules, two only of which reach maturity. The only species is a small herb formerly known as *Aretia Pyrenaica*, a native of the Pyrenees. [G. D.]

**GRÉMIL.** (Fr.) *Lithospermum officinale.*

**GREMILLET.** (Fr.) *Myosotis.*

**GRENADIER.** (Fr.) *Punica Granatum.*

**GRENADILLE.** (Fr.) *Passiflora.*

**GRENADIN.** (Fr.) *Dianthus Caryophyllus.*

**GRENIERA.** A genus of *Caryophyllaceae* which it has been proposed to separate from *Alysia* on account of the seeds being much compressed, with a transparent wing round the back, and a thin layer of albumen above the peripheral embryo. *G. Douglasii* and *tenella* are slender herbs from California and Arkansas, with the habit of *Alysia verna* and *tenuifolia*. [J. T. S.]

**GRENOUILLETTE.** (Fr.) *Ranunculus acris*, and others.

**GREVILLEA.** A genus of *Proteaceae*, distinguished by having apetalous flowers; a calyx which is either four-cleft or has four linear sepals broadish at the end; four ovate sessile anthers, one of which is attached to the concave apex of each sepal; and an elongated curved style, with the stigma either lateral or oblique, plane or concave. The seed-vessel, called a follicle, is woody or leathery, containing one or two occasionally winged oval seeds. This is the most extensive and also the handsom-

est genus of the order. It contains every variety of form, from lofty trees a hundred feet in height, with a girth of eight feet, as in *G. robusta*, the Silk Oak of the colonists, to humble procumbent shrubs, as in *G. lanceifolia*. The foliage is equally varied: in *G. juniperina*, *ericifolia*, &c., it is needle-shaped; in *G. glabella* and *junciifolia*, it is filiform; in *G. obliqua*, *polystachya*, and *Leucadendron*, it is linear, twelve to eighteen inches in length; in *G. asplenifolia* and *mnemosodes*, it is linear and serrated; in *G. laurifolia* it is ovate and entire; in *G. angulata* and *agrifolia* it is rounded at the apex, wedge-shaped and serrated; in *G. thicifolia*, *acanthifolia*, and *Cunninghamii*, it is deeply cut, with sharp prickly teeth; in *G. cinerea* and *buxifolia*,

*Grevillea acanthifolia.*

box-leaved; in *G. anethifolia* and *tritermala*, tritermala; in *G. Gaudichaudii*, *Aquilifolium*, *Sturtii*, &c., pinnatifid; in *G. Banksii*, *Caleyii*, *robusta*, &c., pinnate or bipinnatifid. The inflorescence is in spikes generally of a deep rich red, occasionally yellow as in *G. sulphurea*, *Banksii*, and *Chrysodendron*. In the latter species the flower-spikes exceed one foot in length, and are extremely beautiful. In *G. Dryandri*, *asplenifolia*, *Caleyii*, and *robusta*, the flowers are also in long spikes, of a deep colour. The seed-vessels in the following species are of a hard woody substance, nearly spherical, from an inch to two inches in diameter, viz. *G. refracta*, *mnemosodes*, and *Leucadendron*, and especially *G. gibbosa*; these are all either tropical or subtropical plants. [With the exception of three or four New Caledonian species, the genus is limited to Australia; two or three being found in Tasmania.] [R. H.]

**GREWIA.** An extensive genus of *Tillaceae*, consisting of shrubs or small trees, with simple usually serrated leaves, natives of the tropical and subtropical regions of the Asiatic and African continents, and also of the islands of the Malayan Archipelago, the Fijijs, &c., but not found on the

American continent. The flowers have five sepals, which are coloured (not green) on the inside and often hairy outside; and five petals, each with a gland or hollow at the base inside, and inserted at the bottom of the stalk-like receptacle of the three to four-celled ovary, while the numerous stamens are inserted round its summit. The fruit consists of from one to four stones, each containing one or two seeds. Upwards of eighty species of this genus are described.

*G. asiatica* and *sapida* have both small red fruits, which, on account of their pleasant acid taste, are commonly used in India for flavouring sherbets. The wood of the Dhamnoco, *G. elastica*, a species common in the Himalayas, is very strong and elastic, and is consequently much prized by the natives for making their bows, besides which it is used for carriage-shafts and other purposes where elasticity is requisite. At the Cape of Good Hope, the elastic wood of *G. occidentalis*, called Kruysbeesje, is used for similar purposes. Most of the species have a fibrous inner bark, which is commonly employed by the natives for making fishing-nets, ropes, twine, &c. [A. S.]

**GRIAS.** A genus of *Barringtoniaceæ* peculiar to the West Indies and the adjoining mainland. The Anchovy Pear of Jamaica, *G. cauliflora*, has long been cultivated in plant-stoves for the sake of its magnificent foliage. It is a slender tall unbranched tree, furnished at top with a large crown of drooping glossy-green alternate lance-shaped or spatulate entire leaves, which are sometimes upwards of three feet long. The flowers (not well known) are said to be large, white, arranged in clusters which arise from the old wood, and consisting of a superior four-toothed calyx, four rounded petals, numerous stamens in five rows with their stalks united at the base, and an ovary tipped with a cruciform sessile stigma. The fruits are said to be russet-brown drupes, and to be pickled and eaten like the mango, having a similar taste. *G. Fendleri*, found in Panama, with equally handsome leaves, has its flowers in short racemes arising from the trunk, yellow, and one to two inches across. [A. A. B.]

**GRIFFINIA.** A small genus of South American *Amaryllidaceæ*, consisting of dwarfish bulbous plants, with broad oblong petiolated nervose leaves, and a many-flowered umbel of handsome purplish flowers. The perianth has a short cylindrical declinate tube, and unequal reflexed limb of six segments, the lower of which are divaricate, and the lowest stretched forward; there are six stamens with thread-shaped filaments, one of them ascending, the rest declinate; and a three-celled ovary, containing two collateral ovules in each cell, and tipped by a three-furrowed style, and an undivided or obsoletely three-lobed stigma. *G. Ayacastina*, the best known species, grows in woods on the hills behind Rio Janeiro, and is a very ornamental [T. M.]

**GRIFFITHIA.** An Indian shrub of the *Cinchona* family, with glandular leaves and spiny stems; flowers white, in terminal clusters, with a funnel-shaped corolla, whose throat is hairy, and whose limb is divided into five oblong acute segments; ovary two-celled, surmounted by a fleshy disk; stigma undivided striated. The fruit is succulent and reddish. [M. T. M.]

**GRIGG.** *Calluna vulgaris*.

**GRIGNON.** (Fr.) The wood of *Bucida Buceras*.

**GRIGRI.** A name in Trinidad for the wood of *Astrocaryum aculeatum*.

**GRIMMIA.** A genus of acrocarpous mosses, distinguished, as now reduced, by the columella not adhering to the lid, the short even tip of the veil which is entire and not lacerated at the base, and the generally exerted capsule. The peristome, when present, consists of sixteen large lanceolate convex teeth, which are split once or twice. *G. pulvinata*, remarkable for its curved peduncle, from whence it obtained formerly the name of the Swan's-neck Bryum, forms cushion-like tufts, hoary with the long white hair-points of the leaves, and thickly studded with fruit. The other British species are either Alpine or subalpine. [M. J. B.]

**GRIMMIEI.** A natural order of mosses, with an equal often sessile capsule, a single peristome, a mitreiform calyptra, and leaves of a dark green, always terminated by a white hair, and formed of punctiform cells. *Schistidium*, in which the columella is adnate with the lid, and the capsules are immersed; *Grimmia*, with its free lid; and *Racomitrium*, with its straggling habit, confirmed by the awl-shaped granulated beak of the veil, are the British genera. *Driptodon* differs from *Racomitrium* merely in its forked stems and fastigate innovations, and is generally united with that genus. They are found in various climates, *Schistidium opocarpum*, which is one of our more common mosses, appearing also both in Asia and South America. [M. J. B.]

**GRINDELIA.** A genus of *Compositæ* numbering upwards of a dozen species. The prairies of the Saskatchewan are their northern limit, Patagonia the southern, and they are found in greatest plenty in Texas and Mexico. Their chief distinguishing feature is the pappus, which consists of from two to eight rigid narrow awns, which fall early. They are biennial or perennial suffrutescent plants, with branching stems, spatulate radical leaves, and sessile or clasping cauline ones, and yellow flower-heads, solitary at the ends of the twigs, and from one to two inches across. Most of the species have all their parts more or less covered with a glutinous varnish when young. [A. A. B.]

**GRIOT, GRIOTTE, or GRIOTTIER.** (Fr.) Names applied to varieties of *Cerasus vulgaris*.

**GRISAILLE**, or **GRISARD**. (Fr.) *Populus canescens*.

**GRISEBACHIA**. A genus of heath-works, distinguished by the following marks:—calyx bell-shaped, and slightly four-angled; corolla scarcely longer than the calyx; filaments covered with stiff hairs; the style ending in a small, very blunt stigma; seed-vessel compressed, two-celled, two-seeded. The genus was named in honour of Grisebach, a German botanist. The species are heath-like shrubs, natives of the Cape. [G. D.]

**GRISELINIA**. A genus of *Cornaceae* nearly allied to *Lucuba*, which it also resembles in habit, and containing eight New Zealand, Chilean, and Brazilian species. The flowers are small, dioecious, in terminal panicles, the males with five stamens, the females with an inferior ovary of one or two cells, but with three stigmas. The fruit is a berry with a single pendulous seed. One or two species are met with in gardens as half-hardy evergreen shrubs.

**GRISSET**. (Fr.) *Zippophias rhamnoides*.

**GRISEUS**. Pure grey, a little verging to blue.

**GRISLEA**. A genus of *Lythraceae* [now limited to *G. secunda*, a native of Venezuela and New Grenada. The name is, however, best known in connection with *G. tomentosa*, now called *Woodfordia tomentosa*], a very common East Indian species, with sessile lance-shaped entire leaves clothed with white down underneath, and pretty scarlet fuchsia-like blossoms arranged in axillary cymes, and consisting of a tubular coloured calyx with a four to six-toothed border, and a like number of green glands in the clefts, four to six small narrow petals, eight to twenty stamens protruded beyond the calyx tube, and an ovary tipped with a simple style. According to Roxburgh, the calyx tube, which closely invests the ripe capsules, does not lose its colour when withered, and thus the shrub has a gaudy appearance even when in fruit. The flowers, mixed with those of *Norinda*, are used as a dye called Dhare in India. [A. A. B.]

**GRIT-BERRY**. *Comarostaphylis*.

**GROATS**, or **GRITS**. The grain of the oat deprived of its husks.

**GROBYA**. A genus of epiphytial orchids of Brazil, having ovate pseudobulbs, with a few grassy ribbed leaves at their apex, and a drooping flower-scape proceeding from the base of the pseudobulb, and ending in a short raceme of yellow or greenish flowers tinged and spotted with purple. The lower connate crescent-shaped sepals are larger than the upper, the petals broader, forming a sort of helmet overhanging the lip, which is small and five-lobed at the apex, and the two bilobed pollen-masses have each a distinct candle attached to an oval gland. *G. Amherstiae* and *G. galensis* are the two known species, both in culti-

vation. The genus is named in compliment to Lord Grey, of Groby. [A. A. B.]

**GROMWELL**, or **GROMELL**. *Lithospermum officinale*. —, **FALSE**. *Oenomodium*.

**GRONOVIA**. A genus usually placed in *Loasaceae*, from most of the genera in which it differs in the flowers, having five instead of numerous stamens, and the ovary one instead of many ovules. The only known species, *G. scandens*, found in Mexico, and New Grenada, is a scandent herb very like the common bryony of our hedges. Its small yellow flowers have a funnel-shaped calyx with a five-toothed border, and near its base an accessory calyx of five small bracts; the five small petals are inserted on the calyx tube, and the fruit is a little indehiscent capsula, with one seed. [A. A. B.]

**GROS BLÉ**. (Fr.) *Triticum turgidum*. — **GOBET**. *Cerastium vulgare*.

**GROSEILLIER**. (Fr.) *Ribes*. — **À MA-QUEREAUX**. The cultivated varieties of *Ribes Uva crispa*. — **EPINEUX SAUVAGE**. The wild Gooseberry, *Ribes Uva crispa*.

**GROSIER**. The Scotch name of the Gooseberry.

**GROSSAILLE**. (Fr.) *Triticum*.

**GROSSE GRIOTTE**. (Fr.) *Cerasus vulgaris*. — **JONQUILLE**. *Narcissus odoratus*.

**GROSSIFICATION**. The swelling of the ovary after fertilisation.

**GROSSULARIACEÆ**. (*Grossularia*, *Rubiaceae*, *Courantaceae*). A natural order of calycifloral dicotyledons characterising Lindley's grossal alliance of epigynous Exogens. Shrubs often spiny, with alternate palmately-lobed leaves, without true stipules. Calyx superior, limb four to five-lobed; petals, small, five; stamens five; ovary one-celled with two parietal placentas; styles more or less united. Fruit a berry, crowned with the remains of the flower; seeds numerous, albuminous. Natives of the temperate parts of Europe, Asia, and America. Wholesome plants, often supplying edible fruits, such as the gooseberry, red currant, and black currant. The two genera, *Ribes* and *Polygona*, comprise about a hundred species. [Bentham and Hooker include the whole group in *Saxifragaceae*.] [J. H. B.]

**GROSSUS**. Coarse; larger than usual; thus *grossus crenatus* = coarsely crenated; *grossus serratus* = coarsely serrated.

**GROUNDHEELE**. *Veronica officinalis*.

**GROUNDSEL**. *Senecio*, especially *S. vulgaris*; also *Hyoscyamus Senecionis*. — **TREE**. *Saccharis halimifolia*.

**GROWING POINT**. The soft centre of a bud, over which the nascent leaves are formed; and all modifications of it.

**GRUBBIACEÆ**. A natural order of monochlamydeous dicotyledons, containing only the genus *Grubbia*, and referred by Lindley and others to the *Bruticeae* in the unbelial alliance of epigynous Exogens.

Some regard it as an order which should be placed between *Santalaceae* and *Burseraceae*, from the former of which it differs in habit and inflorescence, in the lobes of the stamens scarcely adhering at the base, in the form of the anthers, and in the bilocular ovary; and from the latter, in the want of lobes either to the calyx or corolla, the valvate aestivation, and the long embryo. [J. H. B.]

**GRUBBIA.** A genus of bruniads, distinguished by having hermaphrodite flowers in the axils of single bracts, and grouped in small heads with a two-leaved involucre; style very short, truncate at the end, which is slightly three-lobed. The species are Cape shrubs, with four-angled branches, and having the leaves in pairs, shortly stalked, narrow, acute, with their margins rolled back. [G. D.]

**GRUGRU.** A Trinidad name for *Astrocaryum vulgare*, and also *Acrocomia sclerocarpa*.

**GRUMIXAMEIRA.** One of the edible-fruited *Eugenia*s of Brazil.

**GRUMOUS.** Divided into little clustered grums; as the *fecula* in the stem of the sago palm.

**GRUVELIA.** A genus of *Boraginaceae* from Chili, with the fruit as in *Cynoglossum*, but the corolla tubular, five-toothed at the apex, and scarcely exceeding the calyx. It has the habit of an *Arenaria*, and slender leaves, the lower and middle ones opposite, the upper alternate. [J. T. S.]

**GUABINOBA.** The berries of certain Brazilian species of *Psidium*.

**GUACO.** *Aristolochia Guaco*. Besides this, which is the true Guaco, *Mikania Guaco* and *Aristolochia anguicida* have had the reputation of yielding this South American alexipharmic. —, MEXICAN. A poison obtained from a species of *Convolvulus*.

**GUAIACUM.** A genus of *Zygophyllaceae*, consisting of West Indian and South American trees, noted for the resin which they secrete, and the extreme hardness of their wood. They have pinnate leaves and blue flowers, which have a calyx of five unequal segments, five stalked petals, ten stamens, and a stalked five-celled five-angled capsule, sometimes by abortion two to three-celled.

*G. officinale* is an ornamental tree with pretty blue flowers. Its trunk yields the greenish-brown hard heavy wood, called by turners *lignum vitae*, which is used for blocks and pulleys, rulers, skittle-balls, and other purposes where hardness is required and weight is not an objection; the logs are imported from Jamaica. As is also the case with the laburnum, there is great difference in the colour of the old or heart wood and that of the young or sap wood, which is of a light yellow colour. The fibres of this wood are cross-grained. The resin, commonly called gum guaiacum, exudes from the stem, and is also obtained

by jaggings or notching the stem and allowing the exuding juices to harden; or by boring holes in logs of the wood and then placing them on a fire, so that the resin is melted and runs through the hole into a calabash put to receive it; or in small quantities by boiling the chips in salt and water, when the resin floats on the top and may be removed. Guaiacum is greenish-brown, with a balsamic fragrance, and is remarkable for the changes of colour which it undergoes when brought into contact with various substances. Gluten gives it a blue tint, and hence guaiacum has been proposed as a test of the goodness of

*Guaiacum officinale*.

wheaten bread, which contains gluten. Gum arabic, milk, various roots, &c., as those of the carrot, potato, colchicum, and horseradish, possess a similar property. Nitric acid and chlorine change guaiacum successively to green, blue, and brown. These changes in colour are said to be due to the absorption of oxygen by guaiacic acid, the active principle of guaiacum. The resin, as well as the bark and wood, are used medicinally as stimulants in chronic rheumatism; skin diseases, and other complaints. *G. sanctum* is used for like purposes in the West Indies, where also the leaves are used as a substitute for soap, having strong detergent properties. [M. T. M.]

**GUAIABARA.** *Coccoloba uvifera*.

**GUAIAVA.** *Psidium*.

**GUALLAGA.** A West Indian name for *Zamia media*.

**GUANDEE.** *Cajanus indica*.

**GUAO.** A West Indian name for *Comocladia dentata*.

**GUARANA.** A substance prepared in South America from the seeds of *Paulinia sorbilis*, which are pounded into a paste called guarana bread, and hardened in the sun. It is used as a remedy for various diseases, as well as to form a most refreshing beverage.

**GUARANENE.** A white crystalline

bitter substance, obtained from guarana, nearly identical with theine and caffeine.

**GUAREA.** The vernacular name, in Cuba, of a meliaceous tree, the flowers of which are in axillary clusters, with the stamens united into a cylindrical or somewhat prismatic tube, the free margin of which is entire or slightly waved, the anthers being enclosed within it. The ovary is four-celled, placed on a stalk-like disk, and the capsule is four-valved, with four or eight seeds. The trees of this genus are more or less purgative and emetic in their effects. *G. trichitoides* and other species have a musk-like perfume. Some of them present a peculiarity in the growth of their leaves which are pinnate; after a while the lower leaflets fall, and young ones grow at the end of the same leaf-stalk, which elongates, the lower older portion becoming woody, with an outer bark and a semblance of pith within—assuming in fact the characters of a branch. [M. T. M.]

**GUATTERIA.** A genus of *Anonaceæ*, named in honour of an Italian botanist, and consisting of trees or shrubs with lateral or terminal inflorescence. The flowers have six petals in two rows, flat oblong or linear, and all of the same form, and the carpels are distinct, each containing a single erect seed. *G. virgata* is said to yield some of the light wood used by coachbuilders under the name of Lancelwood; see also **DOUVERTIA**. *G. longifolia* is an ornamental tree, commonly planted by roadsides in Bengal. *G. suberosa*, which has cork-like bark, is a native of Ceylon and various parts of India. [M. T. M.]

**GUAVA.** *Psidium pyriferum, pomiferum, &c.*

**GUAZA.** The narcotic tops of the Indian hemp, *Cannabis sativa indica*.

**GUAZUMA.** A genus of shrubs or small trees of the *Sterculiaceæ*, nearly allied to *Theobroma*, but differing in their woody tubercular fruits of the size of a hazel-nut, the entire instead of two-lobed appendage at the ends of the petals, and in their whole appearance. They are found in the East Indies and the islands of Eastern Africa, but are most frequent in tropical America. The leaves are like those of the elm, and their small white pink or yellow flowers are borne in axillary cymes. *G. tomentosa* is common in India and America. The French colonists in the West Indies call it Orme d'Amerique, from its resemblance to the elm. According to M'Fadyen, it grows in Jamaica to a height of twenty to twenty-five feet, and is allowed to grow in pasture lands, not only for the sake of its shade, but because the cattle feed and thrive on the foliage and fruit. The latter, coarsely bruised, are given to horses as a substitute for corn, their nutritive properties being attributed to the mucilage which abounds in them, and also in the inner bark. This mucilage is given out abundantly on infusion or decoction in water, and, according to the same authority, has been em-

ployed as a substitute for gelatine or albumen, in clarifying cane juice in the manufacture of sugar. A like infusion is given internally as a remedy for cutaneous diseases. The timber is light, splits readily, and is employed for the staves of sugar hogsheads. The plant is known by the name of Bastard Cedar to English colonists in Jamaica. A strong fibre is obtained from the young shoots of the same species in India. Cord made from it was found by Dr. Roxburgh to break at 100 lbs. when dry, and at 140 lbs. when wet. [A. A. B.]

**GUÈDE.** (Fr.) *Isatis tinctoria*.

**GUÊPES VÉGÉTANTES.** A name applied to a species of wasp in the West Indies, when affected by *Cordiceps aphecephala*. The parasite has a long cylindrical curved stem with a club-shaped head, and at length weighs down and kills the wasp. The accounts of earlier observers, who affirmed that they had seen the wasps flying about with their heavy burden, were long disbelieved, but they have been confirmed by more recent authorities. The fungus does not seem to fructify till after the death of the insect. We have at least seen no perfect individuals. [M. J. B.]

**GUERNÉSIENNE.** (Fr.) *Nerine sarniensis*.

**GUETTARDA.** A genus of shrubs or small trees, natives of tropical America and Asia, and belonging to the *Cunchnaceæ*. The corolla is salver-shaped, with a cylindrical tube, and a limb divided into four to nine oblong segments; anthers four to nine, sessile, concealed within the corolla; ovary with from four to nine compartments, each containing a single erect ovule. The fruit is succulent, with a bony four to nine-celled stone. [M. T. M.]

**GUEULE DE LION, or DE LOUP.** (Fr.) *Antirrhinum majus*.

**GUI.** (Fr.) *Viscum album*.

**GUIGNE ROUGE, or GUIGNIER.** (Fr.) *Cerasus avium*.

**GUILANDINA.** A small genus of leguminous plants found in nearly every tropical country, particularly upon the sea-shore, its extensive distribution being caused by the transportation of its seeds (which have an exceedingly hard impervious shell) from one country to another by means of oceanic currents. There are three or four species, which form prickly trailing shrubs ten or twelve feet or more in height, having twice pinnated leaves, the stalks covered with short down and bearing recurved prickles on the under side. The flowers are of a rusty yellow colour, and are borne in racemes; they have a five-parted calyx with a short tube, and a corolla of five nearly equal-sized petals, the stamens being ten in number, distinct, and hairy at the base. The pods, which are about two or three inches long, flattened, but bulged out in the centre, and covered with prickles, contain one, two, or three large bony seeds. *G. Bonduc* has solitary

prickles on the leaves, and the seeds are yellow. *G. Bonducella* differs by its prickles being in pairs, and its seeds lead-coloured. The seeds of both are very hard, and beautifully polished, and are called Nicker nuts or Bonduc nuts, the latter word being derived from the Arabic, *Bondog*, signifying a necklace, the seeds being commonly strung into necklaces, bracelets, rosaries, &c. The kernels have a very bitter taste, and are employed by Indian doctors as a tonic and febrifuge. The roots also are said to possess similar properties: indeed, the Singhalese employ every part of these plants medicinally. The oil obtained from the seeds is supposed to be useful in convulsions and palsy. [A. B.]

**GUILDINGIA.** A group of melastomads now referred to *Mouriria*.

**GUILIELMA.** A genus of palms confined to the tropical regions of South America, and containing three species, which have tall slender trunks marked with circular scars and armed with exceedingly sharp black spines. The large pinnate leaves have spiny leaflets and footstalks. The flower spikes are simply branched, and bear male and female flowers mixed together. The fruit is large and egg-shaped, containing a single seed.

*G. spectosa*, the Peach Palm, a native of Venezuela and Guiana, is cultivated on the banks of the Amazon and Rio Negro. It grows sixty or eighty feet high, and has its stems armed with rings of long sharp needle-like spines. The fruits, which are borne in large drooping bunches, are about the size of apricots, and of a bright scarlet colour at the top passing into bright orange below; their fleshy outer portion (sarcocarp) contains a large quantity of starchy matter, which forms a considerable portion of the food of the natives. They are either boiled or roasted, and when eaten with salt resemble a potato in flavour; or they are sometimes eaten with molasses. A beverage is also prepared by fermenting them in water; and the meal obtained from them is made into cakes. The wood of old trees is black, and so exceedingly hard that it turns the edge of an ordinary axe. [A. B.]

**GUILNO.** (Fr.) *Bromus catharticus*.

**GUIMAUVE.** (Fr.) *Althæa officinalis*. — **EN ARBRE.** *Hibiscus syriacus*.

**GUINCHE.** (Fr.) *Molinia cærulea*.

**GUINDOLLE, or GUINDOUX.** (Fr.) *Cercasus vulgaris*.

**GUINEA-HEN FLOWER.** *Fritillaria meleagris*.

**GUINEA-HEN WEED.** *Petiveria alliacea*.

**GUIRILA.** The Persian insect-powder, prepared from *Pyrethrum carneum*, and *P. roseum*.

**GUIZOTIA.** A small genus of annual opposite-leaved composite herbs found in Abyssinia and India, and nearly related to *Heliotropis*, differing chiefly in the presence

of a ring of thick jointed hairs outside the corolla tubes near the base. *G. oleifera*, a plant with the habit of *Bidens cernua*, has lance-shaped stem-clasping leaves, and solitary stalked yellow-rayed flower-heads about an inch and a half across at the ends of the twigs; the ray florets female, the disk florets perfect; the achenes smooth and destitute of pappus. The plant is cultivated in Abyssinia and in India for the sake of a bland oil like that of *Sesamum*, which is expressed from the seeds, and is commonly used in India as a lamp-oil and as a condiment. The plant is sown in the Mysore districts in the autumn months, perfecting its seeds in about twelve weeks after it is sown. The yield is said to be about two bushels an acre. The oil is sweet-tasted, and is known in India as Ram-till oil. [A. A. B.]

**GUJ-PIPPUL.** *Scindapsus officinalis*.

**GULF WEED** (called also by voyagers Sea-lentils, Sea-grasses, and Sargazo) is the celebrated *Sargassum bacciferum*, which occupies a more or less interrupted space between the 20th and 45th parallels of north latitude, extending over more than a quarter of a million of square miles. It was first discovered by Columbus, unless indeed the Phœnicians fell in with it during their early voyages, as seems possible from a passage in Aristotle. The seaweed floats on the surface, being propagated from age to age by buds, and never in that situation yielding fruit, which when produced consists of little bundles of receptacles in the axils of the leaves. The area occupied by the seaweed is determined by the course of the currents in the Atlantic, and occasionally a few stragglers are carried northward by the Gulf Stream, and are thrown even upon our own coasts. The origin of this mass of seaweed has not been determined. Its increase in deep water is, however, the less surprising if we remember that the root of seaweeds merely performs the office of a holdfast, and has not the function of a true root. [M. J. B.]

**GUM, ACAROID.** A resinous product of *Xanthorrhæa hastilis* or *arboræa*. — **AMMONIACUM.** The gum-resin of *Dorema ammoniacum*. — **ANIME.** A resinous product of *Trachytobium* and *Eymenan*; also Indian Copal, the produce of *Vateria indica*. — **ARABIC.** The gummy product of various *Acacias*, as *vera*, *arabica*, *Yerek*, *Seyal*, *Senegal*, *tortilis*, &c. — **ARTIFICIAL.** Dextrine, obtained from potato starch. — **AUSTRALIAN.** A kind of gum arabic. — **BABOOL.** The gum of *Acacia arabica*. — **BARBARY.** The gum of *Acacia gummiifera*. — **BASSORA.** A gum whose origin is unknown; it is supposed to be the produce of a *Cactus* or a *Mesembryanthemum*. — **BLACK-BOY, or BOTANY-BAY.** A fragrant resinous product of *Xanthorrhæa arborea* or *hastilis*. — **BRITISH.** A preparation of roasted starch. — **BUTEA.** Bengal Kino, the gum-resin of *Butea frondosa* and *superba*. — **CAPE.** The gum of *Acacia Karroo* or

*capensis*. —, CARANA. The gum-resin of *Isica Carana*. —, CASHEW. The gum of *Anacardium occidentale*. —, CEDAR. A gum-resin resembling oilbalm, obtained in the Cape Colony from *Widdringtonia juniperoides*. —, CHERRY-TREE. The gum produced from the stems of *Cerasus avium* and *vulgaris*, *Prunus domestica*, and other drupaceous trees. —, COPAL. A gum-resinous product of *Trachylobium Bonemannianum* and perhaps other species. —, DOCTOR'S. The gum-resin of *Rhus Metopium*. —, DRAGON. The gum-resin of *Pterocarpus Draco*; also the name sometimes given to gum tragacanth in the shops. —, EAST INDIAN. The gum of *Acacia arabica*, probably. —, ELASTIC. Ocoteouchou, the product of *Siphonia elastica*. —, ELEMI. The gum-resin of *Amyris Plumieri* and *hexandra*. —, GRASS-TREE. The resinous product of *Xanthorrhoea australis*. —, GUTTA, American. The gum-resin of *Viomea guianensis*. —, GUAIACUM. The gum-resin of *Guaiacum officinale*. —, HOG. A gum-resinous juice variously ascribed to *Moronea coccinea*, *Rhus Metopium*, *Clusia flava*, and *Hedwigia balsamifera*. —, JUNIPER. The resin of *Callitris quadrivalvis*. —, KINO. The gum of *Pterocarpus erinaceus*, and according to some of *Pterocarpus Marsupium*; also a similar product of *Eucalyptus resinifera*. —, KUTEERA. The gum of *Cochlospermum Gossypium*, or according to others of *Sterculia wrens*, or of *Acacia leucophloea*. —, LAO. The gummy product of *Erythrina monosperma*, and in Ceylon of *Aleurites lacifera*; a similar product is yielded by *Ficus indica*, *dengkalaensis*, &c. —, LADANUM. The gum-resinous product of *Cistus creticus*; also of *C. ladaniferus* and *Ledon*. —, LEDON. *Cistus Ledon*. —, MOROCCO. The gum of *Acacia gummifera*. —, MYRRH. The gum-resin of *Balsamodendron Myrrha*. —, OPOCALPASM. The gum of *Acacia gummifera*. —, ORENBURG. A gummy exudation of the larch, *Abies Larix*. —, SANDARACH. The resin of *Callitris quadrivalvis*. —, BASSA. A kind of false tragacanth obtained from *Inga Sassa*. —, SENEGAL. The gum of *Acacia Senegal*, *Seyal*, *Verak*, *Adansoni*, &c. —, SOUDAN. A kind of gum arabic. —, SUCCORY. The gummy juice of *Chondrilla juncea*. —, SWEET. *Liquidambar styraciflua*. —, THUR. A kind of gum arabic. —, TRAGACANTH. The gummy exudation of *Astragalus gummifer*, *strobiliferus* or *Dicksoni*, *versus*, *creticus*, and *aristatus*. —, TRAGACANTH of Sierra Leone. The gum of *Sterculia Tragacantha*. —, TURKEY. The true white gum arabic. —, WATTLE. The gum of *Acacia mollissima*. —, YELLOW. A resinous product of *Xanthorrhoea hastilis* or *arborescens*.

**GUM-TREE.** *Eucalyptus*; also *Xanthorrhoea*. — of Jamaica. *Hippomane biplanulosa*. —, BLACK. *Nyssa villosa*. —, BLUE. *Eucalyptus globulus*. —, RED. *Eucalyptus resinifera*. —, SOUL. *Nyssa villosa* and *biflora*. —, WHITE. *Eucalyptus resinifera*. —, YELLOW. *Nyssa villosa*.

**GUM-ARABIC TREE.** *Acacia Verak*. —, RED. *Acacia Adansoni*.

**GUM-WOOD.** The timber of *Eucalyptus*. **GUMBO MUSQUÉ.** The seeds of *Abelmoschus moschatus*.

**GUNDALI.** An Indian name for *Pedicularis fatida*.

**GUNGUN, or GUNJUN.** A balsamic product of *Dipterocarpus lavis*.

**GUNJA.** *Abrus precatorius*.

**GUNJAH.** The dried Indian Hemp plant, *Cannabis sativa indica*.

**GUNNALA.** An Indian name for *Cassia fistula*.

**GUNNERA.** [A genus belonging to the *Haloragaceae*, and distinguished by having the calyx three or four-lobed; petals two or none; stamens one or two; ovary one-celled; ovule solitary; stigmas two, subulate. The flowers are in racemes, panicles, or spikes.] The name was given by Linnaeus in honour of Ernest Gunner, a bishop of Norway, who published a flora of that country. There are eleven known species natives of various countries, as S. Australia, Tasmania, New Zealand, Sandwich Islands, Java, Abyssinia, Juan Fernandez, the Andes, and Antarctic S. America. Two of them, *G. scabra* and *G. manicata*, are known in gardens by their coarse rough rhubarb-like lobed leaves, and singular elongated conical inflorescence. [G. D.]

**GUNNIA australis** is the only epiphytal orchid of Tasmania, where it is found growing on the stems of trees and shrubs. It is a little plant, hardly a span high, with wiry roots, a few lance-shaped leaves three to four inches long, and flower-racemes of about the same length. The flowers, which smell like honeysuckle, are small and green except the clawed lip, which is marked with lilac lines on a white and yellow ground. As a genus it is hardly different from *Sarcocolla*, with which, indeed, it is united by some authors. Named in honour of Mr. R. C. Gunn of Tasmania, who is well known in connection with the botany of that island. [A. A. H.]

**GUNNY.** A coarse kind of cloth made from jute, the fibre of *Corchorus capsularis*, and sunn, the fibre of *Crotalaria juncea*.

**GURTIA.** A genus of *Begoniaceae*, consisting of erect branching shrubs, natives of Brazil. The flowers are cymose, the staminate and pistillate ones in the same plant; the former have four white perianth leaves, and numerous stamens; the latter five unequal perianth leaves, and a three-winged ovary, with a bifid stigma surrounded by a papillose band which is twice spirally twisted. There are four species. [J. H. B.]

**GUSTAVIA.** A genus of *Barringtoniaceae* peculiar to tropical America, and consisting of trees or shrubs with large handsome alternate ovate or spatulate glossy leaves, and showy white flowers

sometimes five or six inches across, tinged with pink, not unlike those of some *Magnolias*, and disposed in racemes or umbels at the ends of the twigs. They consist of a top-shaped calyx with an entire or lobed border, four to eight rounded or oval petals, very numerous stamens whose filaments are united below into a ring; and a four to six-celled ovary tipped with a short conical style and sulcate stigma. The fruits are somewhat fleshy and apple-like. The wood of *G. urceolata*, used for making hoops, is called Bois puant in Cayenne, because it becomes very foetid after exposure to the air. The small fruits of *G. speciosa*, according to Humboldt, when eaten, have the singular property of causing the body to assume a yellow colour, which, however, leaves it in the course of a day or two without any application. The bruised leaves of *G. brasiliensis* are said by Martius to have an unpleasant smell, and are used in cases of indurated liver. The roots are acrid, aromatic, and bitter; and the emetic fruit intoxicates fish. [A. A. B.]

**GUTHNICKIA.** The name of a few species separated from *Achimenes*. It forms one of the genera with a perigynous and nearly entire thickened ring, and a stomatophorous stigma. Among these it is known by the long gaping corolla, the tube of which is straight and subcylindrical, and by the stamens being adnate with the lower part of the corolla tube. They are hairy leafy Mexican herbs, with solitary axillary scarlet flowers. [T. M.]

**GUTIERREZIA.** A small genus of composite plants, of the same group as *Solidago*, and differing from its near allies in the achenes of the disk and ray florets being fertile and furnished with a pappus of several linear or oblong chaffy scales. They are peculiar to America, and extend from the prairies of the Red River to Mexico, a few occurring in Chili and the extreme south of the continent. For the most part they are branching herbs one to three feet high, with slender twiggy stems furnished with linear entire gummy leaves, and small yellow flower-heads very numerous, arranged in corymbs at the ends of the twigs. *G. gymnospermoides*, the only species with any pretensions to beauty, has flowers very much larger than the others, and not unlike those of *Pulicaria dysenterica*. [A. A. B.]

**GUTTA PERCHA.** The gum-resin of *Isandra gutta*. — **TRAP.** The inspissated sap of *Artocarpus*.

**GUTTATUS.** Spotted; that is, when colour is disposed in small spots.

**GUTTIFERÆ.** (*Olusiaceæ, Guttiferae*). — natural order of thalamifloral dicotyledons, belonging to Lindley's guttiferal alliance of hypogynous Exogens. Trees or shrubs with a resinous juice, opposite leathery entire leaves, and often incomplete flowers; sepals and petals two four five six eight, the former often unequal, the equilateral; stamens numerous,

often united; disk fleshy; ovary one of many-celled; stigma usually sessile and radiate. Fruit dry or succulent, one or many-celled; seeds exalbuminous, often immersed in pulp. Natives of humid and hot places in tropical regions, chiefly in South America. Several are found in India, a few in Madagascar and the continent of Africa. The plants are generally acrid, and yield a yellow gum-resin. Gamboge is produced by [*Garcinia Moralla*, and several varieties which were formerly considered species]. The famous mangosteen fruit is procured from *Garcinia Mangostana*. The American mammee apple is the produce of *Mammea americana*. Keena oil is obtained from species of *Calophyllum*. The *Clusia* are handsome trees. *Pentadesma butyracea* is the butter and tallow tree of Sierra Leone; its fruit yields fatty matter. There are 32 known genera and upwards of 150 species. Examples: *Clusia, Garcinia, Commobgia, Calophyllum*. [J. H. B.]

**GYONIA.** A genus of *Melastomaceæ*, bearing pentamerous flowers, having the teeth of the calyx acute, the petals ovate-innecolate, the stamens ten, equal, with ovoid blunt anthers, and the ovary five-celled. They are tender smooth herbs with prostrate and ascending stems, small rhomboid-ovate leaves, and small solitary rose-coloured flowers. *G. tenella* inhabits moist ground on the banks of the Senegambia rivers. [J. H. B.]

**GUZMANNIA.** A genus of tropical American herbs, belonging to the *Bromeliaceæ*, and having an inferior calyx of three equal segments cohering at the base and spirally twisted, three petals rolled together into a tube, the anthers also cohering so as to form a tube. The seeds are numerous, provided with hairs, and enclosed in a three-celled three-valved capsule. *G. tricolor* is a pretty species with flowers on a spike, concealed by the bracts, the lowermost of which are green, while the upper are scarlet. [M. T. M.]

**GYMNADENIA.** A genus of terrestrial orchids, founded on the *Orchis conopsea*, which has the pollen-masses not enclosed in any process of the stigma. Several other species of European and North American orchids have been associated with it by some botanists, whilst others retain them in *Orchis* or in *Habenaria*.

**GYMNANDRA.** A genus of *Selaginaceæ*, containing six species of herbaceous plants, natives of Siberia, Arctic America, and the mountains of India. The flowers grow in long spikes at the apex of an erect scape. The calyx is spathe-like, with a fissure in front, and two or three-lobed behind; the tubular corolla is two-lipped; there are two stamens; the free bilocular ovary bears a long exserted style and a stigma with two capitate lobes; and the fruit is surrounded by the withered bracts and calyx, and consists of two achenes each containing a cylindrical pendulous seed. The structure of the fruit of this genus separates it from *Scrophulariaceæ*, to which it

is otherwise nearly related. On the whole, it seems to belong to *Selaginaceae*, though differing remarkably from the other genera of the order. [W. C.]

**GYMNANTHERA.** A genus of *Asclepiadaceae*, containing a single species from New Holland, a twining glabrous shrub with milky juice, opposite leaves, and whitish-green flowers on lateral peduncles, having a salver-shaped corolla, and a staminal crown of five awned scales inserted at the summit of the tube and alternating with the corolla lobes. The capsule is cylindrical divaricate, and containing many comose seeds. [W. C.]

**GYMNOBALANUS.** Tropical American trees, constituting a genus of *Lauraceae*, and known by the following characters:—The perianth in both male and female flowers is divided into six nearly equal segments, and is deciduous; the male flowers have nine stamens in three rows, the inner row bearing sessile glands, a long style, and an abortive ovary; the females nine sterile stamens, a one-celled ovary, and a short style. The fruit is succulent, on a thickened flower-stalk. [M. T. M.]

**GYMNOCARPIUM.** *Polypodium*.

**GYMNOCIDIDIUM.** The swelling occasionally found at the base of the sporocarpium of urn-mosses.

**GYMNOCLADUS.** A large American tree, *G. canadensis*, called the Kentucky Coffee-tree, is the sole representative of this genus of leguminous plants. It is common throughout the Northern United States, and in Canada, where it is called Chicot; and is frequently cultivated, either as an ornamental tree, or for its timber, which is strong and of a compact fine grain, and used for building purposes, common cabinet-making, &c. It attains a height of fifty or sixty feet, the trunk being frequently destitute of branches for the first thirty feet, but seldom more than twelve or fifteen inches in diameter. Its leaves are twice pinnate, and sometimes as much as three feet in length, consisting of a main stalk with several pairs of secondary stalks bearing numerous oval dull-green leaflets, except the lowest pair, which have a single leaflet. The flowers are whitish and borne in racemes from the angles of the leaves, the separate sexes being on different trees; their calyx is tubular and five-cleft, and the corolla of five equal-sized petals inserted into the top of the calyx tube, along with the ten short distinct stamens. The fruit is a hard flattened pod, from six to ten inches long, containing several flatish seeds imbedded in a mass of pulp. The common American name of this tree was given to it in consequence of the early settlers in Kentucky having made use of its seeds as a substitute for coffee, at a time when they could not procure the genuine article. The rough bark of the tree is excessively bitter, and contains *saponins*, a substance which, like soap, forms a lather in water. [A. S.]

**GYMNOGENS, or GYMNOSPERMS.** Naked-seeded plants, forming a division of dicotyledons or Exogens considered by Lindley as a distinct class. It includes the *Coniferae* or pines and firs, *Taxaceae* or yews, *Gnetales* or joint-firs, and *Cycadaceae* or cycads. These orders are usually called naked-seeded because there is no proper ovary, the seeds being fertilized by the pollen coming into direct contact with the foramen of the ovule without the intervention of a stigma. Some authors have of late doubted the correctness of this statement, and have considered the so-called seeds as a bicarpellary ovary containing one seed. Gymnospermous plants are represented largely in the fossil flora of the secondary strata. [J. H. B.]

**GYMNOGRAMMA.** A genus of polypodiaceous ferns, having free forked veins and linear sori which are more or less frequently forked—that is to say, the sporocases, being distributed along a portion of the veins, are continued both above and below the points where the veins fork. The sori in some species are very much elongated, and form contiguous narrow lines over a great portion of the fertile fronds. In other species the under surface, and sometimes also the upper, is farinoseo ceraceous, and usually either of a white or yellow colour, these being the Gold and Silver Ferns so frequently seen in cultivation on account of the beauty of their coloured fronds. This genus contains two of the very few known annual ferns, *G. charophylla* and *G. leptophylla*, the first a West Indian plant, the second scattered over nearly the whole of the temperate regions of the globe from Jersey to New Zealand, and found also in the Nelligherries and Cuba. The other species are widely dispersed, but chiefly found in tropical countries. [T. M.]

**GYMNOGYNE** *cotuloides*, which is the only known species of the genus, is a slender composite annual weed, peculiar to West Australia. Its unbranched stems, furnished with grassy leaves, are terminated by a single flower-head the size of a pea, and somewhat like those of *Cotula*. The outer florets are female and destitute of corolla (whence the name); and the inner male, with a tubular four-toothed corolla, and free anthers. The genus is related to *Euphrosyne*, differing in the many series of female florets, the four-toothed males, and the imbricated achenes. [A. A. B.]

**GYMNOGYNOUS.** Having a naked ovary.

**GYMNOMESIMUM.** A genus differing but little from *Arum*, except in the presence of rudimentary flowers above the stamens, and not elsewhere. The ovaries contain several ovules. *G. pictum* is frequently met with in gardens under its former name of *Arum*. It is a native of Corsica, Sardinia, &c. [M. T. M.]

**GYMNOPETALUM.** The name of a genus of *Ocubritaceae*, allied to *Brasica*, and having a calyx with a contracted throat.

a five-parted corolla, anthers cohering into a cone, and an ovate beaked few-seeded fruit. [M. T. M.]

**GYMNOPOGON.** A genus of grasses belonging to the tribe *Chlorideæ*, having the inflorescence in panicles, with simple alternate brachlets; spikelets two-flowered; glumes two, keeled, nearly equal, or the lower shortest. There are about half a dozen species, all natives of Brazil excepting *G. racemosus*, which is North American. [D. M.]

**GYMNOPSIS.** A genus of composite plants, comprising about a dozen species, spread over America from Texas to Brazil. They are herbaceous or somewhat shrubby, with opposite three-nerved toothed nettle-like rough leaves, and axillary or terminal stalked yellow-rayed heads of numerous florets, those of the ray neutral, of the disk perfect. The achenes are seated on a convex receptacle, each enveloped in a chaffy scale and surmounted by a minutely toothed pappus-crown. The presence and nature of the pappus, together with the opposite triple-nerved leaves, are the chief features. [A. A. B.]

**GYMNOPTERIS.** A genus of polypodiaceous ferns belonging to the tribe *Pleurogrammeæ*, in which the linear-oblong sori are placed close to and parallel with the costa. In this group it is distinguished by its compoundly anastomosing veins, and by the fructification occupying distinct contracted fronds. The species have sometimes been referred to the *Acrosticheæ*, from which, however, the definite linear sori, confined to the receptacular veins, seem to separate them. They are all Eastern tropical plants. [T. M.]

**GYMNOS.** In Greek compounds = naked, or uncovered.

**GYMNOSCHÆNUS.** A genus of cyperaceous plants belonging to the tribe *Rhynchosporææ*. The inflorescence is in distichous two-flowered spikelets. Only one species is described, namely, *G. adustus*, a native of Van Diemen's Land. [D. M.]

**GYMNOSIPHON.** A small slender leafless herb, from the Indian Archipelago, forming a genus of *Burmanniaceæ*, scarcely differing from the tropical American genus *Dictyostegia*.

**GYMNOSPERMA.** A genus of *Compositæ*, receiving its name from its chief distinguishing feature, namely, the naked achenes (without pappus). The two species, found in Texas and Mexico, are smooth glutinous shrubby plants, with twigg stems furnished with linear entire leaves, and terminating in corymbs of numerous small yellow flower-heads, each containing from eight to fourteen florets, those of the ray strap-shaped and pistillate, and those of the disk tubular and perfect. [A. A. B.]

**GYMNOSTACHYS.** An East Australian perennial, with a thick rootstock, and grassy leaves, from among which rises a two-edged stalk or scape, bearing towards

its summit a number of clustered slender spikes or spadices, each having at its base a short keeled spathe; stamens four; ovary one-celled; fruit succulent, blue, one-seeded. *G. anceps*, the only species, is in cultivation. The genus is nearly allied to *Acorus*, and is included with it among *Orontiaceæ*. [M. T. M.]

**GYMNOSTACHYUM.** A genus of *Acanthaceæ* with the habit of *Branthemum* and *Cryptophragmium*. It comprises dwarf herbs, with spreading often variegated leaves, and erect spike-like racemes of tubular flowers. The calyx is five-parted nearly equal; the corolla two-lipped, with the upper lip bidentate; the stamens two, with the anther-cells parallel; the stigma bifid; and the capsule columnar and four-cornered. *G. ceylanticum*, a Ceylon species, is a pretty stove-herb, with the leaves variegated with white along the course of the veins; and *G. Verschaffeltii*, from Para, is a still prettier plant with the numerous reticulated veins coloured red, as occurs in *Hamadictyon venosum*. They are chiefly interesting on account of their prettily marked foliage. [T. M.]

**GYMNOSTEPHIUM.** A genus of composite plants peculiar to South Africa. The three known species are herbaceous or somewhat shrubby plants, with alternate linear entire leaves, and small solitary stalked flower-heads terminating the twigs, the ray florets strap-shaped and blue, the disk tubular and yellow. The achenes of the ray being without pappus, and those of the disk being sterile, suffice to distinguish these plants from daisies and their other allies. [A. A. B.]

**GYMNOSTOMUM.** A genus of acrocarpous mosses, formerly containing almost every moss destitute of a peristome, but now restricted to those species which differ only in this character from *Weissia*. The species mostly, though not exclusively, inhabit temperate regions. [M. J. B.]

**GYMNOSTYLIS.** Under the name of *G. anthemifolia* is sometimes cultivated in botanic gardens a stemless South American herb with chainomile-like leaves, and clusters of small woolly flower-heads sitting in their midst. The plant is usually placed in *Soliva*. [A. A. B.]

**GYMNOTETRASPERMOUS.** Having such a four-lobed ovary as is found in labiates, which was formerly thought to consist of four naked seeds.

**GYMNOTHECA.** A small genus of marattiaceous ferns, separated from *Marattia* on account of the absence of an involucre beneath the sorus. They are the same in habit and in general aspect, having large globose scaly rhizomes, and ample bipinnate fronds, with articulated pinnules. The typical species is *G. cicutafolia*. [T. M.]

The name has also been given to a Chinese herbaceous plant with the habit of *Saururus*, and referred to the *Saururaceæ*. The flowers are small, placed on spikes, in the axils of small somewhat fleshy bracts;

stamens six, inserted on the top of the ovary (1), which is inferior, one-celled, with four parietal placentae; ovules numerous; styles four. (*Decasium*.) [M. T. M.]

**GYMNOTRICH.** A genus of grasses belonging to the tribe *Panicæ*, joined by Steudel with *Pennisetum*. [D. M.]

**GYNAION.** A genus of *Cordiaceæ*, containing a single species from the Himalayas. It is a woody plant with alternate or sub-opposite elliptical entire leaves, and flowers in cymes at the ends of the branchlets. The calyx is unequally four to six-lobed; the corolla funnel-shaped, with the limb divided into four to six obovate-oblong lobes; the five stamens have hairy filaments; and the four-celled ovary is globose and glabrous, perforated at the apex, without style or stigma. This remarkable plant has the habit of *Varronia rotundifolia*, but differs from it in the structure of the flower, which seems to be the monstrous flower of a *Cordia* wanting the style and stigma; it differs from *Cordia* in the structure of the calyx and corolla. [W. C.]

**GYNANDROUS.** Having the stamens and style and ovary all blended into one common body, as in orchids, *Aristolochia*, &c.

**GYNERIUM.** A genus of grasses belonging to the tribe *Arundinæ*, and distinguished chiefly by the species having showy flower-panicles, the spikelets of which are two-flowered, the male and female flowers on distinct plants. Steudel describes six species, which are natives of Brazil and Chili, save one, *G. zelandicum*. That which is best known and cultivated in Britain is *G. argenteum*, the Pampas grass, so called from its being a native of the vast plains of South America called Pampas. This splendid grass has proved sufficiently hardy to withstand the rigours of our winters in Britain without protection; and blossoming as it does in October, when most other flowers are past, its value is much enhanced. Few plants produce a finer effect than good tufts of this grass, either when cultivated singly on lawns, or in the front of shrubberies, where evergreen plants afford a dark background, as a contrast to its large silvery-white feather-like panicles. Under favourable circumstances, the culms rise from ten to twelve feet high or upwards, forty, fifty, or occasionally more, springing from one plant. This Pampas grass was first introduced to Europe in 1843, through seeds sent from Buenos Ayres by Mr. Tweedie to the Glasnevin Botanic Garden, and it is now cultivated in most gardens of note throughout Great Britain, as well as on the continent of Europe, and in Australia. [D. M.]

**GYNIXUS, or GYNIZUS.** The depressed stigmatic surface of orchids.

**GYNOBASE.** The growing point inserted between the base of carpels in a conical manner, so as to throw them into an oblique position.

**GYNOCARDIA.** A genus of *Pangiaceæ*, differing from others in the very numerous stamens (about a hundred), and in the sterile flowers, whose anthers are fixed by the base. *G. odorata*, the only known species, is a handsome East Indian tree, abundant in hot valleys in the Sikkim Himalaya and Khasya, comparable to the common sycamore for size, having glossy entire alternate leaves, and yellow sweet-scented flowers an inch and a half across, growing in clusters generally from the old wood, the different sexes on separate plants. They have four or five calyx leaves, a like number of petals and scales opposite them, numerous stamens in the sterile flowers, and a few abortive ones in the fertile, surrounding an ovary which is tipped with five short styles. The fruits are globular ash-coloured berries the size of a shaddock, and enclose numerous seeds, imbedded in pulp. According to Roxburgh, the seeds contain an oil; and are beaten up with clarified butter, and used by the natives as a remedy for cutaneous diseases. [A. A. B.]

**GYNOCEPHALIUM.** A Japanese climbing shrub, belonging to the *Artocarpaceæ*. The leaves are heart-shaped and undivided; the female flowers are globular, the male in panicle heads. The genus is closely allied to *Conocephalus*, but is distinguished from it by the four-parted perianth of the male flower, the cleft style, and the crumpled seed-leaves. [M. f. M.]

**GYNECIUM.** The pistil and all that belongs to it.

**GYNOPHORE.** The stalk of the ovary, within the origin of the calyx.

**GYNOPLEURA.** A genus of Chilian herbs, with entire or lobed leaves, and yellow flowers in terminal clusters or tufts. They belong to the *Malosherbiaceæ*, and are known by their bell-shaped calyx, five petals inserted outside an annular membranous slightly toothed corona, which is attached to the throat of the calyx; and five stamens, inserted at the base of a short stalk that supports the one-celled ovary. [M. T. M.]

**GYNOSTEMIUM.** The column of orchids; that is to say, the part formed by the union of stamens, style, and stigma.

**GYNOSTEMMA.** A genus of *Cucurbitaceæ*, of tropical and subtropical Asia, having entire or lobed leaves, panicle unisexual flowers, a two-ranked calyx, no corolla, five monadelphous stamens, and a half-inferior ovary. Fruit succulent, with three or four one-seeded stones. [M. T. M.]

**GYNOXIS.** A genus of composite plants confined to America, and there found from Guatemala southward to Peru. They are nearly related to *Senecio*, and chiefly differ in the style-branches being prolonged into conical in-pid points, instead of being obtuse. Some are trailing bushes with alternate lance-shaped or ovate leaves; and the yellow flower-heads few and large,

or numerous small and arranged in corymba. Another and larger group, which is restricted to the Andean regions of Ecuador and New Grenada, are erect opposite-leaved bushes or small trees, with white or yellow rayed or rayless flower-heads, resembling those of our own groundseils. This latter group M. Weddell keeps alone in the genus, and places the former with true groundseils. To the latter belongs *G. fragrans*, the only species known in cultivation, a scandent bush with somewhat fleshy ovate leaves, and pale yellow fragrant flowers, the heads about an inch across and disposed in loose corymba at the ends of the twigs. About twenty species are enumerated. [A. A. B.]

**GYNUA.** A genus of the compositae family, containing upwards of twenty species, all found in the tropics of the eastern hemisphere, occurring in greatest numbers in India and its Archipelago. From *Senecio*, to which it is closely allied, it differs in the style-branches having long protruding points. Many of the species are coarse perennial weeds, with distantly toothed or pinnatifid leaves, the angular stems terminating in corymba of rich yellow flower-heads, whose florets are all tubular. Other species are scrambling undershrubs. The rootstocks in some are thick and fleshy, and not unfrequently the leaves are of a fine purple colour underneath, which is the case with the *G. bicolor*, a species from the Moluccas, cultivated in hothouses for the sake of its leaves, and having rich orange-coloured flower-heads disposed in loose corymba. [A. A. B.]

**GYPSOCALLIS.** *Erica*.

**GYPSOPHILA.** A genus of annual or perennial evergreen herbaceous plants belonging to the *Caryophyllaceae*, in the alsinaceous division of which they are distinguished by having the calyx campanulate, angular, somewhat five-lobed, the margins membranous; five petals without claws; ten stamens; two styles; and a one-celled capsule. The species, which are numerous, have leaves like those of the pink, and small white or pink flowers, which are usually disposed in diffuse panicles. They inhabit various parts of Europe and Asia, growing mostly in rocky or stony places, especially in a limestone soil. Some of them are occasionally cultivated as border plants, or on rockeries. [C. A. J.]

**GYRANDRA.** A Mexican perennial with the habit of a *Chironia*, and forming a genus of *Gentianaceae*. The flowers have a five-parted wheel-shaped purple corolla, into the throat of which are inserted the stamens, whose showy yellow twisted anthers give a distinguishing character and name to the genus. [M. T. M.]

**GYRATE.** The same as *Circinate*; curled inwards like a crotcher.

**GYRINOPSIS.** An aquilariaceous shrub of the Philippine Islands. The perianth is coloured and funnel-shaped, with a five-cleft

limb; and there are ten short hairy scales placed in pairs opposite the lobes of the perianth. [M. T. M.]

**GYROCARPUS.** A genus of apetalous *Exogena*, consisting of trees having polygamous flowers, natives of the East Indies and tropical parts of America. The leaves are alternate, undivided or lobed, and the flowers are collected in dense panicles. The calyx in the hermaphrodite flowers is superior, and four to eight-lobed; the stamens four, with glands interposed, and the anthers remarkable for opening by valves which turn upwards. The ovary, which is completely adherent to the tube of the calyx, is one-celled with one pendulous ovule, the style slender, and the stigma obtuse. The fruit is nut-like, two-winged at the apex, from two of the lobes of the calyx enlarging while the others fall off. The male flowers have the same lobed calyx and stamens as the hermaphrodite. This genus is very near *Illigera*, from which it differs in its fruit being winged at the apex, not on the sides, and in common with it is nearly allied to *Lauraceae* and *Combretaceae*, with the latter of which families it has been combined. It is sometimes considered as the type of a distinct family, and separated under the name of *Gyrocarpeae*. See also *ILLIGERA*. [B. C.]

**GYROMA, or GYRUS.** The ring or articulated circle which surrounds the apothecases of ferns; also a button-like shield, such as is found among lichens in the genus *Gyrophora*.

**GYROPHORA.** A genus of lichens belonging to the order *Pyxizet*, distinguished by its curiously convoluted fruit, a number of disks being produced in a proliferous manner within the original fruit. The species grow on rocks and large boulders, and are remarkable as supplying the Tripe de Roche of the Arctic voyagers, so called from the bullate dilated frond. The bitter principle is so strong in these plants, that, though they have considerable nutritive qualities, they do not agree as an article of food with many constitutions. *Umbilicaria*, which is distinguished by the more simple disks, supplies also a part of the Tripe, which is collected without much discrimination of species. [M. J. B.]

**GYROSE.** Bent backwards and forwards as the anthers of cucurbits.

**GYROSELLE.** (Fr.) *Dodecatheon*.

**GYROSTEMON.** A genus of *Phytolaccaceae*, consisting of small branched shrubs from South-western Australia with alternate linear semi-cylindrical mucronate leaves, and solitary axillary stalked dioecious flowers, with a six or seven-lobed calyx; the males have numerous stamens, in several rows, the females many carpels placed round a thick central axis. The fruit is obovate, of many membranaceous cocci, in a single row. This latter character distinguishes it from *Odonocarpus*, which has the cocci arranged in more than one row. [J. T. B.]

**HAAGEA.** A genus of *Begoniaceae*, called after Haage, an Erfurt horticulturist. The flowers are rose-coloured, monocious, with two perianth leaves; the staminate ones with numerous stamens; and the pistillate ones with an inferior three-celled equally three-winged ovary, a three-parted smooth persistent style, and broadly expanded stigmas, surrounded by a papillose band twisted once spirally. The only species, *H. dipetala*, a shrub with semicordate petiolate leaves, and pendulous floral cymes, native of the East Indies, was formerly called *Begonia dipetala*. [J. H. B.]

**HABEL-ASSIS.** (Fr.) *Cyperus esculentus*.

**HABENARIA.** A well-known extensive genus of terrestrial tuberous-rooted orchids, more or less generally distributed, though most numerous in India and Africa. It is represented in Britain by *H. viridis*, *H. bifolia*, and *H. chlorantha*, the first known as the Frog Orchid, the two last as the Butterfly Orchid. These two are very similar, having a stem a foot high or more, with two oblong obtuse leaves at the base, above that a few narrow green bracts, and then an erect terminal spike of very fragrant long-spurred white flowers. The difference between the two is, that in *H. chlorantha* the flowers are larger, the throat or the nectary or spur much wider, and the two pollen-masses more distant from each other. For a most interesting account of the mode of fertilisation in these two plants, see Mr. Darwin's book, *On the Fertilisation of Orchids*. Some of the Indian species are notable for the length of spur, as in the appropriately named *H. longecalcarata*, where, with flowers an inch across, the spur is four inches in length. The habit of most of the species is similar to that of our native *Orchis*, to which they are closely related, differing chiefly in the two glands of the pollen-masses being inserted into separate pouches instead of into a common one. The flowers vary much in colour, some being green, others rose, a goodly number golden yellow, but the greater part white, and usually very fragrant. [A. A. B.]

**HABINE.** (Fr.) *Dolichos melanophthalmus*.

**HABIT.** The general appearance of a plant; its manner of growth, without reference to details of structure.

**HABITAT.** The situation in which a plant grows in a wild state.

**HABITZIA.** A perennial Caucasian twining herb, of the order *Amaranthaceae*, with a turnip-shaped root and furrowed stem, large alternate long-stalked glabrous cordate-acuminate entire leaves, and flowers in small cymes collected into dense axillary panicles; the perigone green and five-cleft, the stamens five. [J. T. S.]

**HABRACANTHUS.** A genus of *Acanthaceae*, containing three species from Mexico, herbs or shrubs with oblong or

oval leaves, and white or red flowers in terminal panicles or in few-flowered axillary cymes. The calyx is deeply five-parted, and the corolla ringent, with the upper lip falcate and entire, and the lower three-parted; there are two exserted diverging stamens, and the ovary is surrounded by a broad disk at the base, has four ovules near the middle, and is surmounted by an acute stigma. [W. G.]

**HABRANTHUS.** A genus of hippeastriform *Amaryllidaceae*, distinguished in that group, which has a narrow-mouthed perianth tube, by the perianth being decinate, but not convolute into a tube-like form as in the allied *Phycella*, and by the faucal membrane being annular. They consist of handsome South American bulbs, found principally in Chili, Monte Video, and Buenos Ayres. The plants have narrow two-ranked sacrid leaves, and a precocious scape which either is single-flowered or bears an umbel of few or many flowers of a crimson, scarlet, rose, purple, whitish, yellow, or red and yellow colour. The perianth is subcinchonate with a short tube, the limb more or less spreading, the stamens unequal inserted at the mouth of the tube, the faucal membrane annular, and the stigma three-lobed. [T. M.]

**HABROTHAMNUS.** A genus of beautiful Mexican shrubs, belonging to the *Solanaceae*. The flowers have a bell-shaped five-toothed calyx, a club-shaped tubular corolla, with the limb contracted and five-toothed; five stamens concealed within the corolla; and a button-shaped stigma. The fruit is succulent, surrounded by the calyx, two-celled, each cell containing a few seeds. The panicles of red or purple flowers are borne in abundance, and justify the name applied to them—which signifies graceful branch. [M. T. M.]

**HABROZIA.** A genus of *Scleranthaceae*, differing from the rest of the order in having the utricle adhering to the seed, and the calyx tube not constricted at the throat. It is a small annual oriental herb, with slender stems, setaceous leaves, and many-flowered terminal cymes. [J. T. S.]

**HABZELIA.** A small genus of *Anonaceae*, now united with *Xylopia*, having a wide geographical distribution, two species being found in Malaya, one in Upper Guinea, and the remainder in Guiana and Cuba. It belongs to the *Xylopiaceae*, and is distinguished from its allies by the torus being flat, instead of drawn up into a cone or hollowed out. The flowers are three-sided, having three sepals joined together at the bottom, and six petals arranged in two series, the inner ones being rather smaller than the outer. The fruit consists of numerous long nearly cylindrical pods, separate from each other, and containing a number of oblong seeds. The plants are either tall shrubs or trees about twenty or thirty feet high, and have long simple leaves of a leathery texture, from the base of which the flowers are produced either singly or in clusters. *H. ethiopica*,

a tall shrub, with pointed egg-shaped leaves, covered with whitish down underneath, but smooth and green above, is a native of Western Africa, where its fruit, which consists of a number of smooth pod-like carpels about the thickness of a quill, and two inches long, is dried and used instead of pepper, whence it is often called Negro-pepper, Guinea pepper, or Ethiopian pepper, and by old authors *Piper aethiopicum*. The fruits of *H. undulata* are used in the same way, as also are those of *H. aromatica*: indeed, it is probable that the fruits of all the species possess similar aromatic and pungent properties. [A. S.]

**HACKBERRY.** *Celtis crassifolia*; also *C. occidentalis*.

**HACKMATAK.** The American Larch, *Abies pendula*.

**HACQUETIA.** A genus of umbellifers, distinguished by having the limb of the calyx leaf-like and persistent, forming a crown to the fruit, which is contracted at the sides, each half having five narrow ribs. The genus was named in honour of Hacquet, who published an account of the Alpine plants of Carniola. *H. Epipactis*, the only species, is a small herbaceous perennial plant resembling an *Astrantia*, having digitate three-lobed leaves, and a single umbel of yellow flowers. [G. D.]

**HADSCHY.** The narcotic Hashish, *Cannabis sativa*.

**HÆMADICTYON.** A genus of dogbanes, distinguished by the border of the corolla having five equal broad bent lobes, its tube having on its inside five small scales alternate with the lobes; the style ending in a head-like summit; and by five small glands being situate at the base of the seed-vessel, alternate with the divisions of the calyx. The name is from the Greek, and indicates the crimson tint of the leaf-veins. The species are climbing sarubs, natives of tropical America. [G. D.]

**HÆMANTHUS.** A genus of *Amaryllidaceæ*, consisting for the most part of South African bulbs, some few species being found in tropical Africa. It belongs to the amaryllidiform group, that with a solid scape, and the stamens not connected by a cup. The special characteristics are a regular perianth with straight tube, and a valveless fruit with a pulpaceous middle coat. The species are rather numerous. They have tunicated bulbs with the scales often two-ranked, and few leaves, often only two, which are thickish and plane, erect or lying flat on the ground. The scape is short, often with a pair of bracts at the base, sometimes coloured and terminating in an umbel of many crowded flowers, usually with a many-leaved spathe, the leaflets of which are erect, often coloured, and longer than the flowers. The flowers are red or white, sometimes very showy. The perianth is six-cleft with erect or spreading segments, and a short tube; the stamens six, exserted; the style filiform, with a simple or obsoletely three-lobed

stigma; and the ovary three-celled, becoming a globose or oblong berry. [T. M.]

**HÆMARIA discolor**, or, as it has been called, *Goodyera discolor*, is a small herbageous orchid of South China, having creeping succulent stems throwing out roots at intervals, bearing towards the apex a few ovate leaves, and ending in an erect flower-spike a few inches in length furnished with a number of crimson bracts. The leaves are nearly three inches long, green above, and crimson underneath; and the flowers are white and three-quarters of an inch across. The plant has altogether the appearance of a *Goodyera*, and differs chiefly from that genus in the sepals being like the petals and not herbaceous. It is cultivated in gardens for the sake of its beautiful leaves. [A. A. B.]

**HÆMATITICUS.** Dull red, with a slight mixture of brown.

**HÆMATOCOCCUS.** A genus of chloro-sperms, in which, however, some of the species have red, and some green spores, and probably for this reason the word *Gloeocapsa* has been substituted for it. The plants consist of a shapeless gelatinous mass made up of vesicles containing a variable number of spores which propagate the plant by cell-division, new cells being formed from the divided spores within the mother cell. The species are numerous, and are important as illustrating under a simple form the great principle of increase by cell-division. The individual plants closely resemble the gonidia of *Ephra*. Some of the species are, it is believed, merely an early stage of certain lichens. [M. J. B.]

**HÆMATORCHIS.** *Cyrtostia*.

**HÆMATOSTAPHIS.** A small glabrous tree from tropical Africa, with pinnate leaves and long axillary panicles of small white flowers, forming a genus of *Anacardiaceæ*, allied to *Odina*, *Schinus*, &c., but differing from all in its trimerous irregular flowers, and in habit. The drupes of a deep crimson, collected in bunches resembling grapes, are eatable, and although acid are not unpleasant.

**HÆMATOXYLON.** The tree yielding the well-known Logwood of commerce is the sole representative of this genus of *Leguminosæ Cæsalpinia*. It is a native of the Bay of Campechy in Yucatan—whence it is named *H. campechianum*—and also of other parts of Central America, and has been introduced into, and is now naturalised in, many of the West Indian islands. The tree is one of medium size, seldom exceeding forty feet in height, with a trunk about a foot and a half in diameter, and having its smaller branches covered with white bark, often spiny. The leaves are pinnate, consisting of from three to four pairs of small smooth obversely egg-shaped leaflets; and the yellow flowers are produced in racemes from the bases of the leaves. The pod is flat, tapered to both ends, and contains two seeds, but

instead of splitting open along the edges, as many other pods do when ripe, its thin sides burst irregularly and allow the escape of the seeds.

Logwood, the produce of this tree, was one of the valuable commodities introduced into Europe by the Spaniards, during the early part of the century following the discovery of America by Columbus. Its use in England dates from the time of Queen Elizabeth, but the dyers of that period were so little acquainted with the chemical principles involved in the art of dyeing, that they failed to render its colours sufficiently permanent, and the prejudice against it consequently became so strong, that, in the twenty-third year of Elizabeth's reign, an act of parliament was

*Hematoxylon campechianum.*

passed prohibiting its use, and ordering it to be burned wherever found within the realm; and although it was subsequently surreptitiously introduced under the name of Black-wood, this law was not repealed until the time of Charles II., nearly a century afterwards. At the present day it is largely employed by calico-printers and cloth-dyers, and also by hat-makers, who use it, in combination with indigo and certain mordants, for imparting the fine black to silk hats. It likewise forms an ingredient in some of the commoner descriptions of writing-ink. Its properties depend upon the presence of a colouring principle termed *hematoxylin* or *hæmatusin* by Chevreul.

Logwood occurs in commerce in logs about three feet long, and consists of the heart-wood of the tree, from which the sap-wood, which is light-coloured and valueless, has been removed. It is of a deep dull brownish-red colour, and very hard and heavy; and, for the convenience of dyers, it is cut into chips by means of powerful machinery. Our imports in 1860 amounted to 26,938 tons, the greater and most valued portion of which was the produce of Cen-

tral America; the remainder being from the West Indian Islands.

**HÆMODORACEÆ.** (*Vellozia*, *Blood-root*.) A natural order of epigynous monocotyledons belonging to Lindley's narcissal alliance of *Endogæna*. Perennial plants with fibrous roots, and a sword-shaped equitant leaves, and bearing woolly hairs or scurf on their stems and flowers. Perianth tubular, six-divided; stamens three, placed opposite the segments of the perianth, or six; anthers introrse. Ovary three-celled, sometimes one-celled; style and stigma simple. Fruit usually capsular, opening by valves, covered by the withered perianth; embryo in cartilaginous albumen. Natives of America, the Cape, and New Holland. The roots of some of the plants yield a red colour—hence the name of the order. Bitterness exists in some of them. There are about a dozen genera, and fifty species. Examples: *Hæmodorum*, *Aletris*, *Vellozia*, *Barbaccina*. [J. H. B.]

**HÆMODORUM.** A genus of *Hæmodoraceæ*, consisting of perennial glabrous Australian herbs, having fasciculate tubers, simple leafy stems, with half-sheathing plane or somewhat terete averse leaves, and corymbs or branched spikes of flowers, the perianth of which has a tube connate with the base of the ovary, and a limb of six narrow persistent segments, three stamens, and a three-celled ovary with filiform style and simple stigma. [T. M.]

**HAGBERRY.** *Cerasus Padus*; also *Celtis crassifolia*.

**HAIMARADA.** *Vandellia diffusa*.

**HAIR, AFRICAN.** The fibre of the leaves of the Palmetto, *Chamærops humilis*.

**HAIRBELL.** *Campanula rotundifolia*.

**HAIR-BRANCH TREE.** *Trichocladus crinitus*.

**HAIR-POINTED.** Terminating in a very fine weak point.

**HAIR-SHAPED.** The same as Filiform, but more slender, so as to resemble a hair; it is often applied to the fine ramifications of the inflorescence of grasses.

**HAIRS.** Small delicate transparent conical expansions of the epidermis, consisting of one or more cells.

**HAIRY.** Covered with short weak thin hairs.

**HAIR-TRIGGER FLOWER.** *Stylidium grammifolium*.

**HAI-TSAI.** A transparent gluten much used in China; the chief ingredient is supposed to be *Plocaria tenax*, a small seaweed.

**HAKEA.** A large proteaceous genus containing above one hundred species. It is distinguished by having a calyx irregularly four-cleft or with four linear or spatulate sepals, each lobe or sepal bearing on its concave apex an ovate sessile anther; a filiform style, and terminal or

oblique stigma; and a one-celled seed-vessel (follicle), which is generally woody, ovate or oblong and swollen, rarely globose, smooth or tuberculated, and often with two spurs. The foliage is extremely variable: in *H. acicularia*, *propinqua*, *pugioniformis*, *longicuspis*, *Cunninghamii*, *lorea*, &c., it is simple, filiform, occasionally furrowed, and the points mostly very sharp, the leaves in the last-named species being from eighteen inches to two feet in length; in *H. lasiocarpa*, *trifurcata*, &c., it is very narrow and flat; in *H. linearis*, *florida*, *ilicifolia*, *prostrata*, &c., it is linear-lanceolate or ovate, with more or less spiny margins; in *H. cucullata*, *conchifolia*, and *Victoria*, it is broadly heart-shaped, with toothed margins; in *H. arborescens*, *Leucadendron*, *pandanicarpa*, *dactyloides*, &c., it is linear-spathulate and of a very leathery texture. The fruit of *H. pandanicarpa* is very large, and covered with conical tubercles. The leaves in *H. mimosoides*, *saligna*, *oleifolia*, &c., are either lanceolate or ovate. The genus consists generally of tall shrubs, or occasionally of small trees, as *H. lorea*, *Preissii*, *arborescens*, &c. Some of the species have been found in every portion of Australia and Tasmania that has yet been visited. [R. H.]

**HALBERD-WEED.** *Neurolema*.

**HALBERT-HEADED.** Abruptly enlarged at the base into two diverging lobes, like the head of a halbert.

**HALEDSCH.** *Balanites aegyptiaca*.

**HALENIA.** A genus of Siberian herbaceous plants of the gentian family. Their flowers have a four-parted calyx; a four-cleft corolla whose segments are prolonged at the base into a spur; four stamens; and a one-celled ovary with a two-lobed stigma. *H. heterantha* is remarkable from its lower flowers having no spurs, while the upper ones are provided with them. [M. T. M.]

**HALESIACEÆ.** One of the names of the order *Styracaceæ*.

**HALESIA.** A genus of *Styracaceæ*, differing from the others in its two to four-winged fruits, which are one to two inches long, with a bony one to four-celled kernel. The Snowdrop or Silver-bell trees, as the species are commonly called, are natives of the United States. They are deciduous shrubs or small trees with alternate stalked ovate-oblong toothed leaves, an inch or two long when the plant is in flower, but much larger when mature. The flowers bear much resemblance to snowdrops, and are supported on slender drooping stalks, two or three together, arising from the buds of the preceding year. A tree about thirty feet high of *H. tetraptera* formerly stood in the Arboretum in Kew Gardens, flowering in May and June. The genus bears the name of Dr. Stephen Hales. [A. A. B.]

**HALF.** Sometimes used in the sense of one-sided; as *half-cordate*, which signifies cordate on one side only. — **MONOPETALOUS.** Having the petals united, but so

slightly that they easily separate. — **NETTED.** When of several layers of anything, the outer one only is netted; as in the roots of *Gladiolus communis*. — **STEM-CLASPING.** Claspings the base in a small degree. — **TERETE.** A long narrow body, flat on one side, convex on the other.

**HALVED.** When the inequality of the two sides of an organ is so great that one half of the figure is either wholly or nearly wanting, as the leaf of many *Begonias*.

**HALIANTHE.** (Fr.) *Arenaria peploides*.

**HALIDRYS.** A generic name given to the old *Fucus siliquosus*, which is a frequent inhabitant of our coasts, and distinguished at once from all other native *Algæ* by the pod-like jointed air-bladders. The only other representative of the genus, *H. osmundacea*, is found on the north-west coast of America. [M. J. B.]

**HALIMEDA.** A genus of calcareous green-spored *Algæ*, with the habit of the Indian fig, belonging to the natural order *Siphonææ*. The frond is composed, like *Caulerpa*, of a branched thread which traverses every part of the plant, but never has any articulations. The endochrome is at length resolved into minute zoospores. The species are all inhabitants of warm seas. *H. Opuntia* is widely diffused, and is found in the Atlantic and Pacific oceans, and also in the Mediterranean and Red seas. The plants grow in sand or amongst fragments of shells, being attached by a mass of fine thread-like roots, which grasp the particles of sand &c., and form a little ball. [M. J. B.]

**HALIMUS.** A group of *Thenopodiaceæ*, allied to *Atriplex*, but now sunk under the genus *Oblonia*; it is, however, retained as a section of the latter, distinguished by having the perigone surrounding the fruit closed, and joined by the whole length of their sidea. *Oblonia pedunculata*, an annual, found, though rarely, in salt marshes in the south-east of England, belongs to this section; it has alternate obovate or oblong slightly fleshy leaves, with a mealy covering, and axillary glomerules of small flowers arranged in interrupted spikes. The fruit is remarkable from the pedunculated obcordate fruiting bracts. [J. T. S.]

**HALLERIA.** A genus of *Scrophulariaceæ*, consisting of erect glabrous shrubs, with opposite ovate evergreen leaves, and showy scarlet flowers, solitary or clustered in the upper axilla. The shape of the corolla is nearly that of a *Penstemon*, but the calyx is broad and cup-shaped; there is no rudimentary fifth stamen, and the fruit is a berry. There are three species known, all natives of the Cape Colony in South Africa.

**HALLIA.** A genus of *Lepurminææ* peculiar to South Africa, consisting of a few erect or decumbent perennial herbs, with slender angled or winged stems, simple heart-shaped or lance-shaped leaves, and in their axilla solitary or twin stalked flowers, nearly the size of those of a vetch,

and violet-coloured. The genus is most nearly related to *Alhagi*; but they are spiny erect bushes, with more than one seed to the pod, while here the habit is very different, and the minute compressed pods have but one seed. Linnaeus named the genus after Berger Martin Hall, one of his pupils. [A. A. B.]

**HALOCNEMUM.** A genus of *Chenopodiaceae*, allied to *Salicornia*, but having the perigone of three scale-like leaves, not monophyllous. They are small leafless jointed-stemmed plants, with the flowers collected into terminal spikes, much as in *Salicornia*. They occur chiefly in Southern Russia, Siberia, &c. [J. T. S.]

**HALODENDRON SATINÉ.** (Fr.) *Haltmodendron argenteum*.

**HALODULE.** A genus of *Naiadaceae* allied to *Zannichellia*, of which it has the habit, but with diœcious flowers; the leaves resemble those of *Zostera* in miniature. The plant grows in estuaries in Madagascar. [J. T. S.]

**HALOGETON.** A genus of *Chenopodiaceae* allied to *Salsola*, but having the seed vertical instead of horizontal. They are herbs or small shrubs found in Southern Russia, Siberia, Persia, &c., with alternate or opposite fleshy sculi-cylindrical leaves, and axillary glomerules of flowers, of which the perigone is furnished with transverse wings when in fruit. The seeds of *H. tamariactifolium*, a Spanish species, are called Spanish Wormseed from their anthelmintic properties. [J. T. S.]

**HALOPHILA.** A genus of small herbaceous plants growing in salt marshes in Madagascar and elsewhere, usually referred to the *Podostemaceae*, but excluded by Tulasne in his elaborate treatise on that order. They are plants of little general interest, having unisexual flowers, with a two-leaved perianth, and three stamens; and in the female ones, a stalked one-celled ovary. [M. T. M.]

**HALORAGACEÆ.** (*Haloragaceae*, *Hippurideae*, *Cercodiaceae*, *Hydrocaryaceae*, *Hippurideae*.) A natural order of calycifloral dicotyledons, belonging to Lindley's myrtal alliance of epigynous Exogens. Herbs or undershrubs, often aquatic, with alternate opposite or whorled leaves, and small frequently incomplete flowers. Calyx adherent, with a minute limb; petals inserted into the upper part of the calyx, or absent; stamens attached to the calyx; ovary with one or more cells; ovules pendulous anastropal. Fruit dry, not opening; seeds solitary, pendulous. The plants may be regarded as an imperfect form of *Onagraceae*. They are found in damp places, ditches, and slow streams, sometimes submerged, in all parts of the world. [Bentham and Hooker, in their *Genera Plantarum*, include the order *Gunneraceae*, represented by *Gunnera*, and also the genus *Callitriche*, a very anomalous genus which some botanists regard as forming a distinct natural order.] *Hippuris*

*vulgaris* is the common mare's tail of our ponds. There are about ten genera and eighty species. Examples: *Hippuris*, *Myriophyllum*, *Haloragis*, *Loudonia*, *Gunnera*. [J. H. B.]

**HALORAGIS.** A genus of *Haloragaceae*, differing from the greater number of plants of this order, in not being aquatic. They occur in tropical Asia, and more abundantly in Australia and New Zealand. Their lower leaves are opposite, the upper often alternate; and the flowers are axillary, solitary or aggregated, combined into spikes, racemes, or even panicles. *H. citriodora*, the Piri-iri of the New Zealanders, has scented leaves. [J. T. S.]

**HAMADRYAS.** A genus of *Ranunculaceae* from the Antarctic regions. More or less silky herbs, with palmately-parted or undivided leaves, and scapes with one to three flowers, the calyx and corolla externally hairy, the former with five or six sepals, the latter with ten or twelve long linear subulate petals. The flowers are diœcious by abortion, and the female ones have an ovate globose head of pistils terminated by hooked styles. [J. T. S.]

**HAMAMELIDACEÆ.** (*Witch Hazels*.) A natural order of calycifloral dicotyledons, belonging to Lindley's umbellal alliance of epigynous Exogens. Trees or shrubs with alternate feather-veined leaves having deciduous stipules. Calyx four to five-divided; petals four, five, or wanting; stamens eight, the anthers introrse; ovary two-celled, inferior; ovules solitary or several; styles two. Fruit two-valved; seeds pendulous, albuminous. In some of the plants there are circular disk-like markings in the woody tubes. Natives of North America, Asia, and Africa. There are seventeen known genera, including *Hamamelis*, *Rhodoletia*, and *Bucklandia*. [J. H. B.]

**HAMAMELIS.** A genus of the witch-hazel order, distinguished by its calyx being four-parted; the corolla of four petals; the stamens four, alternate with the petals, and having four-scale-like bodies—rudimentary stamens—opposite the petals. The name was adopted from a Greek term used to indicate resemblance to an apple tree, a comparison which is scarcely applicable. The species are shrubs of North America and China, with alternate leaves, and usually yellow flowers. *H. virginica* has been long known in cultivation. It has obovate toothed leaves, and is widely diffused in North America, attaining a height of ten or twelve feet, its yellow flowers appearing in the fall of the year, and its fruit ripening in spring. Its seeds contain a quantity of oil, and are edible; while the leaves and bark are astringent. It is employed as a remedy in various ways by the aborigines. [G. D.]

**HAMATO-SERRATE.** When serratures have a somewhat hooked form.

**HAMELIA.** Tropical American shrubs, forming a genus of *Cinchonaceae*, named in honour of M. du Hamel, a noted French vegetable physiologist. The flowers are

orange-coloured and tubular; stamens five, concealed within the corolla; ovary five-celled, surmounted by an epigynous disk; style simple; stigma undivided; fruit succulent, five-celled, with numerous seeds in each compartment. *H. patens* and other species are in cultivation as stove plants, and have handsome flowers. [M. T. M.]

**HAMELINIA.** A genus founded by Richard on imperfect female specimens of *Asclella Banksii* or *Solandria*, and consequently not adopted by other botanists who have had better opportunities of examining these species. [J. T. S.]

**HAMI** (adj). **HAMATE, HAMOSE.** Hooks, hairs, or small spines which are hooked at the point.

**HAMILTONIA.** Indian shrubs with fragrant flowers, constituting a genus of *Cinchonaceae*. The flowers have a funnel-shaped corolla with a long tube and a limb divided into five oblong lobes; stamens five, concealed within the tube of the corolla; ovary inferior, five-celled; style simple; stigma with five acute segments; capsule one-celled, with five one-seeded stones. *H. aureolens* and *H. scabra* are cultivated in stoves, for the sake of their white fragrant flowers. [M. T. M.]

**HAMMERSEGE.** *Carica hirta*.

**HAMPEA.** A genus of the *Bombac* family peculiar in the nature of its fruits, which are rusty-coloured capsules of the size of a cherry, bursting into two or three portions, each portion containing a single seed with a fleshy aril at its base. There are but two species, one a Mexican bush, the other a tree of New Grenada. Both have alternate long-stalked leaves, like those of the common poplar but larger; and bear on the same tree sterile and fertile white flowers, about half an inch across, solitary or two to three together in the axils of the leaves. They have a bell-shaped calyx with an entire border, five narrow petals slightly united at the base, and numerous stamens of unequal length; or, in the fertile flowers, a few barren stamens united into a ring inserted on the base of the petals, and surrounding the ovary. [A. A. B.]

**HAMULOSE.** Covered with little hooks.

**HAMULUS.** A kind of hooked bristle found in the flower of *Uncinia*. Schleiden regards it as a third glume, free from the two which form the flask.

**HANBURYA mexicana** is the sole representative of a genus of *Cucurbitaceae* peculiar to the mountains near Cordoba, Mexico, and named after Daniel Hanbury, a distinguished London pharmacologist. It is a climber, having a pentagonal stem, furnished with simple tendrils, cordate leaves, axillary or terminal white and monocious flowers, the males being arranged in racemes, whilst the females are solitary in the axils of the leaves. The calyx and corolla are bell-shaped; the ovary is four-celled, each cell containing

one seed; and the fruit is oval, covered with long spines, and bursting open like that of *Momordica*, propelling the flat circular seeds (resembling those of *Fenillea*) to some distance. The Mexican squirrels are fond of eating the seeds, but, being unable to open a fruit so well protected by spines, they wait in the morning for the time when the first rays of the sun fall upon the ripe ones and cause them to burst. The Mexicans term the plant Chayotilla, from the close resemblance of its fruit to that of the cayotl or chayota (*Sechium edule*). [B. S.]

**HANCHINOL.** The Mexican name for *Hennipia salicifolia*.

**HANCORNIA.** A small genus of *Apocynaceae*, found in Brazil, and forming small trees or shrubs, abounding in all parts with a viscid milky juice, which is one of the sources of caoutchouc. They have entire opposite leaves, marked with pellucid veins; and sweet-smelling flowers resembling those of the jasmine. The calyx is five-parted, without glands; the corolla has a long narrow tube, hairy inside, and the five segments spread out when the flower opens, but are previously rolled round each other; the five stamens are inserted into the middle of the tube; and the ovary is divided into two cells, and has a long thread-like smooth style, and a forked stigma. The fruit is a large globular or pear-shaped fleshy berry, exuding a milky juice when wounded, and containing numerous hard seeds lying in pulp.

*H. speciosa* is a small tree somewhat resembling the weeping-birch in habit, with drooping branches, and small oblong leaves, sharp at the base, and rounded but with a short point at the apex. It is called Mangaba or Mangava, and bears a most delicious fruit, which is a great favourite with the Brazilians, but is only fit to eat when perfectly ripe, or after being kept for a short time. It is about the size of a plum, of a yellow colour marked with red spots or streaks. The milky juice of the tree, when exposed to the air, hardens into a kind of caoutchouc. [A. S.]

**HAND-PLANT.** *Cheirontemon platynoides*.

**HANNEBANNE.** (Fr.) *Hyoscyamus niger*.

**HANNOA.** The name of a Senegambian tree, forming a genus of *Simarubaceae*. The flowers are unisexual, the males with the sepals combined into a somewhat two-lipped calyx, and the rudimentary ovaries concealed within a large disk. The female flowers are not known. [M. T. M.]

**HAPLANTHUS.** A genus of *Acanthaceae*, containing three species, natives of India. They are erect branching herbs, with ovate petiolate leaves, and flowers in few-flowered terminal racemes furnished with small bracts. The calyx is five-parted, the corolla funnel-shaped, with an unequally five-cleft limb; the two stamens

are included; and the capsule is linear and flattened, with several seeds. [W. O.]

**HAPLODESMIUM.** A genus of *Melastomaceæ*, consisting of a shrubby branching small-leaved plant, with elliptical leaves and tetramerous flowers. The calyx is campanulate, its teeth nearly equalling the tube; the petals oblong-ovate, blunt; the stamens eight equal; and the ovary free, four-celled. The fruit is a four-valved capsule crowned by the persistent teeth of the calyx. *H. Lindenianum*, a native of the Andes about Truxillo, grows at an elevation of from 4,000 to 12,000 feet. [J. H. B.]

**HAPLOLENEÆ.** A tribe of frondose *Jungermanniaceæ*, characterised by a one-leaved involucre without any true perianth (the sheathing tube being merely the veil), a spherical capsule, and dichotomous ribbed fronds. Sometimes the rib is confluent with the margin. This tribe contains some of the finest of the frondose liverworts, vying with the smaller *Hymenophylla* in beauty and delicacy of frond (see *SYMPHYOGYNA*). *Pellia epiphylla* is a well-known British representative. [M. J. B.]

**HAPLOPAPPUS.** An American genus of *Compositæ*, distinguished from its allies in the *Solidagineæ* by the oblong or top-shaped more or less silky achenes being crowned with a pappus of rigid (not capillary) bristles. Some are North American, but the greater number are Chilean, and some of them inhabit the high Andean regions. They are mostly perennials, with alternate lance-shaped or oblong leaves, and twigs terminated by yellow-rayed flower-heads, though in some the heads are without rays. A few are nearly stemless, with leaves like those of the daisy but sharply toothed, while others have pinnatifid downy leaves. A shrubby Chilean species, *H. Baylahuen*, with glutinous stems, and spatulate unequally-toothed leaves embracing the stem by their narrowed base, is used by the Chileans, according to M. Gay, in the treatment of various diseases in their domestic animals, and is called by them Baylahuen. [A. A. B.]

**HAPLOPHLEBIA.** *Alaphila*.

**HAPLOPETALUM.** A genus of *Legnoidææ*, which tribe Mr. Benthams refers to the order *Rhizophoraceæ*. The genus is thus characterised:—Calyx four-parted; petals four entire; stamens four or five times as numerous as the petals, inserted on the margin of a very short disk; lower part of the ovary, which alone contains the ovules, adherent to the calyx, the upper part detached. The species is a Fee-jean plant. [M. T. M.]

**HAPLOPHYLLUM.** A genus of perennial plants or undershrubs, natives of Southern Europe &c., and distinguished from *Ruta* by their simple leaves, and five to six-parted flowers, the filaments hairy on their inner surface, and the style thick towards the top. [M. T. M.]

**HAPLOPTERIS.** A genus of polypodiaceous ferns of the group *Pteridææ*, having simple coriaceous fasciculate fronds, on which the sori are linear continuous and marginal, with a broad firm marginal inflexed indusium opening along the inner edge. The veins are simple from a central costa. *H. scolopendrina*, the only species, a native of Bourbon, has quite the aspect of a broad-fronded species of *Vittaria* or *Taniopsis*. [T. M.]

**HAPLOSCIADIUM.** An Abyssinian umbellifer with radical twice-plumated leaves, like those of a *Meum*, and simple umbels on simple or scarcely branched scapes. It was supposed to constitute a distinct genus, but is united by Benthams and Hooker with *Trachydium*.

**HAPLOSTEMMA.** A name proposed by Endlicher to receive a plant which Desrousse has referred to *Vincetoxicum*, from which it does not differ materially. [W. O.]

**HAPLOSTYLUS.** *Rhynchospora*.

**HAPLOTAXIS.** The same as *Aplotaxis*.

**HARDENBERGIA.** A genus of *Leguminosæ* found in Southern and Western Australia, and consisting of a few slender woody climbers, very similar in appearance, and all desirable as greenhouse plants from the profusion of their flowers. They are most nearly related to *Kennedyæ*, from which they are readily distinguished by their flowers being small and numerous, arranged in stalked racemes, instead of few and nearly as large as those of a pea. *H. monophylla*, a common greenhouse climber, has alternate smooth leaves, bearing a single lance-shaped or oblong leaflet two to three inches long, and prominently nerved. The racemes vary in length, but are generally longer than the leaves, and bear numerous usually blue flowers. The long carrot-shaped somewhat woody root of this plant is called by the colonists *Sarsaparilla*, and, according to Mr. Adamson, is used by the goldminers in infusion as a substitute for that root. Other species have three leaflets instead of one. The genus bears the name of Frances Countess Hardenberg, sister of Baron Hugel the eminent German traveller. [A. A. B.]

**HARDHACK.** *Spiræa tomentosa*.

**HARDHAY.** *Hypocnemum quadrangulare*.

**HARDHEADS.** *Centaurea nigra*.

**HARDOCK, or HARLOCK.** Probably the Burdock, *Arctium Lappa*.

**HARDWICKIA.** A small genus of East Indian trees, belonging to the *Cæsalpinia* group of *Leguminosææ*, and nearly related to the copalva-balsam trees of South America. The abruptly pinnate leaves in *H. binata* are composed of one, and in *H. pinnata* of three pairs of opposite unequal-sided somewhat oval leaflets; and the minute dull yellow flowers are arranged in a spiked manner in axillary or terminal panicles. Each flower consists of four or five sepals; eight to ten stamens, the alternate ones

shorter; and an ovary crowned with a short style, and a shield-like stigma. The lance-shaped pods are two to three inches long, compressed and one-seeded. Both species are trees of considerable size, and *H. binata* is said to yield a good timber suitable for many purposes. [A. A. B.]

**HAREBELL.** *Hyacinthus nonscriptus*. The name is also sometimes applied to the Hairbell, *Campanula rotundifolia*.

**HAREBURN.** *Arctium Lappa*.

**HARESBANE.** *Aconitum Lagostemon*.

**HARESBEAR.** *Verbascum Thapsus*.

**HARESEAR.** *Bupleurum*; also *Erythrum austracum* and *orientale*. — **BASTARD.** *Phyllis Nobla*.

**HARE'SFOOT.** *Ochroma Lagopus*; also *Trifolium arvense*, and *Davallia canariensis*.

**HARE'S-LETTUCE, or HARE'S-PALACE.** *Sonchus oleraceus*.

**HARE'STAIL.** *Lagurus ovatus*.

**HARETHISTLE.** *Sonchus oleraceus*.

**HARICOT.** (Fr.) *Phaseolus*. The ripe seeds of *P. vulgaris* and other species of kidney-bean are cooked under the general name of Haricots. — **A PIEDS.** *Phaseolus nanus*. — **A RAMER, BLANC, or COMMUN.** *Phaseolus vulgaris*. — **DE HOLLANDE.** *Phaseolus compressus*. — **DE LA JAMAÏQUE.** *Phaseolus lathyroides*. — **DESPAÏNE.** *Phaseolus multiflorus*. — **DE PRAGUE.** *Phaseolus sphaericus*. — **DE SOISSONS.** *Phaseolus compressus*. — **DE TONQUIN.** *Phaseolus tunkinensis*. — **EN ARBRE.** *Wistaria frutescens*. — **EN TOUFFE.** *Phaseolus nanus*. — **EN ZIGZAG.** *Phaseolus Mungo*. — **FLAGEOLET NAIN.** *Phaseolus tumidus*. — **LIMAÇON.** *Phaseolus Caracalla*. — **NAIN.** *Phaseolus nanus*. — **PRINCESSE.** *Phaseolus tumidus*. — **ROUGE D'ORLÈANS.** *Phaseolus vulgaris*.

**HARIF, or HEIRIFF.** *Galium Aparine*.

**HARINA.** A genus of East Indian palms, previously described under the name of *Wallichia*, by which they are most generally known. *Harina*, however, forms a section of the genus, characterised by having the male and female flowers upon the same plant, the males being in dense masses, and having an undivided calyx, and six stamens. [A. S.]

**HARLANDIA.** The glabrous climbing plant described under this name, and native at Hong Kong, is stated by Mr. Benthams to belong to the cucurbitaceous genus *Karibia*. [M. T. M.]

**HARLOCK.** Probably Burdock, *Arctium Lappa*.

**HARPALYCE.** A small genus of handsome erect pinnate-leaved bushes of Mexico and Brazil, belonging to the *Galega* group of the *Leguminosae*, and differing from its allies in the calyx being cleft nearly to the base and consisting of but

two narrow and entire segments nearly as long as the corolla. *H. brasiliensis*, a bush of four to eight feet high, clothed with a reddish velvety down, bears handsome scarlet pea-flowers disposed in a panicle or racemed manner towards the ends of the twigs. The Mexican species are smooth, and have purple flowers. In all, five of the ten stamens, which are united into a sheath, are shorter than the others, and have small rounded anthers. The pods are coriaceous, somewhat flattened, and many-seeded, and, as in *Cassia*, the seeds are separated by partitions. [A. A. B.]

**HARPAGOPHYTUM.** *Uncaria*.

**HARPANEMA.** \* A genus of Madagascar *Asclepiadaceae*. It is a climbing shrub with opposite glabrous coriaceous leaves, and small flowers in compound axillary cymes. The calyx is five-parted; the corolla is rotate and five-cleft; the staminal corona consists of five linear bifid hooked processes alternating with the lobes of the corolla; the anthers have a fleshy apex bent down upon the stigma; and the pollen-masses are attached by fours to the stigmatic corpuscles. [W. C.]

**HARRISONIA.** The name of a shrub with prickly branches, found in the island of Timor, and referred to the *Simarubaceae*, among which it is known by the stamens being attached to hairy two-lobed scales; by the four-lobed ovary; and by the four styles, separate at the base, but united above. The same name has been applied to an *asclepiad* with scarlet flowers, now included under *Baxtera*. [M. T. M.]

**HARSTRONG or HORESTRONG.** *Pseudanemum officinale*.

**HARTIGHSEA.** A small genus of *Melastaceae* confined to the islands of the Indian Archipelago, New Zealand, the east coast of New Holland, and Norfolk Island. They are trees of moderate height, with large pinnate leaves, and long panicles of smallish flowers, which have a small four or five-lobed calyx, five narrow petals joined together by their bases, the tube of the stamens cylindrical and fleshy, with eight or ten rounded notches at the apex, and the three-celled ovary included within a tubular disk occupying the centre of the flower. *H. spectabilis*, a native of New Zealand, forms a tree forty or fifty feet high. Its drooping panicles of pale-coloured flowers measure from eight to twelve inches in length, and grow from the main trunk or older branches. The New-Zealanders call the tree *Kohu* or *Wahabé*. Its leaves have a bitter taste, and are employed as a substitute for hops, and a spirituous infusion of them as a stomachic medicine. [A. S.]

**HARTOGIA.** A genus of *Celastraceae* peculiar to South Africa, and represented by a single species, *H. capensis*, a small much-branched tree, with opposite lance-shaped serrated leaves, and small white numerous flowers in axillary cymes or panicles. The fruits are dry elliptical two-

colled two-seeded drupes, as large as a good-sized pea. The seeds being destitute of albumen, and not surrounded by an aril, are the distinguishing characters. John Hartog, whose name is commemorated in this genus, was an early Dutch traveller in South Africa and Ceylon. [A. A. B.]

**HARTSBALLS.** *Elaphomyces*.

**HARTSHORN.** *Plantago Coronopus*.

**HARTSTONGUE.** *Scolopendrium*; also *Oleria cervina*.

**HARTWEGIA** *purpurea*. An epiphytal orchid of Mexico and Guatemala, with a short stem bearing a single lance-shaped leaf covered with brownish spots, and an erect wiry flower-scape a foot in length, with a few small bright pink flowers at the apex. It is closely related to *Epidendrum*; and is named after Mr. Theodor Hartweg, once collector in South America for the Royal Horticultural Society. [A. A. B.]

**HARTWORT.** *Tordylium*.

**HARVEST-BELLS.** *Gentiana Pneumonanthe*.

**HARVEYA** *capensis* is an erect simple herb, a parasite on the roots of heaths at the Cape of Good Hope; and constitutes a genus of *Scrophulariaceae* of the tribe *Gerrardieae*. It is nearly allied to *Aulaya*, and, like that genus, has four didynamous stamens, all bearing anthers, with one fertile ovate awned cell, and the other cell long and subulate but empty; it differs chiefly in its large inflated herbaceous calyx.

**HASHISH.** The Arabian name of the narcotic *Cannabis sativa*.

**HASKWORT.** *Campanula latifolia*.

**HASSAGAY-TREE.** *Curtisia saginea*.

**HASSELQUISTIA.** A genus of umbellifers distinguished by the petals of the central flowers being inversely ovate and slightly notched at the end, those in the circumference of the umbel spreading and two-cleft; by half of each fruit produced by the central flowers being abortive, the other partly folded round it; and by the fruits at the outer part of the umbel being flat with a thick winged border, slightly wrinkled. The genus was named by Linnaeus in honour of Hasselquist, a well-known Eastern traveller. The species are annual herbs, natives of Syria, and have the stems hairy. [G. D.]

**HASSKARLIA.** The name of a genus of Indian and Javanese *Pandanaceae*. The fruits consist of three to five or rarely more ovaries united together, each one-seeded, the seeds being like those of the allied genus *Freyetia*. [M. T. M.]

**HASTATE.** Shaped like the head of a halbert.

**HATHER.** The common Heath or Heather.

**HAUSTORIUM.** A small root which attaches itself to the surface of some other

plant, and lives by sucking it. A sucker, as in dodder, ivy, &c.

**HAUTBOIS** or **HAUTOÛY.** A kind of Strawberry, *Fragaria elatior*.

**HAUTBOIS.** (Fr.) *Sambucus nigra*.

**HAVER.** The Wild Oat, *Avena fatua*.

**HAW.** The fruit of the hawthorn, *Crataegus Oxyacantha*. —, **BLACK.** *Fiburnum prunifolium*.

**HAWKBIT.** *Apargia*; also *Hieracium*.

**HAWKNUT.** *Buntium flexuosum*.

**HAWKSBEARD.** *Crepis*.

**HAWKWEED.** *Hieracium*.

**HAWORTHIA.** One of the subdivisions of the genus *Aloe*, consisting of small curious-looking and extremely interesting succulent herbs of South Africa, distinguished by having erect flowers, the perianth with a straight tube and two-lipped limb, the stamens adherent to the base of the perianth, and the capsule ribbed. Some of the species are remarkable for the translucent substance of their leaves, or for their elegant reticulated markings. [T. M.]

**HAWTHORN.** *Crataegus Oxyacantha*. —, **INDIAN.** *Rhaphiolepis*.

**HAYLOCKIA.** One of the bipinnatifid *Amaryllidaceae* referred to a separate genus. It is a small bulb, with hiemal very narrow linear leaves, and autumnal one-flowered concealed scapes bearing a solitary white flower stained with purple. This has a cylindrical tube enlarged at the mouth, and a regular limb, funnel-shaped below and partially spreading above; the filaments of alternate length, conniving, the sepaline inserted at the base of the limb, the petaline higher; and the style erect, with a three-cleft stigma. It is allied *ranthus*, and is found in Uruguay.

**HAYMAIDS.** *Glechoma*.

**HAZEL.** *Corylus Avellana*. —, **WITCH.** *Hamamelis*.

**HAZELWORT.** *Asarum europæum*.

**HEAD-ACHE TREE.** *Premna integrifolia*.

**HEART.** **FLOATING.** An American name for *Lemnathemum*.

**HEARTS-EASE.** *Viola tricolor*.

**HEART-SEED.** *Cardiospermum*.

**HEART-SHAPED.** The same as Cordate.

**HEART-WOOD.** The central part of the timber of Exogens, hardened or altered by age.

**HEATH.** *Erica*. —, **BERRIED.** *Empetrum*. —, **IRISH.** *Menziesia* (or *Daboecia*) *polifolia*. —, **MOOR.** *Gypsocalitia*. —, **ST. DABEOG'S.** *Menziesia polifolia*. —, **SEA.** *Frankenia*.

**HEATHER.** *Calluna vulgaris*. —, **HIMALAYAN.** *Andromeda fastigiata*.

**HEATHWORTS.** Lindley's name for the *Ericaceæ*.

**HEAUMIER.** (Fr.) *Cerasus vulgaris*.

**HEBECLADUS.** A genus of *Solanaceæ*, closely allied to *Atropa*. The name is given in allusion to the downy branches of the species. The corolla is funnel-shaped, with a large tube, longer than the calyx, the limb spreading, wavy, five-cleft, frequently with small teeth intermediate between the lobes. The species are natives of tropical America, and one of them, *H. biflorus*, with yellow flowers, is cultivated in our greenhouses. (M. T. M.)

**HEBECLINIUM.** A South American genus of *Compositæ*, closely allied to *Eupatorium*, differing chiefly in the elevated and villous instead of flat and naked receptacles on which the florets are seated. The species are herbaceous or somewhat shrubby plants with opposite leaves, and the twigs are terminated by corymbs of numerous white, purple, or rose-coloured flower-heads containing tubular florets with protruding styles. One of the most handsome is the Mexican *H. lanthimum*, a good-sized bush, having the stems and branches clothed with rusty down, and the numerous flower-heads disposed in corymbs, and of a fine mauve colour. (A. A. B.)

**HEBENSTREITIA.** A genus of *Selaginaceæ*, containing sixteen species, natives of the Cape of Good Hope. They are undershrubs with alternate or scattered leaves, and membranaceous bracts surrounding the flowers. The calyx is monopetalous, and the corolla tubular at the base, with a somewhat one-lipped limb; there are four exserted stamens; and the deflexed style passes through a fissure of the corolla. (W. C.)

**HECASTOPHYLLUM.** The same as *Ecastaphyllum*.

**HECUBÆA.** A genus of *Compositæ* peculiar to Mexico, and there represented by a single species, *H. scorzoneraefolia*, a smooth unbranched herb about a foot high, furnished with a few alternate entire lance-shaped leaves, and terminal solitary long-stalked yellow-rayed flower-heads an inch or more across. The ray florets are strap-shaped and female, the strap deeply divided into three or five parts; and the disk florets are tubular, five-toothed, and perfect. The relationship of the genus is with the North American *Helianthus*, from which it differs in the achenes being destitute of pappus. The analogy of the two genera is curiously expressed in the names they bear: *Hecuba* was the daughter of Diomedes, king of Thrace, and *Helianthus* (*Helios*) was one of her sons. (A. A. B.)

**HEDAROMA.** A name sometimes given to some involucrate species of *Genetyllia*.

**HEDROMA.** A genus of labiates almost confined to the American continent, but found in various countries from Brazil to Canada. They are annual or perennial

herbs or dwarf shrubs, with small leaves and whorls of flowers borne towards the tops of the branches. The genus is principally distinguished from its allies by having only the two lower stamens fertile, the two upper ones being either short and sterile, or altogether wanting; and by the corolla being short and never of a scarlet colour. *H. pulgioides*, the Penny-royal of America, is an annual, with numerous branches, small opposite egg-shaped leaves, and small pale-blue flowers. It is found in the United States from Carolina to Canada, and is extensively used for medical purposes, particularly in domestic practice, large quantities of it being brought to the markets for sale. An infusion or tea of it is a popular remedy for colds and pains in the legs. The whole plant has a strong pungent but pleasant scent, and a mint-like taste. (A. B.)

**HEDERACEÆ.** Another name for the order *Araliaceæ*.

**HEDERA.** A genus of *Araliaceæ*, consisting of evergreen climbing shrubs, with simple exstipulate leaves, and an umbellate inflorescence. The margin of the calyx is elevated and five-toothed, the petals five, not cohering at the apex, the stamens five, the style single with five obscure stigmas, and the berries five-celled. The common Ivy, *H. Helix*, one of our wild plants, is the badge of the Gordons. This well-known evergreen climber, which mantles and peoples the picturesque ruin, adorns the winter the bare trunks of deciduous trees, clothes the hedge-row banks of rural lanes, is admitted to various uses the decoration of our gardens, and 'steals by poets the emblem of friendship.' Its stems cling by means of little rootlets to the walls or tree-trunks with which they come in contact, throwing out right and left their shining five-angled leaves, but after they have reached the summit of the object to which they cling, they branch out into woody bushy heads with simple leaves, bearing at the end of every twig a little umbel of yellowish flowers succeeded by dark-coloured berries. The plant is liable to much variation, and many interesting varieties are in cultivation. Many tropical species once referred here now form the genera *Oreopanax*, *Dendropanax*, *Agalma*, *Sciadophyllum*, &c. An ivy-clad ruin is shown in Plate 30. (T. M.)

**HEDGEBELLS.** *Calystegia sepium*.

**HEDGEBERRY.** *Cerasus avium*.

**HEDGEHOG.** *Medicago furens*.

**HEDGEMAIDS.** *Glechoma hederacea*.

**HEDWIGIA.** A West Indian tree, abounding in resin. It forms a genus of *Amruidaceæ*, among which it may be distinguished by its four-parted flowers, and by its fruit, which is fleshy externally, furrowed, with four one-seeded stones in the interior. (M. T. M.)

**HEDYCHIUM.** The handsome and fra-

HOLY CROSS ABBEY, COVERED WITH IVY

grant flowers of some of the species of this genus of *Zingiberaceæ* render them great favourites in the hothouse. They are plants with tuberous roots, herbaceous stems, clasping leaves, and a terminal spike inflorescence. The corolla consists of six segments in two rows, five nearly equal in size, the sixth or lip large notched or more deeply divided; the filaments thread-like; and the fruit capsular. The species are natives of tropical Asia. [M. T. M.]

**HEDYOSMUM.** A genus of fragrant resin-bearing shrubs belonging to the *Chloranthaceæ*. They have unisexual flowers, the males in close spikes without bracts, the females solitary or in groups of four, sessile, provided with bracts; ovary triangular. The species are natives of Brazil and other districts of tropical America. Some of them are used medicinally as antispasmodics &c. [M. T. M.]

**HEDYOTIS.** A genus of *Cinchonaceæ*, comprising a number of herbaceous or somewhat shrubby plants, dispersed throughout the tropics. The floral whorls are arranged in fours; the corolla is funnel-shaped or wheel-shaped; the ovary has two compartments, and is surmounted by an epigynous disk and cleft stigma; the fruit is a capsule. *H. umbellata* supplies a valuable red dye in Coronandel and other parts of India where it is cultivated. The Chay-root, as it is called, is the dye employed for producing the durable red colour for which the chinthees of India are noted (*Simmonds*). Wild chay-roots are preferred to cultivated ones, and licenses to dig the former are granted in Ceylon. The colouring matter resides in the rind and outer portions of the root. The leaves of this plant are also used by the natives as expectorants.

Some of the species, especially those formerly included under the genus *Houstonia*, are cultivated in gardens, their low stature, elegant appearance, and pretty flowers rendering them desirable plants for rock-work &c. The colour of the flowers varies from white to scarlet blue and purple. [M. T. M.]

**HEDYPNOIS.** A name given by Pliny to a kind of wild endive, said to have medicinal virtues, being astringent and useful in dysentery. By modern botanists the name is applied to a genus of uninteresting annual herbaceous plants with diffuse stems, toothed leaves, and yellow flowers, belonging to the *Cichoraceæ*. The generic characters are:—Receptacle naked; involucre furnished with small bracts; florets of the disk furnished with a double pappus, the outer bristly, the inner chaffy; pappus of the ray a membranous finely-toothed margin. [C. A. J.]

**HEDYSARUM.** A genus of herbaceous or somewhat shrubby leguminous plants, distinguished by the peculiar structure of the seed-pod, which is composed of numerous even one-seeded joints convex on both sides. The leaves are pinnate, with an odd leaflet; and the flowers axillary, in

stalked clusters or spikes, purple, white, or cream-coloured. The genus includes about fifty species, which are distributed throughout Europe, North Africa, and the temperate and mountainous parts of Asia, one, *H. boreale*, being found in N. America; many of them being handsome plants, and some valuable for their nutritive properties as fodder. *H. gyrans* is remarkable for the property possessed by its leaves of setting up a spontaneous motion, independent, as far as observation reaches, of all external impressions. Without being touched and without being excited by heat, light, wind, or rain, sometimes a single leaflet, sometimes a whole leaf, oscillates or gyrates, continuing to move for an indefinite time, and ceasing without known cause. Several ornamental species, as *H. capitatum* and *H. obscurum*, are cultivated in gardens; as also is *H. coronarium*, the plant commonly known in English gardens under the inappropriate name of French Honeysuckle, it being a native of Italy, and having no affinity with *Lonicera*. Its latter name it owes no doubt to its similarity to red clover, often called honeysuckle by country children from the use which they make of its sweet flower-tubes. In Spain and Italy it is gathered in great quantities as food for cattle. French and German, *Sulla*. [C. A. J.]

**HEGBERRY.** *Cerasus avium*.

**HEGEMONE.** A genus of *Ranunculaceæ*, allied to *Trollius*, found in the Altai near the limit of perpetual snow. The species on which the genus is founded, *H. lilacina*, has an erect stem, leafy at the base, the leaves palmately five-parted, those of the stem similar. The flower is solitary and terminal, pale lilac, with fifteen or twenty persistent petaloid sepals and about ten small irregular petals, having an oblong limb and short tubular base; carpels numerous sessile. [J. T. S.]

**HEIMIA.** A genus of *Lythraceæ* in which it is remarkable for its yellow flowers, blue or purple being the prevailing colour in the family. The two known species, *H. salicifolia* and *H. grandiflora*, are both smooth erect bushy shrubs, the former common to Texas, Mexico, and Buenos Ayres, the latter confined to Buenos Ayres. The willow-like leaves are opposite below and alternate above, and the yellow flowers, placed singly in the axils of the leaves, have great superficial resemblance to those of *Lysimachia vulgaris*, but in structure are widely different. According to Mr. Tweedie, both species are common in pasture lands about Buenos Ayres, and, as the cattle do not browse upon them, there is always an abundance of their gay yellow blossoms, which are called *abro sol*, 'it is open sun.' The twigs are strewn on floors to drive away fleas, of which there are abundance. The willow-leaved species is said to excite violent perspiration. The Mexicans consider it a potent remedy for venereal diseases, and call it Hanchinol (*Lindley*). The genus is

named in honour of Dr. Heim, a distinguished physician of Berlin. [A. A. B.]

**HEINSIA.** A shrub of the *Cinchona* family, native of Sierra Leone. It has spiny branches, and white flowers in clusters of three or four at the ends of the branches. The calyx has a five-parted limb with leafy segments; the corolla is salver-shaped, its tube longer than the calyx, very hairy within; anthers sessile, concealed by the hairs of the corolla; ovary two-celled; fruit dry, hard, with two indehiscent compartments; seeds numerous. *H. jasminiflora* is an evergreen stove shrub. [M. T. M.]

**HEINTZIA.** A genus of *Gesneraceae*, containing a single species from central America, an undershrub, with erect stem, opposite fleshy leaves, and axillary umbellate inflorescence. The flowers have a free five-parted calyx; a funnel-shaped corolla, tomentose on the outside, the limb cut into five roundish segments; four didynamous stamens; and a one-celled ovary surrounded by a disk, and having two bilobed parietal placentae, with numerous anatropal ovules; the simple style has a funnel-shaped stigma. The fruit is fleshy and one-celled. [W. C.]

**HEISTERIA.** A genus of small trees found in some of the West Indian islands, and also in Guiana and Brazil. They belong to the *Oleaceae*, which has very few other representatives in the western hemisphere. The flowers are produced either singly or in little clusters at the bases of the leaves. The calyx is small and five-cleft, but increases greatly in size, spreading out after flowering, and ultimately surrounding the ripe fruit; there are five petals, and ten fertile stamens. The fruit is olive-shaped, enclosed in the enlarged fleshy calyx, and contains a single seed. *H. coccones* forms a tree fifteen or twenty feet high, with shining oblong leaves, and small white flowers borne singly on short stalks. It is a native of the West Indian islands, particularly of Martinique, where the French call it *Bois perdrix*, which is a corruption of *Pois perdrix*, signifying partridge pea, the fleshy red fruits forming a favourite food of pigeons and other birds. The corrupt French name *Bois perdrix*, however, has led to the supposition that the prettily marked wood called 'Partridge wood' by cabinet-makers was derived from it; but such is not the case, the source of that wood remaining unknown. [A. S.]

**HELIOIA sanguinolenta** is a pretty cultivated terrestrial orchid from the Peruvian Andes, having the habit of *Trichopilia*, and differing from that genus, according to Dr. Lindley, in that the column, instead of being rolled up in the lip, stands erect and clear of it, the anther two instead of one-celled, and the anther bed with a deep fringed border instead of two lacerated processes. The plant has elongated ovate pseudobulbs, a single undulate leaf, and a one-flowered peduncle shorter than the

pseudobulb. The sepals and petals are olive-coloured, marked with crimson spots, and the lip white with crimson and yellow streaks. About the middle the lip contracts, and has two fleshy lobes standing erect on each side of the column, without however touching it; the space between these lobes, forming the base of the lip, is a deep hairy pit. [A. A. B.]

**HELDE.** *Tanacetum vulgare*.

**HELENIUM.** A genus of herbaceous perennials belonging to the corymbiferous tribe of compound flowers. The characters are:—Receptacle of the disk naked, of the ray chaffy; pappus five-awned; involucre one-leaved, many-parted; florets of the ray three-cleft. The species are all natives of America, and bear yellow flowers. French, *Heléne*. [C. A. J.]

**HELIAMPHORA.** A genus of plants described by Benthams, belonging to the *Sarraceniacae*. Perennial herbaceous plants found in muddy places in Guiana with radical leaves, the petiole of which is tubular and in the form of a pitcher with an

*Heliamphora nutans*.

oblique mouth; and an erect scape with nodding white or pale rose-coloured flowers. The perianth consists of four to five hypogynous imbricated parts; the stamens are indefinite and hypogynous; and the ovary is three-celled, with numerous ovules on an axile placenta. The pitchers are lined with hairs of a peculiar nature. The only species is *H. nutans*. [J. E. B.]

**HELIANTHEMUM.** A genus of low mostly prostrate shrubby or subshrubby plants, closely related to *Cistus*, from which they differ in having imperfectly three-celled, instead of five or ten-celled capsules. They are most plentiful in the warmer and temperate parts of Europe, and in North Africa, but occur also in Egypt, in Arabia, in the Canaries and adjacent isles, in North America, and even in Brazil. They are showy plants, with simple subevergreen leaves, and five-petaled fugacious flowers, mostly in ter-

minal racemes, and having a calyx of from three to four sepals, a capitate stigma, a triquetrous ovary, and a three-valved capsule. Unlike their allies, the *Cistuses*, they do not appear to have any active properties, but it is stated of the common species, *H. vulgare*, that the stamens, if touched during sunshine, spread slowly, and lie down upon the petals. Many double-flowered varieties of the cultivated species have been originated in gardens. [T. M.]

**HELIANTHUS.** A genus of *Compositæ* or *Asteraceæ*, consisting of coarse tall-growing herbs, with large rough leaves and yellow flowers. The greater portion are natives of North America.

The only species grown for culinary purposes is *H. tuberosus*, the Jerusalem Artichoke, which, although stated to be a native of Brazil, is a hardy perennial attaining the height of six or eight feet, and, with its large rough alternate heart-shaped somewhat pointed leaves, has considerable resemblance in habit and appearance to the common sunflower. The name of Jerusalem Artichoke is considered to be a corruption of the Italian *Girasole Articoceco*, or Sunflower Artichoke, under which name it is said to have been originally distributed from the Farnese garden at Rome soon after its introduction to Europe in 1617.

The roots are creeping, and towards the close of autumn produce, like the potato, a number of round irregular reddish or yellow tubers, clustered together and of considerable size. They are used either boiled and mashed with butter, or baked in pies, and when nicely cooked are not only well flavoured, but considered to be both wholesome and nutritious—more so even than the potato, as they may be eaten by invalids when debarred from the use of other vegetables. On the continent they are in considerable demand for soups, and before the potato became plentiful, they were a good deal in use in this country. Parkinson, writing in 1629, says they were then so common in London 'that even the vulgar began to despise them: they were baked in pies with marrow, dates, ginger, sack, &c., and, being so plentiful and cheap, rather bred a loathing than a liking for them.' Hence it appears that, as the culture of the potato extended, it gradually displaced the Jerusalem Artichoke, and at the present time the latter is only grown to a very limited extent in first-class gardens. Since the failure of the potato crops, the Jerusalem Artichoke has been strongly recommended as a substitute for that vegetable; but notwithstanding all that has been said and written in its favour, it is still far from common, and by no means esteemed so much as it deserves to be. [W. B. B.]

**HELIOCHRYSUM.** A genus of herbaceous or shrubby plants belonging to the corymbiferous tribe of *Compositæ*, and of which the characters are:—Receptacle naked; pappus hairy or feathery; involucre imbricated, radiate, scarious; ray coloured.

Most of the species are natives of the Cape of Good Hope. As the name 'gold of the sun' indicates, the flower-heads are beautifully radiated, and while some species are of a brilliant yellow, others are white, pink, or crimson. In all, the radiating involucre is very conspicuous, and retains much of its elegant form and brilliant colour when dried. *H. macranthum*, an Australian species, when first introduced, bore only white flower-heads slightly tinged with red outside, but varieties have now been raised which have exchanged the primitive white hue for numerous shades of red, orange, or rose-colour. Thus the plant, originally worthy of note for the large size of its heads, has acquired a new interest in horticulture. *H. orientale*, a native of Crete and Africa, is the Immortelle of the French. The flower-heads of this species are yellow, but are often dyed green, orange, or black, and are much employed in the making of wreaths intended to be votive offerings to the dead. In drying the flowers of these plants, they should be suspended head downwards. German, *Strohblume*. [C. A. J.]

**HELICIA.** A genus of *Proteaceæ* having a cylindrical club-shaped calyx with four slightly spatulate sepals, each of which bears a nearly sessile anther a little below its apex. The seed-vessel is a single-seeded follicle which does not open by valves. The leaves are ovate or oblong, five to ten inches in length, simple, scattered, sometimes opposite, herbaceous or leathery in texture, entire or toothed. The flowers grow in axillary or terminal racemes. The genus is spread over tropical Asia, extending northwards to Japan; five species are endemic to Australia. All are trees or tall shrubs. [R. H.]

**HELICOGYRATE.** Having a ring or gyrus carried obliquely round it; as in the spore-cases of *Trichomanes*.

**HELICOID.** Twisted like a snail-shell.

**HELICONIA.** A fine genus of herbaceous plants, belonging to the *Musaceæ*, and inhabiting tropical America. They are distinguished from their congeners by their fruit, which is capsular, separating into three one-seeded compartments. The shoots of *H. psittacorum* are eaten in the West Indies, as also are the fruits of *H. Bihai*. [M. T. M.]

*H. Maria Alexandrovna*, named after the Empress of Russia, a remarkable New Grenada species, with the habit of *Musa*, produces a useful fibre. Its trunk attains twelve to fifteen feet in height, and is formed of the sheaths of the leaf-stalks. The peduncles project beyond the leaves, and curving downwards bear a narrow flattened spike two and a half feet long, the red flowers of which are almost concealed by the spathe and white bracts.

**HELICTERES.** A genus of *Storckiaaceæ*, typical of the tribe *Helicteres*, containing upwards of thirty species, mostly natives of the tropics of the Western hemisphere. They are shrubs, usually covered with rusty stellate down, the

leaves simple, heart-shaped with the basal lobes unequal; the flowers in little clusters in the angles of the leaves, five-petaled, with the stamens united into a long column surrounding the stalk of the ovary, but separating at the summit into from five to fifteen filaments, partly sterile. The fruit consists of five carpels, which are generally twisted together in a screw-like manner. *H. Isora* is a native of Southern India, where its singular twisted screw-like fruit, about two inches in length, is called 'twisted stick,' 'twisted horn,' or 'twisty,' and, on account of its shape and name, is supposed to be a sovereign remedy against colic or twistings of the bowels. [A. S.]

**HELIOCARPUS.** A genus of *Tiliaceæ*, found in Mexico, Central America, and New Grenada, readily recognised among its allies by the fruits, which are thin nearly circular bodies a quarter of an inch in diameter, beautifully ciliated round the margin with a row of radiating bristles. The resemblance of the fruits to little suns is expressed in the generic name. The species, all very similar in appearance, are shrubs, or some of them forest trees of considerable size, furnished with alternate long-stalked heart-shaped usually three-lobed leaves. The minute densely clustered yellow or green flowers are disposed in panicles or cymes terminating the branches. They consist of four sepals, four petals, twelve to twenty stamens, and a bifid style surmounting a two-celled ovary, which when ripe becomes a two-seeded fruit. [A. A. B.]

**HELIOPHILA.** A large genus of *Crucifera*, with twice-folded cotyledons. All the species are from the Cape of Good Hope, and are annual herbs or undershrubs, with branched stems, and racemes of yellow white rose-coloured or more frequently blue flowers. They have a more or less elongated pod with two flat or (in the elongated pods) slightly compressed valves. The calyx is equal at the base, which distinguishes it from the allied genus *Chamifera*. [J. T. S.]

**HELIOPSIS.** A perennial herbaceous plant belonging to the corymbiferous tribe of *Compositæ*. The involucre is imbricated, the florets of the ray long and narrow, the receptacle chaffy, and the fruit four-cornered without a pappus. *H. levis*, the only species, is an American plant attaining a height of five or six feet, with rather broad serrated leaves, and large yellow flowers. [C. A. J.]

**HELIOISIS.** A term applied to the spots produced upon leaves by the concentration of the rays of the sun through inequalities of the glass of conservatories, or through drops of water resting upon them. In the latter case the destruction is seldom so complete as in the former, and the chlorophyll is merely altered, especially in the circumference, and not destroyed. Such spots sometimes, on the contrary, arise from the congelation or low temperature of the drops. They afford a nidus for minute

fungi, which are not in consequence to be considered as the cause. [M. J. B.]

**HELIOSPERMA, or HELIOSPERMA.** A proposed genus of *Caryophyllaceæ*, which may, however, be rather taken to represent a section of *Silene*. The flowers are solitary or cymose, long-stalked, with a clavate campanulate calyx. The capsule is one-celled, containing lenticular compressed seeds, having a series of prominent points round the back. *S. alpestris* and *quadrifida*, natives of central and southern Europe, belong to the section thus defined, which is by no means a natural one. [J. T. S.]

**HELIOTROPE.** *Heliotropium*, especially in a popular sense, *H. peruvianum*. —, **WINTER.** *Nardosmia fragrans*.

**HELIOTROPE.** (Fr.) *Heliotropium*. — **DRIVER.** *Nardosmia fragrans*.

**HELIOTROPIACEÆ.** A group of corollifloral dicotyledons, considered by most botanical writers as a suborder of *Ehretiaceæ*. The plants have a circinate inflorescence, regular symmetrical flowers, five stamens, and four united achenes forming the fruit. They are found in Europe and South America. See *EHRETIA-CEÆ*. [J. H. B.]

**HELIOTROPIUM.** The Heliotrope or Turnsole, is a large genus of *Ehretiaceæ*, differing from the greater number of genera in having exalbuminous seeds; from *Schleidenia*, by having a salver-shaped, not funnel-shaped corolla; and from *Tiaridium*, by the fruit not being two-lobed. They are herbs or undershrubs found chiefly in tropical and subtropical regions, but a few species reach Europe, and one, *H. europæum*, is distributed over the greater part of southern and central Europe. They are furnished with strigose hairs, entire oval oblong or lanceolate leaves, and terminal or lateral one-sided usually circinate racemes of small white or lilac flowers. The fruit is separable into four nuts, or drupes, having a thin fleshy covering. Some of the species are sweet-scented, as the *H. peruvianum*, which is much cultivated on that account; on account of their agreeable scent, its flowers get the popular name of Cherry-pie. [J. T. S.]

**HELIPTERUM.** A considerable genus of *Compositæ*, separated from *Helichrysum*, to which a large proportion of what are commonly known as everlasting flowers belong, by having the hairs of the pappus feathery (plumose) instead of rough (pilose). They are annuals or perennials found in South Africa, Australia, and Tasmania, commonly furnished with lance-shaped or linear leaves, thickly clothed with short white wool, and usually having each twig terminated by a single flower-head, though in a few species the heads are numerous and corymbose. The thin dry papery scales of the involucre, pink, yellow, or white in colour, give beauty to these flower-heads. The inner series of scales are often spread out into a flat border so as to have the appearance of

ray florets; but the florets are all tubular and minute, yellow or purple, usually perfect, a few of the outer ones sometimes female.

*H. humile*, well known as *Aphelxia humilis* in greenhouses, is one of the most handsome South African species. Its much-branched whip-like stems, clothed with compressed leaves, are terminated by a large handsome deep rose-coloured flower-head, expanding only in sunshine. Another remarkable African species, *H. eximium*, has sessile elliptical leaves clothed like the stems with close cottony wool, and having the consistence of the ears of some animal; and its flower-heads, disposed in corymbs at the ends of the branches, are of a vivid purple, not unlike those of the globe amaranth. *H. incanum* is a beautiful little Australian species a foot high growing in tufts, the flower-heads having the outer scales purple, and the inner ones white; this plant is known as Native Amaranth in Tasmania.

The name 'Everlasting flower' is promiscuously applied to the plants of this genus and their allies. Bouquets of them are sometimes seen, and when well selected and tastefully arranged, they look extremely beautiful, preserving their colour for a long period, especially if kept from dust by a glass shade. [A. A. B.]

**HELLEBORE.** *Helleborus*. —, AMERICAN WHITE. *Veratrum viride*. —, BLACK. *Helleborus niger*. —, BLACK, of the ancients. *Helleborus officinalis*. —, FALSE. An American name for *Veratrum*. —, STINKING. *Helleborus fatidus*. —, SWAMP. *Veratrum viride*. —, WHITE. *Veratrum album*. —, WINTER. *Eranthis hyemalis*.

**HELLÉBORE À FLEURS ROSE.** (Fr.) *Helleborus niger*.

**HELLEBORINE.** *Epipactis*.

**HELLEBORINE.** (Fr.) *Scorpias Lingua*.

**HELLEBORUS.** A Latinised form of an old Greek name applied to some plants of this genus, and significant of their injurious or poisonous effects when eaten. The genus is included among the *Ranunculaceæ*, and consists of perennial low-growing plants with palmate or pedate leathery leaves, five persistent sepals, eight to ten tubular petals two-lobed at the top, and several carpels each with many seeds.

The species, for the most part, are found in Southern Europe and Central Asia. Among the best known is the Christmas Rose, *H. niger*, a common plant in gardens, where it blooms in winter and early spring. Its leaves are pedate, dark, shining, and smooth, and the flower-stalk rises directly from the root, bearing one or two flowers and as many bracts; the sepals are large, white or pinkish, and petal-like, the true petals being greenish and tubular. The plant probably derives its name of Black Hellebore from its dark-coloured rootstock and the numerous fibres proceeding from it. These roots are occasionally used in medi-

cine as a powerful cathartic, but its violent narcotic and acrid properties preclude its general use. The Black Hellebore used by the Greeks has been determined by Dr. Sibthorp to be *H. officinalis*, a handsome

*Helleborus niger* (flower).

plant with a branching stem, bearing numerous serrated bracts, and three to five whitish flowers. It is a native of Greece, Asia Minor, &c. According to Pliny, Black

*Helleborus niger* (leaf).

Hellebore was used as a purgative in mania by Melampus, a soothsayer and physician, 1,400 years before Christ: hence the name *Melampodium* has been applied to the Hellebores.

Two species are found wild in many parts of England, especially on a limestone soil, though it is a matter of doubt whether they may not have been introduced at some former time. *H. fatidus*, the Bear-foot, has numerous flowers in a large loosely spreading panicle, with numerous bracts frequently exhibiting every intermediate form between the ordinary divided leaf of the plant and the ovate undivided light green bract. The flowers are globular, from the sepals converging at their extremities; their sepals are green edged with pink. It is a handsome plant, and finds a place in shrubberies from its ornamental character. *H. viridis*, the Green Hellebore, is a smaller plant with fewer flowers; the sepals are

spreading and of a yellowish-green colour. There is reason to believe that the last-named species, and probably also the others, do not flower every year or even send up many leaves, but that in certain

*Helleborus foetidus* (flowering branch).

seasons, and under favourable circumstances, the growth of the plant is more luxuriant than in others. The writer of this notice has seen the Green Hellebore in abundance one season, and found little or none of it in the following one, though to all appearance the locality had not been disturbed. On the other hand, when the plants have been purposely uprooted, as was the case in a copse near Oxford to which cattle had access, though the extirpation seemed complete, yet in two years an abundance of the plant sprang up—a fact first made known by the illness, if not the death, of some of the cattle. [M. T. M.]

**HELLWEED.** *Oscula*.

**HELMET.** The same as Galea.

**HELMET-FLOWER.** *Scutellaria*; also *Aconitum* and *Corynthes*.

**HELMINTHIA.** A common wayside composite weed of the elchomaceous group, well marked by its double involucre, the inner one of which is composed of eight to ten close scales, the outer of several large loose leafy bracts. It has hispid almost prickly stems, and leaves of the same character, the lower ones lanceolate, the upper heart-shaped embracing the stem. The flowers are in small terminal heads, of a dull yellow hue and uninteresting. The fruit, which is beaked and singularly corrugated, bears some resemblance to 'a little worm,' which is the meaning of the systematic name. The English name, Ox-tongue, has reference to the shape and roughness of the leaves. [C. A. J.]

**HELMINTHOSPORIUM.** A large genus of the dark-threaded moulds (*Dematiaceae*), characterised by their more or less elongated septate spores, which are dark like the mother threads. Many of the species are common on decayed wood; and it is conjectured that some are mere conditions of higher fungi. The genus is very close

to *Cladosporium*, which differs principally in its threads being less carbonised and its fruit less complicated. [M. J. B.]

**HELMINTHOSTACHYS.** A genus of *Ophoglossaceae* consisting of a single species, *H. sylvatica*, a pseudofern, with stout horizontal rhizomes and somewhat coriaceous fronds, which are divided into a trifolately digitato-pedate sterile branch, and a simple spicate fertile branch, on which the glomerate verticillate pedicellate tufts of spore-cases are distichously arranged, each whorl being terminated by a crest-like appendage. The veins are forked from a central costa, with the branches free. Besides Ceylon it is found in India and the islands of the Archipelago. [T. M.]

**HELONIAS.** A genus of *Melanthaceae* found in North America. They have broadly lanceolate root-leaves, from a tuberous rootstock; and a bracteated scape, bearing a dense raceme of nearly sessile flowers, which are perfect, with a perianth of six oblong persistent leaves, six long slender filaments, three revolute styles, and a three-lobed pod. *H. bullata* is found in the United States, and produces, in early spring, a short raceme of purplish flowers turning green when fading. This genus has been till lately one of the most heterogeneous; but by separating *Chamaelirion*, *Schenocaulon*, and *Amianthum*, it has assumed a more natural aspect. [J. T. B.]

**HELOSCIADIUM.** A genus of low umbelliferous aquatics, inhabiting various parts of the world, and represented in Britain by two species, of which *H. nodiflorum* is the most common. This plant is frequently found growing with water-cresses, for which it is sometimes gathered; it may, however, be distinguished, not only by its unbellate flowers, but by its crenate-serrate lanceolate leaves. No serious consequences need be apprehended from eating the leaves, as its properties are antiscorbutic, and by no means violent in their effects. [O. A. J.]

**HELOSIS.** A genus of parasitical plants inhabiting the tropical and subtropical regions of the American continent, and belonging to the *Balanophoraceae*. They have a cylindrical branched rootstock from which proceed numerous flower-stalks, bearing ovoid or globose heads of unisexual flowers: the males with a three-parted perianth and united stamens; the females with two styles. Some of the species are used as styptics. Dr. Hooker remarks that the flowers are rarely, if ever, self-fertilised, but that this process is effected by the agency of insects. [M. T. M.]

**HELOTHRIX.** A small Tasmanian genus of cyperaceous plants, belonging to the tribe *Scirpeae*, and distinguished chiefly by the inflorescence being in distichous spikelets. The two lower scales are barren, the two upper produce perfect flowers; perianthes with four bristles; stamens three; styles bifid. [D. M.]

**HELVELLEI, or ELVELLACEI.** An

order of ascomycetous *Fungi*, distinguished by the receptacle being more or less depressed, though sometimes covered at first by a veil, or the inflexed border of the receptacle. Many of the species are large, and afford good articles of food, while, on the contrary, many are small and mere botanical curiosities. It includes the esculent *Helvella*, the morels, &c., besides a multitude of species varying greatly in colour, texture, and form. In a large portion of these the receptacle is depressed, to form a cup or disk, but in others it is so raised that it becomes pileiform; the borders are then more or less closely attached to the stem, till at last they are quite confluent with it, so as to form a club-shaped body with scarcely any distinct stem, as in *Geoglossum difforme*. [M. J. B.]

**HELVELLA.** A fine genus of ascomycetous *Fungi*, distinguished by the pileate receptacle, which is hollow and barren below, and whose borders hang down on the stem, to which they are either slightly attached or quite free. The fructifying surface is even and free from pits; the asci contain large elliptic spordia with one or two nuclei. The stem is sometimes simple, but it is also at times so deeply grooved that it appears as if it were made of many confluent stems. The cinereous-black *H. lacunosa*, and the pallid *H. crispa*, are our most common species, and both of them are esculent, and when well stewed form an acceptable dish. *H. esculenta*, which has been found abundantly in pine woods at Weybridge by Mr. Currey, is now referred to *Gyromitra*, in consequence of the hymenium having many gyrose raised ribs, and is known by this character and its brown tint. It is much eaten on the continent; but in some conditions appears to be dangerous. [M. J. B.]

**HELVOLUS.** Greyish-yellow, with a little brown.

**HELWINGIACEÆ, HELWINGIA.** A natural order and a genus of monochlamydeous dicotyledons, included in Lindley's garrulous alliance of diclinous Exogens. A shrub with the leaves alternate, and the flowers clustered on the midrib of the leaves. The flowers are staminate and pistillate; perianth three to four-parted, with ovate spreading segments; aestivation valvate; stamens three to four, alternate with the segments of the perianth; ovary adherent to the perianth, crowned with an epigynous disk, three to four-celled with a pendulous ovule in each cell; stigmas three to four diverging. Fruit drupaceous, crowned by the remains of the styles and disk. It comes from Japan, and has alternate petiolate acuminate stipulate leaves, and small flowers. The young leaves of *Helwingia ruscifolia* are used in Japan as an esculent vegetable. The genus is by some placed in *Araliaceæ*. [J. H. B.]

**HÉMÉROCALE BLEUE.** (Fr.) *Funkia ovata*. — DU JAPON. *Funkia subcordata*.

**HEMEROCALLIDÆ.** The *Hemerocallis* family, a subdivision of the natural order *Liliaceæ*, which belongs to the hypogynous monocotyledons or Endogens. They are showy plants, bearing umbellate or racemose flowers, white, yellow, red, or blue. *Phormium tenax* yields New Zealand flax. *Sansevieria cylindrica* yields fibres for cordage in Africa. Examples occur in *Hemerocallis*, *Funkia*, *Agapanthus*, and *Tritonia*: see **LILIACEÆ**. [J. H. B.]

**HEMEROCALLIS.** The Day Lily, a genus of *Liliaceæ*, differing from the other tubero-fasciculate rooted lilies, by having the segments of the perianth united into a tube, and by their larger yellow or orange flowers. The leaves are all radical, very long or broadly linear, keeled, the scape branched at the top with few flowers, and a shortly trumpet-shaped perianth. They are chiefly natives of temperate Asia and Eastern Europe, though the two commonest species, *H. flava* and *H. fulva*, occur even in France. [J. T. S.]

**HEMESTHEUM.** *Lastrea*.

**HEMI.** In Greek compounds = half, or halved.

**HEMIANATROPOUS.** An ovule which is anatropal, with half the raphe free.

**HEMIANDRA.** A genus of labiates, having the calyx bell-shaped and two-lipped, the stamens four, the filaments smooth, one half of each anther alone producing pollen. The name indicates the last character above mentioned, viz. the imperfect state of an anther. The species of this genus are erect or decumbent shrubs, natives of the south-eastern parts of Australia, with narrow stiff entire leaves, bearing in their axils the solitary flowers. [G. D.]

**HEMIANTHUS micranthemoides** is a minute North American annual, constituting a genus of *Scrophulariaceæ*, scarcely differing from *Micranthemum*, by the calyx being toothed only and not lobed, and by a more irregular corolla.

**HEMICARPHA.** A genus of cyperaceous plants belonging to the tribe *Hypolitææ*, distinguished chiefly by the inflorescence being in solitary many-flowered spikes; scales imbricated, obovate-cuneate, and deciduous; stamen one; styles cleft; achenes elliptic-oblong. Steudel describes five species, which are natives of warm climates in Africa and South America. [D. M.]

**HEMICHROA.** A genus of *Amaranthaceæ*, consisting of small undershrubs from the shores of South Australia. They have alternate semi-terete exstipulate leaves, and solitary sessile axillary bibracteated flowers, with a five-leaved calyx coloured within, and two to five stamens united at the base. [J. T. S.]

**HEMICLIDIA.** A South-west Australian proteaceous genus containing a single species, *H. Baxteri*, a shrub growing about five feet in height, clothed with rigid

wedge-shaped pinnatifid leaves having sharp-pointed lobes. The involucre is imbricated; and the flowers consist of a four-cleft calyx, the concave segments of which each bear an anther. The seed-vessel is hairy, of a crustaceous texture, containing a single wingless seed. [R. H.]

**HEMIRAMBE.** A genus of *Cruciferae* from North Africa, with the habit of *Brassica*, having lyrate leaves and yellow flowers. The pod has two joints, the lower one being pear-shaped, empty or with one or two seeds, the terminal one sword-shaped, three-nerved, three or four-seeded, the beak winged, without seeds. [J. T. S.]

**HEMIOCYLIA.** A genus of *Euphorbiaceae*, consisting of a few trees or shrubs natives of East India, Java, and North Australia. Most genera of spurge-worts have three-celled ovaries, but the ovary in these plants is one-celled with two ovules, thus showing in a measure the intimate connection of spurge-worts with antidesmads. The species are smooth trees or bushes, with alternate ovate or lance-shaped entire coriaceous leaves, and minute green or white flowers in clusters in their axils, the males and females on different plants. The fruits are oval drupes not much larger than a pea, usually ripening but one seed. [A. A. B.]

**HEMIDESMUS.** A genus of *Asclepiadaceae*, containing three species of twining plants, natives of India and the Moluccas. They have opposite leaves, and small flowers on interpetiolar cymes; the calyx five-parted; the corolla rotate, with five fleshy roundish scales inserted in the throat below the sinuses and forming the staminal crown. The stamens are united at the base, free above, inserted in the tube of the corolla. The apiculate anthers four-celled; the stigma large, peltate and glabrous. The follicles are cylindrical, smooth, and very much divaricated, with comose seeds. The roots of *H. indicus* are largely employed in India as a substitute for sarsaparilla: its diuretic effect is remarkable; it acts equally well as a diaphoretic and tonic. [W. C.]

**HEMIDICTYUM.** A genus of polypodiaceous ferns belonging to the *Aspleniceae*, among which it is distinguished by having the veins parallel and not joined near the costa, but reticulated near the margin, finishing off by a straight or arcuate connecting veinlet at the edge. The typical species, *H. marginatum*, in which the marginal veinlet is straight, is a large tropical fern, with pinnate fronds of a light green colour and delicate texture, widely distributed over South America and the West Indies. [T. M.]

**HEMIDYSTROPHIA.** A term applied to express the partial nourishment of trees from the unequal distribution of their roots or from the encroachment of other trees. Trees on a wall are necessarily in this condition. [M. J. B.]

**HEMIGENIA.** A genus of labiates,

having the calyx somewhat bell-shaped, deeply five-cleft, the divisions equal; stamens four, one cell of each anther bearing pollen, the other abortive, the upper anthers hairy or bearded. They are Australian shrubs of little interest. [G. D.]

**HEMIGRAPHIS.** A genus of *Acanthaceae*, containing two species, natives of India, perennial branching villous herbs, with alternate oblong serrate leaves, and axillary flowers, either solitary or aggregated in terminal spicate heads. The calyx is unequally five-parted; the corolla funnel-shaped and resupinate, with an unequally five-lobed limb. The stamens four didynamous; the stigma is simple and pubescent. The capsule is seedless above, but contains below from six to eight echinate seeds. [W. C.]

**HEMIGYRUS.** The same as *Follicle*.

**HEMIMERIS.** A genus of *Scrophulariaceae*, consisting of small much-branched spreading annuals, with opposite leaves, and small yellow flowers in the upper axils, or clustered at the ends of the branches. The calyx is five-cleft, the corolla spreading, four-lobed, and slightly two-lipped, with two deeply-coloured depressions at the base of the lower lip. There are only two stamens, with one-celled anthers. The capsule is globular, more or less opening septically in two valves. There are three species known, all natives of the Cape Colony in South Africa.

**HEMIONITIS.** A genus of polypodiaceous ferns containing a few simple-fronded species found in the tropics of both the old and new worlds. The fronds are cordate sagittate or palmate, often profliferous, and the fertile ones generally taller. These latter are clothed with a network of closely reticulated lines of naked spores, which is the characteristic of the genus. The veins are reticulated just like the sori. [T. M.]

**HEMIPHragma heterophyllum** is a prostrate herb, often spreading to a great extent, a native of the Himalayas, forming a genus of *Scrophulariaceae*. The principal leaves along the wiry branches are small rounded and cordate, with dense clusters of short subulate secondary leaves in their axils. The flowers are small and pink, usually sessile and solitary, with a campanulate five-lobed corolla and four stamens. The fruit is a succulent capsule, almost a berry, but opening in two bifid valves.

**HEMIPHUES.** A small densely-tufted Alpine plant from Tasmania, constituting a genus of *Umbelliferae*, remarkable for the fruit, which contains only a single cell and seed. The leaves are radical, spatulate, on short pedicels, the flowers in simple umbels on short simple scapes.

**HEMIPOGON.** A genus of *Asteriadaceae*, containing two species from Brazil. They are caespitose undershrubs with rigid subulate glabrous sessile leaves in opposite

pairs or in whorls, and solitary or ternate subsessile extra-axillary flowers. The calyx consists of five acute rigid sepals. The corolla is campanulate, the limb cut into five acute erect lobes; and there is no staminal crown. [W. C.]

#### HEMISTEGIA. *Hemitelia*.

**HEMISTEMMA.** A small genus of *Dilenciaceae*, in which the stamens are situated upon only one side of the flower. The species are natives of Madagascar and the northern part of Australia; they are all small twiggy plants with yellow flowers, and resemble the rock-roses of Europe, their leaves being small, entire, and of a leathery texture, smooth above, but covered with white woolly hairs underneath. The calyx consists of five permanent sepals, the corolla of five petals; the stamens indefinite, a portion of them being sterile and resembling scales; and the two distinct ovaries are terminated by thin thread-like styles. [A. S.]

**HEMITELIA.** A genus of tree-ferns of the polypodiaceous order and the tribe *Cyathaceae*. The fronds are large herbaceous, pinnate, bipinnate, or sometimes decomposed, the veins parallel-forked or pinnate from a central costa, the basal ones arcuately anastomosing, forming elongated costal areoles from the outer side of which free venulets are given off. This venation, taken together with the presence of a half cup-shaped involucre investing the sorus, characterizes the group, except in the case of *H. speciosa*, in which the costal arc is only here and there developed. They are South American or West Indian plants. [T. M.]

**HEMITERIA.** A monstrosity of elementary organs, or of appendages of the axis.

**HEMITRICHIOUS.** Half covered with hairs.

**HEMITROPAL.** A slight modification of the anatropal ovule, in which the axis of the nucleus is more curved.

**HEMLOCK.** *Conium maculatum*. —, **GROUND.** *Taxus canadensis*. —, **WATER.** *Rhelandrium aquaticum*; also *Cicuta virosa* and *maculata*.

**HEMLOCK SPRUCE.** *Abies canadensis*.

**HEMP.** The name of various valuable fibres employed for manufacturing purposes; and also of the plants which produce them. Common Hemp is *Cannabis sativa*. —, **AFRICAN.** *Sansevieria zeylanica* and others. —, **BASTARD.** *Datisca cannabina*. —, **BENGAL or BOMBAY.** *Crotalaria juncea*. —, **BOWSTRING.** *Sansevieria zeylanica* and others. —, **BOWSTRING,** of India. *Calotropis gigantea*. —, **BROWN.** *Crotalaria juncea*. —, **BROWN INDIAN.** *Hibiscus cannabinus*. —, **INDIAN.** *Apocynum cannabinum*. —, **JUBBALPORE.** *Crotalaria tenuifolia*. —, **MADRAS.** *Crotalaria juncea*. —, **MANILLA.** *Musa textilis*. —, **SISAL.** *Agave Sisalana*. —, **SUNN.** *Crotalaria*

*juncea*. —, **VIRGINIAN or WATER.** *Acnida cannabina*.

**HEMP-WEED, CLIMBING.** An American name for *Mikania*.

**HEMPWORTS.** Lindley's name for the *Cannabinaeae*.

**HEN and CHICKEN.** The name given to a proliferous variety of the Daisy, *Bellis perennis*; also *Sempervivum soboliferum*.

**HENBANE.** *Hyoscyamus niger*.

**HENBIT.** *Veronica hederifolia*; also *Lamium amplexicaule*.

**HENDERSONIA.** One of the most striking genera of those *Coniomycetes* whose spores spring from the walls of a perithecium. The spores are always more or less articulated, and afford many exquisite objects for the microscope. Most of the species are, however, in all probability, mere states of different *Sphaeriaceae*. The most striking perhaps is one which occurs on dead reeds, the elongated spores of which have many transverse divisions, each articulation containing a large nucleus. *H. polycystis*, however, carries the division of the spores still further, having many vertical as well as transverse septa, and being moreover elegantly coated with a thick gelatinous stratum. [M. J. B.]

**HENFREYA.** A genus of *Acanthaceae*, named in honour of the late Professor Henfrey. It is a climber, differing in this respect from most plants of the order; and is also distinguished by its anthers, which have awn-like processes at the base, and by the small two-lobed stigma. There seems, however, little to distinguish the genus from *Asystasia*. *H. scandens*, a native of Sierra Leone, is an elegant stove climber. [M. T. M.]

**HENNÉ.** *Lawsonia inermis*.

**HENRIQUEZIA.** A genus of handsome bignonaceous trees of Brazil and Venezuela, exceptional in having a calyx whose tube is adherent to instead of free from the ovary, its border four instead of five-toothed; in having five perfect stamens instead of four; and in the presence of stipules to the leaves. They have oblong or obovate entire leaves placed in whorls of three to five round the stem. The handsome tubular five-lobed pink or white flowers, like those of some *Bignonia*, are disposed in dense panicles at the ends of the branches. The fruits, not the least curious part of the plant, are flat hard-shelled bodies of the shape of a bean, two-celled, opening transversely by two valves, each cell containing four seeds. The latter germinate while still in the fruit. [A. A. B.]

**HENRYA.** A genus of *Acanthaceae*, containing two species, natives of Central America. They are shrubs, with hairy glandulose petiolate and ovate leaves, and spike flowers in an involucre composed of two bracts, but apparently monophyllous from the two neighbouring margins of the bracts being united on the one side while

they are free on the other. The calyx is small and five-parted; the corolla two-lipped, the upper lip deeply bifid, and the lower cut into two spatulate lobes. [W. C.]

**HENSCHERIA.** The name applied to a shrub, native of the Philippine Islands, and of uncertain position. It is of climbing habit with trifoliate leaves, greenish flowers in axillary panicles; calyx of ten sepals in two rows; petals ten; stamens five, placed in front of the five outer sepals; ovary one-celled, with two ovules; stigmas five radiating. By Miens it is placed in the order *Phytocnaceae*. [M. T. M.]

**HENSFOOT.** *Caucalis daucoides*.

**HENSLOVIAEAE, HENSLOVIA.** A natural order and a genus of calycifloral dicotyledons, belonging to Lindley's saxifragal alliance of perigynous Exogens. Trees with opposite entire leathery exstipulate leaves, and minute dioecious racemose flowers. Perianth five-parted, lined with a woolly disk, the aestivation valvate; stamens five, alternate with the segments of the perianth, inserted on a glandular perigynous disk; ovary superior, two-celled; ovules numerous, anatropal. Fruit a capsule opening by two valves; seeds numerous, minute, exalbuminous. The genus was named after the late Professor Henslow of Cambridge. [The few species are natives of tropical India. Bentham and Hooker include *Henslowia* in *Crypteronia*, which they refer to *Lythraceae*.] [J. H. B.]

**HENSLOVIAN MEMBRANE.** The cuticle; so called because Professor Henslow was one of its discoverers.

**HENSLOWIA.** A genus of *Santalaceae*, having monœcious flowers, the perianth adherent to the ovary, with a five-cleft limb; and the stamens inserted at the base of the segments of the perianth, and shorter than them, with awl-shaped filaments, and introrse two-celled anthers. The ovary is inferior, unilocular, covered by a disk, and containing two pendulous ovules. Fruit drupaceous, one-seeded. Shrubby plants of the Indian Archipelago, with alternate nearly sessile leaves, and small greenish flowers. There are eight known species. [J. H. B.]

**HENWARE.** *Alaria esculenta*.

**HEP, or HIP.** The fruit of the Dog Rose, *Rosa canina*.

**HEPATICA.** A subgenus or section of *Anemone*, marked by having the carpels without tails, and the involucre of three simple leaves close to the flower so as to resemble a calyx. The common *H. triloba* of gardens is a native of continental Europe. In a wild state the flowers are generally blue, more rarely rose-colour or white, but in cultivation many other tints are to be found. The three-lobed leaves were fancied to resemble the liver—whence the name. [J. T. S.]

**HEPATIÆ.** The cryptogams belonging to this curious section, known popularly

under the name of Liverworts, though confounded with lichens, differ from the mosses, to which they are closely allied, in their capsule, whether opening definitely or indefinitely, never having a distinct lid, and consequently in the total absence of a peristome. In many genera there is no stem, but the leafy shoots are replaced by an expanded membranous frond which may be quite simple or repeatedly forked, while it is sometimes irregularly lobed or laciniate. Sometimes it is crisped and plicate, and sometimes furnished with gill-like plates above. Below it is generally attached to a substance on which it grows by slender delicate rootlets. In the leafy species, the leaves have rarely the same lanceolate outline so common in mosses, and they are often accompanied by stipules or lobes which give them a habit which is very distinct from that of most mosses, though the *Hypopterygi* amongst them show something of the same structure. The section comprises three distinct natural orders as follows:—

1. **RIOCIACEI**, in which the capsules are valveless, and either sunk in the frond or seated on its surface. The spores are not mixed with the spiral threads called elaters.
2. **MARCHANTIACEI**, with valvate capsules seated on the under side of a stalked target-shaped disk. Spores mixed with elaters.
3. **JUNGERMANNIACEI**, with solitary fruit splitting into four equal valves. Spores mixed with elaters.

The development of the fruit and the manner of impregnation are the same in these as in mosses. They are also extensively propagated by gemmæ. [M. J. B.]

**HEPATIUS.** Dull brown with a little yellow.

**HÉPATIQUE.** (Fr.) *Marchantia*. — **BLANCHE.** *Parnassia palustris*. — **DES JARDINS.** *Hepatica triloba*. — **DORÉE.** A common name applied to several species of *Saxifraga*. — **ÉTOILÉE.** *Marchantia polymorpha*; also *Asperula odorata*. — **PRINTANIÈRE.** *Hepatica triloba*.

**HEPTA.** In Greek composition = seven.

**HERACLEUM.** A genus of umbellifers, distinguished by having the fruit compressed from the back, each half of it with three dorsal slender ribs, and one at each marginal line, one oil-vessel in each furrow, and generally two in the commissure.

The generic name is derived from Hercules, probably in reference to the properties of some, or the size of others. The number of described species is considerable, and they are somewhat difficult to distinguish. They are widely diffused, occurring in different parts of India, in Europe and America. Several have been long known in cultivation, but are not possessed of any very special recommendations. One species has of late years been a very general object of culture on account of its large size and commanding appear-

ance, viz. *H. giganteum*, a native of Siberia. This species is easily raised, and flowers the year after being sown, or sometimes a year later still, the latter being usually the more vigorous and attaining larger size. Individuals ten to twelve feet high are common, with a circumference of stem equal to about as many inches.

Some of the species are turned to various useful purposes. Our native *H. Spondylium* is used for feeding pigs, and in Scania, according to Linnaeus, is employed as a domestic remedy. A Kamtschatkan species is had recourse to by the natives; the foot-stalks of the lower leaves, when properly treated, yield a sweet exudation which is employed in the preparation of a distilled spirit. The roots and stems of *H. lanatum* are eaten by some of the native tribes of North America. The young shoots of *H. pubescens* contain a sweet and aromatic juice, and are used as food in some parts of the Caucasus. [G. D.]

**HERB BENNET.** *Geum urbanum*; also *Conium maculatum*, and *Vale. iana officinalis*. — **CHRISTOPHER.** *Actæa spicata*; also *Osmunda regalis*, and *Pulsatilla dysenterica*. — **GERARD.** *Egopodium Podagraria*. — **IMPIOUS.** *Filago germanica*. — **IVE, or IVY.** *Ajuga Iva*; also *Coronopus Ruellii*, and *Plantago Coronopus*. — **MARGARET.** *Bellis perennis*. — **OF GRACE.** *Ruta graveolens*. — **PARIS.** *Paris quadrifolia*. — **PETER.** *Primula veris*. — **POOR-MAN'S.** *Gratiola officinalis*. — **ROBERT.** *Geranium Robertianum*. — **TRUE LOVE.** *Paris quadrifolia*. — **TRINITY.** *Viola tricolor*; also *Hepatica triloba*. — **TWOPENCE.** *Lysimachia Nymularia*.

**HERBACEOUS.** Merely green, or thin green and cellular, as the tissue of membranous leaves. Also producing an annual stem from a perennial root.

**HERBA ADMIRATIONIS.** *Leucas zeylanica*. — **ARTICULARIS.** *Silene inflata*. — **BARONIS.** *Thymus Herba barona*. — **IMPIA.** *Filago germanica*. — **INDICA.** *Ionidium enneaspermum*. — **MORRIS.** *Phyllanthus Urinaria*. — **PARIS.** *Paris quadrifolia*. — **ROTA.** *Parmica Herba rota*. — **SANCTI JACOBI.** *Senecio Jacobæa*. — **SANCTI STEPHANI.** *Circæa*. — **SENTIENS.** *Oxalis sensitiva*. — **STELLA.** *Plantago Coronopus*. — **SUPPLEX.** *Cymbidium ovatum*. — **VIVA.** *Oxalis sensitiva*. — **VULNERATA.** *Bupleurum falcatum*.

**HERBARIUM.** A collection of dried plants systematically arranged.

**HERBE À CENT GOÛTS.** (Fr.) *Artemisia vulgaris*. — **À CLOQUES.** *Physalis Alkekengi*. — **À COTON.** *Asclepias Cornuti*. — **À ÉCOURER.** *Chara*. — **À ÉTERNUER.** *Parmica vulgaris*. — **À GÉRARD.** *Egopodium Podagraria*. — **À JAUNIR.** *Genetia tinctoria*, and *Reseda luteola*. — **À L'ARAIGNEE.** *Anthericum ramosum*, and *Nigella damascena*. — **À LA COU-**

**PUR.** *Sedum Telephium*. — **À LA MANNE.** *Glyceria fruticosa*. — **À LA RATE.** *Scolopendrium vulgare*. — **À LA REINE.** *Nicotiana Tabacum*. — **À LA TAUPÉ.** *Datura Tatula*. — **À LA VIERGE.** *Narcissus poeticus*. — **À L'ÉPERVIER.** *Hypochaeris radicata*. — **À L'ESQUINANCIE.** *Asperula cynanchica*, and *Geranium Robertianum*. — **À L'HIRONDELLE.** *Passerina Stellera*. — **À PRINTEMPS.** *Chenopodium Botrys*. — **À MILLE FLORINS.** *Erythraea Centaurium*. — **À OUAÏE.** *Asclepias Cornuti*. — **À PARIS.** *Paris quadrifolia*. — **À PAUVRE HOMME.** *Gratiola officinalis*. — **À ROBERT.** *Geranium Robertianum*. — **AU CANCER.** *Herniaria glabra*. — **AU CHANTRE.** *Sisymbrium officinale*. — **AU CHARPENTIER.** *Achillea Ageratum*. — **AU LAIT DE NOTRE-DAME.** *Pulmonaria officinalis*. — **AU NOMBRI.** *Ocnoglossum linifolium*. — **AU VENT.** *Anemone Pulsatilla*. — **AUX ANES.** *Oenothera biennis*. — **AUX BOUCS.** *Chelidonium majus*. — **AUX CENT MIRACLES.** *Ophioglossum vulgatum*. — **AUX CHARPENTIER.** *Achillea Millefolium*, and *Sedum Telephium*. — **AUX CHATS.** *Nepeta Cataria*, and *Teucrium Marum*. — **AUX CINQ COUTURES.** *Plantago lanceolata*. — **AUX CUILLEURS.** *Cochlearia officinalis*. — **AUX CUREDENTS.** *Ammi Visnaga*. — **AUX ÉCUS.** *Lysimachia Nummularia*, and *Lunaria biennis*. — **AUX FEMMES BATTUES.** *Tamus communis*. — **AUX GOUTTEUX.** *Egopodium Podagraria*. — **AUX GUEUX.** *Clamptis Vitalba*. — **AUX HÉMORRHOÏDES.** *Ficaria vancouverioides*. — **AUX MAGICIENNES.** *Circæa Luteoliana*. — **AUX MAMÈLLES.** *Lapsana communis*. — **AUX MASSUES.** *Lycopodium clavatum*. — **AUX MITES.** *Verbascum Blattaria*. — **AUX PANTHÈRES.** *Doronicum Pardalanchæ*. — **AUX PERLES.** *Lithospermum officinale*. — **AUX POUMONS.** *Pulmonaria officinalis*. — **AUX POUX.** *Delphinium Staphisagria*, and *Pedicularis palustris*. — **AUX PUCES.** *Plantago Psyllium*. — **AUX SERPENTS.** *Trichosanthes anguina*. — **AUX SONNETTES.** *Fritillaria imperialis*. — **AUX SORCIÈRES.** *Circæa Luteoliana*. — **AUX TEIGNEUX.** *Trussilago Petasites*. — **AUX VERRUES.** *Chelidonium majus*, and *Helleboreum europæum*. — **AUX VIPÈRES.** *Echium vulgare*. — **BLANCHE.** *Diota candidissima*. — **CACHÉE.** *Lathraea clandestina*. — **CANICULAIRE.** *Hypochoeris niger*. — **CHASTE.** *Vitis Agnus castus*. — **ŒUR.** *Pulmonaria officinalis*. — **D'AMOUR.** *Reseda odorata*. — **DE GUINÉE.** *Panicum altissimum*. — **DE L'HIRONDELLE.** *Chelidonium majus*. — **DE LA BAIE D'HUDSON.** A kind of *Poa*. — **DE LA SAINT JEAN.** *Hypericum perforatum*. — **DE LA TRINITÉ.** *Hepatica triloba*. — **DE SAINTE APO-**

LINE. *Hyoscyamus niger*. — DE SAINTE BARBE. *Barbarea vulgaris*. — DE SAINT ÉTIENNE. *Circea Lutetiana*. — DE SAINT FIACRE. *Heliotropium europæum*. — DE SAINT INNOCENT. *Polygonum Hydropiper*. — DE SAINT JOSEPH. *Scabiosa succisa*. — DE SAINT ROCHE. *Inula dysenterica*. — DES FEMMES BATTUES. *Bryonia dioica*. — DES MAGICIENS. *Datura Stramonium*. — DU BON HENRI. *Chenopodium Bonus Heriaca*. — DU CARDINAL. *Symphytum officinale*. — DU DIABLE. *Datura Stramonium*, and *Plumbago scandens*. — DU GRAND-PRIEUR. *Nicotiana Tabacum*. — DU SIÈGE. *Scrophularia aquatica*. — DU VENT. *Anemone Pulsatilla*. — EMPOLSONNÉE. *Atropa Belladonna*. — MAURE. *Roseda odorata*. — MORE. *Solanum nigrum*. — MUSQUÉE. *Adoxa Moschatellina*. — SACRÉE. *Melittis Melissophyllum*, *Nicotiana Tabacum*, and *Verbena officinalis*. — ST. CHRISTOPHE. *Actæa spicata*. — ST. PIERRE. *Crythimum maritimum*. — SANS COUTURE. *Ophioglossum vulgatum*.

**HERBERTIA.** A genus of dwarf bulbous fridaceous perennials from Texas and Chili, one species found in Brazil. They have narrow acute radical leaves, and a short scape bearing at top several pretty blue or yellow flowers, which have a short-tubed six-parted perianth, with the outer segments triangular, acute, and reflexed, and the shorter inner ones rounded and erect, three monadelphous stamens inserted at the base of the exterior segments, and a three-celled ovary, crowned with three trifid stigmas having recurved petaloid branches. The genus, which is allied to *Cypella* and *Iris*, is named in honour of the late Dean of Manchester, who was a high authority on all matters relating to bulbous plants. [T. M.]

**HERCULES' CLUB.** *Xanthoxylon Clava Herculis*.

**HÉRISSONNE.** (Fr.) *Erinacea pungens*.

**HERITIERA.** A genus of *Sterculiaceæ*, containing two trees of considerable magnitude, found on the coasts of India, Africa, and many islands of the eastern hemisphere; in a cultivated state only in the West Indies. They are pyramidal trees with large handsome stalked entire alternate leaves of a silvery white underneath, this silvery appearance giving rise to the name of 'Looking-glass tree,' sometimes applied to them. The blades in *H. macrophylla* are eight to fourteen inches long by four to six broad. The fine foliage and symmetrical habit of this species render it a beautiful object in a plant stove where it has space to grow. The minute reddish-coloured unisexual flowers are disposed in terminal panicles; they have a five-lobed or toothed calyx: the sterile with five sessile anthers united into a tube, and the fertile with five sessile ovaries which become, when ripe, hard nearly boat-shaped carpels. They usually ripen but one seed, and do

not open when ripe, in this respect differing from *Sterculia*, as well as in their less numerous stamens. C. L. L'Héritier, whose name is here perpetuated, was a distinguished French botanist. [A. A. B.]

**HERMANNIÆ.** A tribe of the order *Sterculiaceæ*, distinguished by the following characters:—Petals flat; stamens monadelphous at the base, equal to the petals in number and opposite to them, all fertile; ovary one or many-celled, with two or many ovules in each cell. They are herbs or shrubs found in intertropical regions, but most abundant at the Cape of Good Hope. The group includes the genera *Wulheria*, *Melochia*, *Biedleia*, *Phyodolium*, *Hermannia*, and *Mahernia*. [J. H. B.]

**HERMANNIA.** An extensive genus of *Sterculiaceæ*, including about eighty species. The chief features of the genus are:—A bell-shaped five-cleft calyx; five clawed petals, the claws hollowed; five stamens, with their filaments flattened, but not dilated above the middle in the form of a + as in *Mahernia*; and a five-celled ovary, which, when ripe, is a five-angled capsule with many seeds. The species are twiggy undershrubs, having the stems and leaves, especially the latter, which are often accompanied with leaf-like stipules, more or less clothed with starry hairs. The pretty nodding sometimes sweet-scented flowers are pale yellow, orange, or reddish-coloured, disposed in dense clusters or loose racemes or panicles at the ends of the twigs. The genus bears the name of Paul Hermann, once professor of botany at Leyden. [A. A. B.]

**HERMAPHRODITE.** Containing both stamens and pistil.

**HERMAS.** A genus of umbellifers, characterised by the calyx having a five-parted persistent border; and the fruit ovate, each half with five ribs, the middle one prominent, those on each side of it larger, the other two smaller. The species are small Cape herbs, with soft downy undivided leaves. The outer flowers of the umbels have stamens only, the others have both stamens and pistil. [G. D.]

**HERMINIERA.** A genus of tropical African trees, of the leguminous family, having thorny branches, abruptly pinnate leaves, and large orange-coloured flowers, succeeded by linear oblong compressed legumes, which become at length spirally twisted. The wood of *H. elaphrozydon*, the only species, is very white, remarkably soft, having the appearance of a mass of pith, with the medullary rays and annual rings almost imperceptible. The natives apply it to various uses. [T. M.]

**HERMINIUM.** A genus of terrestrial orchids, with small flowers very nearly allied to those of *Orchis*, but the perianth has no spur, and the anther-cells are distant at the base, the glands of the stalks of the pollen-masses protruding below the

cells. There are but very few species, all natives of the northern or Alpine regions of Europe and Asia. *H. Monorchis*, the Musk Orchis, the most common and widely-spread species, is occasionally found in southern and eastern England. It has globular tubers like those of an *Orchis*, but the new one is always produced at some distance from the stem at the end of a thickish fibre, so that the plant moves each year to a distance of one or more inches from the spot it previously occupied. The stem is slender, three to six inches high, with two or three narrow leaves near its base. The flowers, in a terminal spike, are small, of a yellowish green, with narrow sepals and petals.

**HERMIONE.** One of the divisions of the genus *Narcissus*, kept separate by some botanists, and consisting mainly of the plants which in gardens bear the name of *Polyanthus Narcissus*. According to Herbert, the distinctions are: that the cup is shorter than the slender cylindrical tube of the flower; the stamens with conniving filaments, adnate unequally near the mouth of the tube, and free only at the curved point; and incumbent acute-oval anthers attached by the middle; and the straight slender style. Most of the *Narcissus* imported along with hyacinths from Holland, for spring flowering in gardens, are of this group. [T. M.]

**HERMODACTE.** (Fr.) *Iris tuberosa*.

**HERMODACTYLUS.** The name of a few Eastern plants often included in *Iris*, but sometimes regarded as distinct. They have fleshy tubers, glaucous quadrangular leaves much longer than the stem which supports the curious black and green velvety flower, very small inner perianth-segments, and an oblong ovary narrowed to each end. *Iris tuberosa*, the typical species, is often called the Snake's-head *Iris*. [T. M.]

**HERNANDIA.** A genus of apetalous Exogens, the station of which in the natural system is regarded as doubtful: by some it has been separated as the type of a distinct family, the *Hernandiaceae*. It consists of three or four or perhaps more species, tropical trees inhabiting both the East and West Indies and Guiana. The leaves are cordate, petiolate, and smooth; and the flowers, which are monœcious, are in panicle masses, having a yellowish appearance from the sepals being petaloid. The male flower has six sepals, and three stamens opposite the three outer sepals; between the bases of the stamens are three pairs of glands. The anthers open by two valves, reflected laterally. The female flower, the structure of which has hitherto been imperfectly understood, proves on examination to have the ovary inferior, and at its base external to the calyx it is enclosed by a cup-like involucre, which in the male flower is wanting. The sepals are eight, or sometimes in imperfectly hermaphrodite flowers nine, and it has four barren stamens which are like the glands of the

male flower. The ovary is one-celled, containing one pendulous ovule; the style is short, furrowed on one side, and the stigma is broad and lobulated. The seed, in which the radicle is superior, contains no albumen, and the embryo has a crumpled appearance, in addition to which each cotyledon is three-lobed at its base. By its valvular anthers it is nearly related to *Lauracea*, but in its inferior ovary it is nearer *Combretacea*, and its station consequently is near *Gyrocarpus* and *Illigera* in the latter family, the flowers of these genera having no petals, and their anthers opening by valves. The bark, seed, and young leaves of *H. sonora* are slightly purgative. It is said that the fibrous roots chewed and applied to wounds caused by the Macassar poison form an effectual cure. The juice of the leaves is a powerful depilatory, destroying hair wherever applied without pain. The wood is light; that of *H. guianensis* takes fire so readily from a flint and steel, that it is used as amadou. [B. C.]

**HERNANT SEEDS.** The commercial name for the seeds of *Hernandia ovigera*, used for dyeing.

**HERNIARIA.** A genus of *Illecebracea*, found in barren places in the temperate regions of Europe, Asia, and Africa. They are small annuals or undershrubs with oval, oblong, or linear leaves, and small scarious stipules. The minute flowers, in lateral clusters generally arranged in an interrupted leafy spike, have a five-parted calyx, five petals reduced to mere threads, five stamens, two stigmas, and a membranous utricular fruit. *H. glabra* is a native of Britain, and not unfrequent in the southwestern counties. [J. T. S.]

**HERNIOLE.** (Fr.) *Herniaria glabra*.

**HERON'S BILL.** *Erodium*.

**HERPESTIS.** A genus of *Scrophulariaceae*, allied to *Gratiola*, and having, like that genus, didynamous stamens, with two-celled anthers, and a capsule opening septicidally in two entire or bifid valves. It is, however, readily known by the calyx consisting of five distinct very unequal sepals, the lowest outer one always much larger than the others, and the two innermost often very narrow. There are above forty species known, natives of various parts of America, Africa, Australia, or southern Asia. They are all herbs, mostly procumbent or prostrate, more rarely erect, with rather small flowers usually yellow or pale blue. The most common are, *H. Monnierea*, a small creeping glabrous plant, with rather thick entire leaves, and a pale blue or nearly white flower, very abundant in almost all hot countries in moist situations; and *H. chamædryoides*, a much-branched spreading species with ovate toothed leaves and yellow flowers, common in the mountainous districts of America from South Brazil to Mexico.

**HERRERIA.** A genus of *Liliaceae* of doubtful affinity, having the habit of the

*Asperogen*, but in structure resembling the *Anthericum*. They are undershrubs found in Brazil and Chili, with tuberous root-stock, climbing stems, whorled-fascicled lanceolate or linear leaves, and small scented flowers in many-flowered axillary racemes. The perianth is herbaceous, six-parted, persistent; the stamens six; the capsule membranaceous, three-winged, and three-celled. [J. T. S.]

**HERSCHELIA** *caelestis* is the name of a terrestrial orchid of South Africa, with a stem a foot high, bearing at the base a number of narrow grassy leaves, and ending in a raceme of pretty flowers an inch across and of an intense sky-blue colour—therefore most appropriately named by Dr. Lindley in honour of Sir John Herschel, the celebrated astronomer. The upper sepal is helmet-shaped, spurred near the base, larger than the lower ones, and hiding the petals. The beak is trilobed, and between it and the anthers is a curious forked linear appendage. [A. A. B.]

**HESPERANTHA.** A genus of Cape *Iridaceæ* closely allied to *Ixia*, the species remarkable for expanding their sweet-scented flowers in the evening—whence the name. They are bulb-tuberous plants with sword-shaped leaves; and the flowers, which grow in loose spikes, have a long-tubed hypocrateriform perianth with six equal spreading limb-segments, three stamens inserted in the perianth tube, and three stigmas, which are elongate narrow-linear and conduplicate. The flowers are mostly white, sometimes stained outside with some dark colour. [T. M.]

**HESPERIDÆÆ.** A name given by Linnaeus to a natural order comprising the genera *Citrus*, *Sitrag*, and *Garcinia*. It has sometimes been applied to the orange family. Endlicher gives the name *Hesperidææ* to one of his classes embracing the orders *Humiriacæ*, *Olatineæ*, *Aurantiacæ*, *Meliaceæ*, and *Cedrelaceæ*. It is thus defined:—Trees or shrubs with alternate exstipulate usually compound leaves. Ovary free, imbricate in maturation; corolla with petals equal in number to the segments of the calyx, valvate or convolute in maturation; stamens twice or four times the number of the petals, free, monadelphous or polyadelphous; carpels numerous, united into a one or many-celled ovary; ovules solitary or many, usually anatropal; embryo very often exalbuminous; cotyledons mostly fleshy. [J. H. B.]

**HESPERIDIUM.** A many-celled superior indehiscent fruit, pulpy within, and covered by a separable rind; as the orange.

**HESPERIS.** The Rocket, a genus of *Crucifera*, belonging to the section having the radicle of the seed bent over the back of one of the flat cotyledons. It is distinguished from *Malcolmia* by the blunt not sharp-pointed lobes of the stigma at the end of the long cylindrical pod. They are biennial or annual (rarely perennial) herbs with somewhat the habit of the stock, but

usually with less stellate pubescence. The flowers are large, purple, lilac, white, or dirty yellow; in some of the species sweet-scented in the evening, whence the generic name. The common garden Rocket, or Dame's Violet, is *H. matronalis*, a native of Europe, but probably not indigenous to Britain; many varieties exist in cultivation, with white, purple, variegated, or double flowers. [J. T. S.]

**HESPEROMELES.** The name of a few shrubs or trees of considerable size belonging to the *Pomaceæ*, and found at elevations of eight to thirteen thousand feet on the Andes of Peru and New Grenada. They have alternate stalked coriaceous ovate or oblong leaves, and white or pink flowers much like those of the hawthorn in size and disposition. From this genus they chiefly differ in the ovaries, five in number, having each but one instead of two ovules. The fruits are also like those of the hawthorn. *H. lanuginosa* grows to a large tree in New Grenada; Mr. Purdie remarks that it forms the entire forest, beginning at ten thousand and reaching to fourteen thousand feet, or near the perpetual snow limit. *Hesperomeles* signifies Western Apple. [A. A. B.]

**HESPEROSCORDON.** A genus of *Liliaceæ*, differing from *Brodiaea* by having all the six stamens anther-bearing, and the ovary sessile. They are herbs found in western North America, having much the habit of some species of *Allium*, and with large white or bluish flowers. [J. T. S.]

**HESSEA.** A small genus of *Amaryllidaceæ*, characterised by having a bifid spathe, a short-tubed regular-limbed perianth, equal subulate filaments becoming reflexed and bearing short anthers, a filiform style, and a trifid fimbriated stigma. It is represented by the *Amaryllis stellaris* of Jacquin. The name *Hessea* has also been given to the genus *Carpolyza*. [T. M.]

**HETERIA.** A small Australian marsh plant, belonging to the *Philydraceæ*, and differing from *Philydrum* by its kidney-shaped anther lobes, its central placenta ultimately detached from the three valves of the capsule, and by its smooth seeds. *H. pygmaea* is a small rush-like plant with a spike of flowers of a yellow colour and invested by bracts. [M. T. M.]

**HETERANTHERA.** A genus of *Pontederaceæ*, consisting of small aquatic herbs with roundish long-stalked or linear leaves, and one or two small white or blue flowers produced from a spathe in the axil of a sheathing leaf-stalk. The perianth is salver-shaped, with a long slender tube and a spreading six-lobed limb. *H. reniformis*, the Mud Plantain, with roundish kidney-shaped leaves and white flowers, is not unfrequent by the muddy banks of streams in the Southern United States. [J. T. S.]

**HETEROCARYUM.** A genus of *Borraginaceæ*, natives of temperate Asia, resembling *Omphalodes*, but having the calyx segments caducous, the column of styles

adhering to the nuts as far as their middle, and the peduncles thickened. [J. T. S.]

**HETEROCEPHALOUS.** Bearing, in the same individual, heads of entirely male flowers, and others entirely female.

**HETEROCHÆNIA.** A genus of bell-works, having the tube of the calyx obconical, deeply five-cleft, with the lobes ciliated; seed-vessel three-celled, opening first by three valves at the summit, subsequently by rupture of other parts. The genus was founded by De Candolle, to include the Mascaren plant formerly called *Wahlenbergia ensifolia*. [G. D.]

**HETEROCODON.** An annual from the Oregon territory in North America, distinguished as a genus of *Campanulaceæ* by Nuttall, on account of the lower flowers having no corolla; but it is probably only a form or variety of *Specularia perfoliata*.

**HETERODON.** A genus of bruniads, distinguished by the calyx having ten teeth, five of which are short and blunt, and five elongated. The only species is a shrub, a native of the Cape, having semicylindrical leaves, which are hairy, ending in awn-like points. [G. D.]

**HETEROGAMOUS.** When in a capitulum the florets of the ray are either neuter or female, and those of the disk male.

**HETEROIDEOUS.** Diversified in form.

**HETEROLÆNA.** A subdivision of *Pimelea* in which the capitula are terminal, and the involucre formed of four rarely five to eight leaves, and these leaves are unlike the foliage of the branches, differing in magnitude or in form and texture, often coloured. They are shrubby plants of New Holland and Tasmania, with opposite leaves. There are thirty-eight species of *Pimelea* in this subdivision. [J. H. B.]

**HETEROLEPIS.** A small genus of *Compositæ*, nearly related to *Gasania*, and found in South Africa. The species differ from this and their other allies, in having the hairs of the pappus (which are of unequal length and ciliated) in two or three series. All are branching bushes, with rosemary-like leaves, and handsome flower-heads with the florets all yellow. [A. A. B.]

**HETEROMORPHA.** A genus of umbellifers, distinguished from its congeners by its peculiar fruit, which is apparently five-winged owing to the different aspect of its two halves, the outer being provided with two wing-like ridges, the inner with three. The species are natives of the Cape of Good Hope. [G. D.]

**HETERONEMEÆ.** A name applied to the higher cryptogams by Fries to express the fact of the more complicated germination than in the lower cryptogams. The production of the pseudocotyledons in ferns appears to be what he had more especially in view. It may, however, be objected that in *Puccinia* and some other fungi there is a decided prothallus preceding the formation of true fruit. [M. J. B.]

**HETERONEURON.** *Paecliopteria*.

**HETEROPAPPUS.** The name formerly given to a few *Compositæ* of North China and Japan, with flower-heads like *Aster*. They are now known to belong to the genus *CALLIMERIS*: which see. [A. A. B.]

**HETEROPHRAGMA.** A genus of *Bignoniaceæ*, containing a single species from India. It is a large tree with opposite or ternate impari-pinnate leaves, and whitish flowers in dense terminal downy panicles. The calyx is campanulate and three-lobed; the corolla equally five-parted, with the margins of the divisions waved; there are four fertile stamens; the ovary is surrounded by a purple disk, and surmounted by a simple style and a two-cleft stigma; the capsule is long and pointed; and the seeds have a broad wing. [W. C.]

**HETEROPOGON.** A genus of grasses belonging to the tribe *Andropogoneæ*, now included in *Andropogon*. They are mostly natives of Mexico. [D. M.]

**HETEROPSIS.** A genus of Brazilian plants, of the family *Araceæ*, deriving its name from the fact that the appearance of the plant is different from that of most of its congeners. The stem is woody and branching, with lance-shaped leaves; the spathe hooded, deciduous; spadix blunt, covered with male and female flowers, intermixed; the anthers are two-celled and gaping; ovaries two-celled, with two ovules in each cell. [M. T. M.]

**HETEROPTERIS.** A genus of American climbing shrubs, with yellow or bluish flowers, belonging to the *Malpighiaceæ*. Several are cultivated as evergreen stove climbing plants; their flowers have a calyx with eight glands; stamens all fertile; styles three; fruit with a wing thickened on the lower margin. [M. T. M.]

**HETEROS.** In Greek compounds = variable, or various.

**HETEROSTEMMA.** A small genus of *Asclepiadaceæ*, natives of India and the Moluccas. They are glabrous twining shrubs, with opposite membranaceous leaves, and flowers in few-flowered interpetiolar umbels. The calyx consists of five ovate sepals; the corolla is rotate and five-parted, with spreading lobes. The five-leaved staminal crown is very variable, differing in each species. The foliodes are smooth and divaricate, and contain about twenty comose seeds. [W. C.]

**HETEROTOMA.** The name of a Mexican herbaceous plant, constituting a genus of *Lobeliaceæ*. It has a two-lipped calyx; a tubular corolla, the tube of which is irregularly dilated at the base into a spur-like form; anthers cohering, the two lower ones hairy; ovary with two compartments; stigma two-lobed. The flowers are large, purple, arranged in racemes. *H. lobelioides* is the Bird-plant of Mexico. [M. T. M.]

**HETEROTROPA.** The name applied to a genus of *Aristolochiaceæ*, represented by a Japanese herb, with a coloured pitcher-

shaped perianth contracted at the throat, where it is provided with a plicated ring or 'corona.' The anthers are twelve in number, arranged in two rows: the outer, on triangular filaments, open inwardly, and are partially united together; the inner ones are sessile, open outwardly, and have their connective prolonged into a lance-shaped point. The plant has the appearance of *Asarum*, from which genus the above characters amply distinguish it. Its leaves are heart-shaped, marked with white spots. [M. T. M.]

**HETEROTROPAL.** Lying parallel with the hilum. A term applied only to the embryo.

**HÊTRE.** (Fr.) *Fagus sylvatica*.

**HEUCHERA.** A genus of perennial herbaceous plants of elegant appearance, natives of North America and Siberia, and included in the *Saxifragaceae*. The petals are five, inserted into the upper part of the tube of the calyx, of a linear form and slightly unequal; stamens five, inserted with the petals; ovary one-celled, with two parietal placentae; styles elongated, divergent; fruit bursting between the styles. The flowers are borne in clusters which rise from a number of lobed toothed leaves. Several of the species are grown in English gardens. The root of *H. americana* is so astringent that it is called Alum root. [M. T. M.]

**HEWARDIA.** A genus of polypodiaceous ferns, agreeing with *Adiantum* in all the essential points of fructification, but distinguished from it by having the veins reticulated. They have linear continuous sori, as in *Adiantum Wilsoni* and its allies, and are pinnate, bipinnate, or pedately tripinnate plants of South America. It is named after Mr. R. Heward, an amateur pteridologist, and one of the contributors to this work. The name has also been given to a melanthaceous stemless herb from Tasmania, having ensiform distichous leaves, and star-shaped purple flowers, and the habit of an *Iris* or *Sisyrinchium*; but for this the name of *Isophytis* has been suggested. [T. M.]

**HEXA.** In Greek compounds = six. Thus: *Hexaleptidous*, consisting of six scales; *Hexapterous*, having six wings or membranous expansions; *Hexapyrenous*, having six stones; *Hexapetaloid*, consisting of six coloured parts, like petals; *Hexandrous*, having six stamens.

**HEXACENTRIS.** A small genus of *Acanthaceae*, containing three species from India. They are climbing shrubs with dentate leaves, and purple or yellow flowers in axillary and terminal many-flowered racemes. The small calyx is unequally toothed, and is surrounded by two small bracts. The corolla has a short tube and an oblique five-cleft limb. The four didynamous stamens have erect two-celled anthers, which, in the shorter pair, have both cells spurred, and the longer pair have a spur on one only. A short subulate sterile fifth stamen is

present. The stigma is bifurcate. *H. mysorensis* is very ornamental. [W. C.]

**HEXADESMIA.** A few epiphytal orchids of Central America, differing from *Epidendrum* in having six instead of four pollen-masses; whence the generic name. They are tufted plants a few inches high, with narrow oblong pseudobulbs, a few short grassy leaves, and a number of inconspicuous green or white flowers in a terminal raceme. [A. A. B.]

**HEXAGONIA.** A fine genus of porobearing *Fungi*, distinguished by its large angular pores, which resemble the cells of a honeycomb. Most of the species are hard and woody, but one or two are thin and flexible as paper. They are, with but one or two exceptions, inhabitants of tropical countries. We have no species in Great Britain, but *H. sericea* is found in the forests above Canada. One or two species are found on gum trees in Australia. In some Indian species the pores are one-sixth of an inch across. [M. J. B.]

**HEXALOBUS.** A genus of anonaceous shrubs, inhabiting Senegal and Madagascar. They have a six-cleft corolla, with the spreading segments in two rows; numerous club-shaped stamens, attached to the sides of a convex receptacle; and numerous ovaries with sessile stigmas; fruit of several few-seeded berries. [M. T. M.]

**HEYNEA.** A genus of Indian trees belonging to the *Meliaceae*, among which they are distinguished by the tube formed by the union of the stamens, which is deeply five-cleft, the segments being also cleft; the anthers are ten, sharply pointed; ovary two-celled, imbedded in a fleshy disk, and ripening into a somewhat fleshy capsular fruit, which is one-celled by abortion and single-seeded. [M. T. M.]

**HIANS.** Gaping; opening by a long narrow fissure cut across the shorter axis.

**HIBBERTIA.** A genus of *Dilleniaceae* confined to Australia and Tasmania, comprising about fifty species. They usually form little heath-like tufted shrubs, or their slender stems trail along the ground, but occasionally they grow several feet in length and climb upon other shrubs. Their flowers are yellow, borne at the ends of the branches, and generally give out a very unpleasant odour; they have five thick leathery permanent sepals, and five thin fugaceous petals; the stamens are very numerous, entirely free or united at their bases into several bundles; and the one-celled ovaries, two to five in number, are terminated by a diverging style. The fruit consists of two or more carpels splitting open down the inner edge, and containing one or several roundish shining seeds, each partly surrounded by an aril.

*H. densata*, a climbing species, is one of the most showy, and grows six or eight feet high. *H. grossulariæfolia* is another of the climbing kinds, having leaves somewhat resembling those of the common gooseberry bush, its trailing stems tinged with red, and

its flowers produced in great abundance at the ends of little side branches. *H. volubilis*, the largest species of the genus, has a stiff climbing stem, and pale yellow flowers two inches across, but most disagreeably scented. [A. S.]

**HIBERNAOULUM.** The poetical name of a bud or bulb.

**HIBERNAL.** Of or belonging to winter.

**HIBISCUS.** The Rose-mallow group, a very large genus of *Malvaceae*, characterized by their large showy flowers being borne singly upon stalks towards the ends of the branches; by having an outer calyx or involucre composed of numerous leaves, and an inner or true calyx cut into five divisions at the top, which does not fall away after flowering; by having five petals broad at top and narrow towards the base, where they unite with the tube of the stamens; and by the latter forming a sheath round the five-branched style, and emitting filaments bearing kidney-shaped anthers throughout the greater part of its length. The fruit is five-celled, with numerous seeds. The majority of the species are tropical, but a few are found in temperate regions, and one, *H. Trionum*, occurs in the South of Europe and also in New Zealand. Most of them are shrubs, but a few form moderately high trees. All possess the mucilaginous properties common to the order, and several are eaten as pot-herbs, while their inner bark yields more or less fibre.

*H. cannabinus* has a prickly stem, six or eight feet high, and deeply-parted leaves somewhat resembling those of hemp. The flowers are pale yellow with a dark purple blotch at the bottom of each petal. This is a native of the East Indies, where it is cultivated on account of the fibre contained in its stems, the seeds being sown thickly so as to induce the plants to grow up tall, straight, and unbranched. The fibre, like that of other malvaceous plants, bears more resemblance to jute than to hemp, though it is sometimes called Indian Hemp. It comes to this country in small quantities, and is sometimes called Bastard Jute. In Western India the plant is called Ambaree, and its leaves are eaten as a pot-herb, and an oil is extracted from its seeds.

*H. Rosa sinensis*, a well-known ornament of our hothouses, is a native of India, China, and other parts of Asia. It is a tree of twenty or thirty feet high; and has very variable flowers—double, single, red, dark purple, yellow, white, or variegated, according to the particular variety. These flowers contain a quantity of astringent juice, and when bruised rapidly turn black or deep purple; they are used by the Chinese ladies for dyeing their hair and eyebrows, and in Java for blacking shoes, whence the plant is frequently called the Shoe-black Plant.

*H. syriacus*, commonly called *Aithya frutes*, is a hardy deciduous shrub, with large showy flowers, produced in great profusion in the autumn months. [A. S.]

**HIBISCUS, BASTARD.** *Achania Malva-viscus*.

**HICKORY.** *Carya*.

**HIDDEN-VEINED.** Having the veins so buried in the parenchyma, that they are not visible upon external inspection.

**HIERACIUM.** A large and exceedingly difficult genus of cichoraceous plants, mostly with yellow flowers, inhabiting the temperate countries of the eastern hemisphere, and distinguished among allied genera by having a brown brittle pappus and no beak to the fruit. From twenty to thirty species are indigenous to Britain, growing in hedges, woods, and mountains. One of the best known and most attractive of these is *H. Filosella*, common on heaths and in dry pastures, a dwarf plant with creeping leafy scions, elliptical leaves clothed above with scattered long hairs, and bearing on leafless stalks a single brilliant light yellow flower-head. *H. spheculum* and *H. umbellatum* are tall weeds with uninteresting yellow flowers. Several others are more or less frequent, but can only be discriminated by the application of much patient care. *H. aurantiacum*, called Grim-the-collier, from the black hairs which clothe the flower-stalk and involucre, is an ornamental plant with orange flowers. The systematic name *Hieracium*, the English Hawkweed, the French *Epervire*, and the German *Habichtskraut*, all have reference to an ancient belief that birds of prey made use of the juice of these plants to strengthen their vision. [C. A. J.]

**HIEROCHLOA.** A genus of grasses belonging to the *Phalarida*, and consisting of several species spread over the colder parts of both hemispheres. They have loose spreading or narrow crowded panicles; three-flowered spikelets, the two lower flowers being males with three stamens, and the upper one smaller with two stamens and hermaphrodite; the glumes are scarious, boat-shaped, and pointed. One native species, *H. borealis*, found near Thurso, occurs in mountain pastures in Northern Europe, Asia, and America, and also in New Zealand. The name *Hierochloa*, sometimes written *Hierochloe*—whence Holy-grass—refers to the practice, adopted in some parts of Germany, of strewing it before the doors of churches on festival days. [T. M.]

**HIERONYMA.** *Elaginella*.

**HIGGINIA.** A genus of small Peruvian shrubs, belonging to the *Cinchonaceae*. The parts of the flower are arranged in fours; the corolla is somewhat bell-shaped, with a short tube, concealing the stamens within it; the ovary has two compartments; the ovules are numerous, the style short, and the stigma cleft and projecting. The fruit is berry-like, and two-celled. See CAMPHYLOBOTRYA. [M. T. M.]

**HIG-TAPER.** *Verbascum Thapsus*. The name is, according to Dr. Prior, often incorrectly spelt High-taper.

**HIGHWATER SHRUB.** An American name for *Iva*.

**HILFEROUS.** Bearing a hilum upon its surface.

**HILLIA.** The memory of Sir John Hill, a writer on various branches of botany, is held in little respect in this country, owing to some unseemly disputes with some of his contemporaries and with the Royal Society; nevertheless a genus of plants has been named in his honour, consisting of small tropical American shrubs reported to grow upon the trunks of trees, and belonging to the *Cinchonaceae*. They have somewhat fleshy leaves; an involucre of three or four bracts outside the calyx, the limb of which is divided into two to four narrow segments; a salver-shaped corolla, with a long tube, distended at the throat, and concealing four to six sessile anthers; a thread-like style, and thick stigma. The fruit is a long pod-like two-celled two-valved capsule, with numerous seeds which are provided with a loose integument prolonged at one end into a long brush-like appendage. [M. T. M.]

**HILUM.** The scar produced by the separation of a seed from its placenta. Also used to indicate any point of attachment; and the apertures in the exine of pollen grains.

**HIMANTHALIA.** A genus of olive-spired *Algae*, remarkable for the large immensely elongated forked receptacles, and the little cup-shaped frond which scarcely exceeds an inch in diameter. The plant is common on some parts of our coast, though rather local. The fronds when young sometimes become detached and form little bladders which make a loud report when trod upon. The only species, *H. lorea*, is known by the name of Sea-thongs from the strap-like appearance of the receptacles. The plant is biennial, the receptacle not being produced till the second year. It extends southward as far as Spain, but prefers rather cold waters. It is very rare, if found at all, on the coast of America. [M. J. B.]

**HIMANTHUS.** A Brazilian tree, constituting a genus of *Cinchonaceae*. Its flowers are arranged in spikes which are covered by a large spathe-like bract, falling off before the flowers expand. The parts of the flower are arranged in fives; the corolla is very long and funnel-shaped, concealing within it the stamens; the style is somewhat club-shaped; and the ovary has two compartments. The fruit is unknown. [M. T. M.]

**HIMERANTHUS.** A genus of *Solanaceae*. The flowers are placed singly on long stalks, and have a bell-shaped corolla, to the base of which, internally, the stamens with strap-shaped filaments are attached. The ovary is two-celled, the fruit fleshy, many-seeded, supported by the persistent calyx. It is found in Uruguay; and it is singular that a plant so nearly allied to

the true mandrake should be supposed by the natives of that country to possess the same power of exciting the passions as was attributed to the mandrake, in Greece &c., by the ancients, and even by mediæval writers. [M. T. M.]

**HINA.** The Pacific Island name for a Gourd.

**HINAU, or HINO.** *Eleocarpus Hinau*, the bark of which is used for dyeing in New Zealand.

**HINDA.** An Indian name for the Wild Date, *Phoenix sylvestris*.

**HINDBERRY.** *Rubus Idaeus*.

**HINDHEAL.** *Chenopodium Botrys*.

**HINDSIA.** A genus of cinchonaceous shrubs, natives of Brazil. The flowers have a calyx with unequal linear segments, sometimes dilated in a leaf-like manner; a funnel-shaped corolla with a long tube, somewhat dilated at the upper part; anthers on very short stalks at the top of the tube of the corolla; and a style divided at its upper part into two long linear compressed hairy branches. The capsule bursts by two valves, and contains numerous seeds. *H. violacea* is a stove plant of great beauty, with large deep blue flowers. [M. T. M.]

**HING.** The Indian name for *Asafœtida*.

**HINOID.** When veins proceed entirely from the midrib of a leaf, and are parallel and undivided; as in ginger-worts.

**HIP-TREE.** *Rosa canina*, the fruits of which are called Hips.

**HIPWORT.** *Cotyledon Umbilicus*.

**HIPPEASTRUM.** The Knight's Star Lily, a genus of *Amaryllidaceae*, consisting of South American and West Indian bulbs, remarkable for their showy flowers, and comprising most of the plants cultivated in hothouses under the name of *Amaryllis*, these being for the most part hybrids, which are very freely produced in the genus. The leaves, which are vernal, are bifarious, and precede or accompany the flowers; the latter usually grow several together at the top of a hollow scape, and are large and in most cases very handsome, the somewhat funnel-shaped declinate perianth having an abbreviated and narrow-mouthed tube with the faucial membrane deficient on the lower side; and a very irregular limb, the upper sepaline being wider, and the lower petaline narrower than the other segments. The filaments are declinate, curved, unequal, and unequally inserted into the throat; and the style is three-lobed or three-cleft. The flowers of some of the species, as *aulicum*, *equestris*, and *regium*, are crimson, scarlet, or orange-red, with a green star; of *vitatum* white striped with red; and of *reticulatum* purplish-red, beautifully veined with deeper red, and with a white central star. [T. M.]

**HIPPPIA.** A genus of South African

*Compositæ*, consisting of slender herbs or small branching shrubs, with leaves and flower-heads something like chamomile. The leaves are pinnatifid; the flowers are minute yellow rayless, disposed in corymbs at the ends of the twigs, and not unlike those of *Artemisia*, to which the genus is allied. The outer florets have pistils only, the inner stamens; and the orbicular compressed achenes have slightly winged margins, and no pappus. [A. A. B.]

**HIPPOBROMUS** *alatus*, the only representative of a genus of *Sapindaceæ*, is a South African tree of considerable size, with alternate unequally-pinnate leaves, bearing in their axils short velvety clusters of small reddish flowers. The leaves are made up of four to six pairs of unequal-sided serrate leaflets; and the flowers are unisexual, the sterile with five sepals, five petals, and eight stamens, the fertile with a like calyx and corolla, and a few barren stamens surrounding a three-celled ovary tipped with a short style. The genus differs from *Sapindus*, in the petals being destitute of a scale or tuft of hairs on their inner surface, as well as in the round berried fruits the size of a pea accompanied by the remaining calyx. The colonial name of the tree is *Paardepis*. [A. A. B.]

**HIPPOCASTANÆÆ**. A group of hypogynous *Exogens*, forming a subdivision of the order *SAPINDACEÆ*: which see.

**HIPPOCRATEACEÆ**. A natural order of thalamifloral, dicotyledons, included in Lindley's rharnal alliance of perigynous *Exogens*. Shrubby plants with opposite simple leaves having deciduous stipules; sepals and petals five imbricate; stamens three monadelphous. Fruit either consisting of three-winged carpels, or baccate. The prominent character of the order is the ternary stamens, and pentamerous sepals and petals. The plants are chiefly natives of South America, but some are found in Africa and Asia. The nuts of *Hippocratea comosa* are oily and sweet. The fruit of *Tontelea pyriformis* is eaten in Sierra Leone. There are seven genera and about ninety species. Examples: *Hippocratea*, *Tontelea*, and *Salacia*. [J. H. B.]

**HIPPOCRATEA**. A genus of the small order *Hippocrateaceæ*, consisting of upwards of thirty species, the greater part natives of the tropics of the western hemisphere, the remainder found principally in Western Africa, India, and the island of Timor. They are climbing shrubs, with opposite entire or toothed usually smooth leaves, and panicles of small inconspicuous flowers, produced from the axils of the leaves, and characterized by the anthers of their stamens consisting of single cells, which burst open transversely. Their fruit also differs considerably from those of the allied genera, being composed of three (occasionally only one or two) separate flattened leathery carpels, which split down the middle into two halves when ripe, each half resembling in shape a little boat. [A. B.]

**HIPPOCREPIFORM**. Horseshoe-shaped.

**HIPPOCREPIS**. The Horseshoe Vetch, a genus of herbaceous or somewhat shrubby leguminous plants, so called from the peculiar form of their seed-vessels, which are long and jointed, each joint being one-seeded and curved into a shape somewhat resembling that of a horseshoe. In all the species the leaves are pinnate, with a terminal leaflet. The flowers are yellow, in some species solitary in the axils of the leaves, but more frequently collected into simple umbels on slender axillary stalks. The only British species, *H. comosa*, is a low trailing plant with much of the habit of the common bird's-foot trefoil, but differs both in the shape of its leaves and pods. It is not uncommon on sunny banks of chalk or limestone. Several other species, some of which are annuals, inhabit the south of Europe. French, *Hippocrépe*; German, *Hufeisenpflanze*. [C. A. J.]

**HIPPOMANE**. The poisonous Manchineel or Manzanillo tree of tropical South America (*Hippomane Mancinella*) is the only species of this genus of Spurge-worts (*Euphorbiaceæ*). It forms a tree forty or fifty feet high, common in many of the West Indian Islands and in Venezuela and Panama, usually growing on sandy sea-shores. Its leaves are stalked, shining green, egg-shaped or elliptical, with the edges cut into saw-like teeth, having a single gland on the upper side at the junction of the stalk and leaf. Its flowers are very small and inconspicuous, and of separate sexes, borne on long slender spikes, the females few placed singly at the base of the spike, the males in little clusters occupying the upper part. The calyx of the males is two-parted, and that of the females three-parted, the male containing two or four stamens joined together by their filaments, and the females a many-celled ovary, crowned with from four to eight styles and reflexed stigmas. Its fruit is a roundish fleshy yellowish-green berry.

The virulent nature of the juice of the Manchineel tree has given rise, in the western hemisphere, to nearly as wonderful stories as those associated with the upas tree in the eastern; but although there can be no doubt that it possesses extremely poisonous properties, its powers have been greatly exaggerated, and many of the tales must be regarded as fabulous. Among the statements referable to the latter class may be included the assertions that grass will not grow under it, that mere sleeping in its shade causes death, that its juice raises blisters difficult to heal when applied to the skin, and others of a like nature. It is certain, however, that the juice, which resembles pure white milk, does possess a considerable amount of acidity, and that some persons suffer great pain from incautiously handling it, while others again do not experience the slightest inconvenience from it, its effects, as in the case of the poisonous *Rhus* of North America, depending upon peculiarities in the constitutions of different individuals. Perhaps its most dangerous

property is that of causing blindness, if by chance the least drop of the milk, or the smoke of the burning wood, comes in contact with the eyes. Dr. Seemann, in his *Narrative of the Voyage of H.M.S. Herald*, states that at Veraguas some of the ship's carpenters were blinded for several days from the jaloe getting into their eyes whilst cutting down Manchineel trees; while he himself suffered temporary loss of sight from merely gathering specimens; and that the same accident happened to a boat's crew from using the wood for making a fire. Salt water is said to be an efficacious remedy. The fruit also abounds in a similar acrid milky juice, and, from its tempting appearance, is sometimes bitten by those who are unaware of its deleterious properties, but its burning effect upon the lips soon causes them to desist. It is commonly asserted that the Indians use the juice for poisoning the barbs of their arrows, but, from its excessively volatile nature, this is improbable. [A. S.]

*Hippomane Manchineella.*

**HIPPOPHAE.** A shrub or low tree of the order *Elagnaceae*, distinguished by bearing the male flowers (with four stamens) in cactins, and the female in the axils of the leaves, on separate plants; the calyx tubular, finally assuming the character of a berry containing a single seed. *H. rhamnoides*, Sea Buckthorn or Sallow Thorn, is a native of many parts of the coast of Europe, including England, preferring a sandy soil, but sometimes found on the cliffs. In its native haunts it is usually a thick bush with numerous branches terminating each in a thorn. The leaves are narrow, of a peculiar leaden green above, silvery and scaly below. The berries, which are produced in great abundance, are yellow and of an acid flavour. The Tartars, it is said, make a jelly of them, and the fishermen of the Gulf of Bothnia prepare from them a fish-sauce, but in England they appear to be neglected. French, *Argousier*; German, *Haftdorn*. [C. A. J.]

**HIPPURIDAE.** A natural group de-

scribed by Link, now included under *HALORAGACEAE*; which see.

**HIPPURIS.** Aquatic herbaceous plants with whorls of narrow leaves, and inconspicuous flowers (also in whorls) of very simple structure. There are only two or three species, all much alike. They grow either wholly or partially submerged in ditches and canals, sending up from their creeping roots numerous unbranched erect stems, having at short intervals whorls of linear leaves, in the axils of which are the small inconspicuous flowers, each of which contains a single stamen, but no petals, and an ovary with a single seed. The most abundant species is *H. vulgaris*, the common Mare's tail, plentiful not only in Great Britain, but throughout Europe and North America. There is some resemblance in habit between these plants and *Equisetum*, but in all essential characters they are perfectly distinct. French, *Pesse d'eau*; German, *Schafthalm*. [C. A. J.]

**HIPTAGE.** A genus of climbing shrubs belonging to the *Malpighiaceae*. The flowers have a calyx provided with one large gland; unequal fringed petals; ten stamens, all fertile, and one larger than the rest; one style; and a fruit of three or fewer carpels, each provided with three wings. They are of a white or yellowish colour, and are fragrant. [M. T. M.]

**HIRÆA.** A genus of *Malpighiaceae*, distinguished chiefly by its ten stamens, all of which are fertile and slightly united at the base; by its three styles compressed at their summits, with truncate two-coloured stigmas; and by its fruits with lateral wings. [M. T. M.]

**HIRCINOUS.** Smelling like a goat.

**HIRONDAIRE.** (Fr.) *Vincetoxicum officinale*.

**HIRSE.** A kind of *Panicum* or Millet.

**HIRSUTE, HIRTUS.** Hairy; covered by long tolerably distinct hairs.

**HIRTELLA.** A genus of tropical American shrubs or small trees, of the order *Chrysobalanaceae*, differing from its allies in its five-petaled flowers with from three to fifteen long protruding stamens arising from one side of the flower. Upwards of thirty species are known, all of them with alternate shortly-stalked leaves accompanied by stipules; the flowers small, white or purplish, disposed in axillary or terminal racemes, and remarkable for their protruding stamens, which are usually much longer than the corollas. The fruits are pear-shaped furrowed drupes nearly an inch long, with one seed. *H. silicea* is a tree of Trinidad, where its bark, which is rich in siliceous matter, is said by M. Cruger to be used by the Indians in making pottery. *H. physophora*, a Brazilian species, is exceptional, in having on each side of the short leafstalks a leaty bladder-like process as large as a good-sized pea, with an opening at top. [A. A. B.]

**HISINGER.** *Xyloema*.

**HISPID.** Covered with long stiff hairs.

**HITCHENIA.** A genus of Indian herbaceous plants of the order *Zingiberaceae*. They have tuberiform rootlets; a stem destitute of leaves at its upper part, a spicate inflorescence, with white flowers, having a tubular three-toothed calyx, a corolla with a long slender tube, and a somewhat two-lipped limb, a short filament, channelled to receive the thread-like style, which is surmounted by a funnel-shaped stigma. The capsule is membranous, three-valved, and contains a number of seeds provided with a large star-like arillus. [M. T. M.]

**HOCHSTETTERIA.** A genus of *Compositae*, represented by *H. Schimperii*, a much-branched herb found in Arabia Petrea and Scind, whose wiry stems are furnished with distant serrated leaves, and each twig is terminated by a single orange-coloured flower-head. The genus differs from its allies of the fleabane group, in the florets being all tubular, perfect, and seated on a frilled receptacle. [A. A. B.]

**HOCK-HERB.** *Aithya*; also *Malva*.

**HOCKINIA.** An annual gentianaceous plant of Brazil. The flowers are blue, with a five-parted cylindrical calyx, a bell-funnel-shaped corolla, five stamens having the connective prolonged into a lance-shaped point, and a hairy stigma divided into two plates. The fruit is capsular, bursting by two valves. [M. T. M.]

**HODGSONIA.** A magnificent cucurbitaceous plant, very common in many parts of Eastern Bengal. The stems are described by Dr. Hooker as slender, frequently one hundred feet long, climbing the forest trees, and having their branching ends matted together and covered with leaves, which sometimes form a dense hanging screen of bright green foliage. The large flowers, yellow outside and white inside, remarkable for the long filiform twisted appendages hanging from their lobes, appear in May, and are very deciduous; they may often be seen strewing the ground in abundance in the forest, when the plant itself cannot be recognised amidst the canopy of vegetation above the traveller's head. The great melon-like fruit, called Kathior-pot by the Lepchas, ripens in autumn and winter. Its coarse hard green pulp exudes a gummy fluid in great abundance, but is austere and uneatable.

**HOFFMANNIA.** The name of a West Indian cinchonaceous herb, with hairy branches, ovate rough leaves, and axillary many-flowered peduncles. The parts of the flower are in fours; the corolla salver-shaped; the anthers sessile; the stigma blunt on the end of a simple style; the fruit two-celled, many-seeded. [M. T. M.]

**HOFFMANSEGGIA.** A genus of *Leguminosae*, nearly related to *Cassia*, but differing from it in the calyx segments being united by their margins so as to form a

five-toothed cup. It consists of about fifteen species distributed over California, and the temperate parts of Peru and Chili, two being peculiar to South Africa. They are neat little perennials, with bipinnate leaves often marked with black dots; and the pretty yellow flowers are arranged in racemes which arise from opposite the leaves. [A. A. B.]

**HOFMEISTERELLA** *sumicrescopica* is a little epiphytall orchid of Peru, belonging to the *Vandee*, nearly related to *Tetipogon*, and remarkable for the very long beak hanging down in front of the stigma. The plant is stemless, with a few fleshy roots, a tuft of lance-shaped leaves, and a short flexuous spike bearing a few small yellow flowers. [A. A. B.]

**HOGMEAT.** *Boerhaavia decumbens*.

**HOGWEED.** *Hieracium Sphondylium*; also *Polygonum aviculare*, and *Boerhaavia*. —, **POISONOUS.** *Aristolochia grandiflora*.

**HOENACKERIA.** A genus of umbellifers characterised by having the styles awl-shaped and bent back, and the fruit compressed laterally, somewhat pear-shaped, and having a cylindrical beak crowned by the five persistent sharp teeth of the calyx; each half of the fruit has five obtuse strong ridges and narrow grooves between. [There are two species natives of Southern Spain, Algeria, and the Caucasian region, dwarf annual rigid herbs densely dichotomously branched from the base, with linear entire leaves, and small greenish flowers.] [G. D.]

**HOENBERGIA.** A genus of Brazilian bromeliaceous herbs, distinguished from *Bilbergia* and other genera by the perianth, the outer segments of which are unequal, the two posterior segments being somewhat pyramidal winged and keeled, the anterior one convex outwardly and shorter; while the inner segments are longer, petal-like, occasionally provided with a minute scale at the base, and ultimately spirally twisted, as also are the three linear stigmas. [M. T. M.]

**HOITZIA.** A genus of *Polemoniaceae*, containing seven species, natives of Mexico. They are rigid or herbaceous undershrubs with alternate leaves, and axillary flowers crowded at the tops of the branches, with many bracts below the calyx. The calyx is tubular and five-cleft; the corolla funnel-shaped, with the limb divided into five unequal lacinae, and the stamens exserted. There are but few ovules in each of the three cells of the ovary. [W. C.]

**HOLACANTHA.** A name expressive of the thorny character of the shrub to which it is applied, and which forms a genus of *Simarubaceae*. It is a native of the deserts of Mexico and California, has no leaves, but is beset with strong spines. The flowers are small and unisexual, with a seven or eight-parted calyx, and seven or eight petals. [M. T. M.]

**HOLARRHENA.** A genus of dogbanes,

having the calyx in five deep divisions, which are very narrow and acute; and five stamens attached to the lower part of the tube of the corolla, their anthers perfect. The species are Indian shrubs, erect and smooth; the leaves opposite, stalked and of thin texture; the flowers in terminal and lateral bunches. [G. D.]

**HOLBOELLIA.** A small genus of *Lardisabalaceae*, consisting of scandent shrubs, natives of India, and having digitate leaves, and axillary corymbiform racemes of purple or greenish flowers, which are monocious, with six petaloid sepals and six minute petals. In the male flowers there are six free fertile stamens, and in the female six small sterile ones and three ovaries, which become oblong indehiscent berries. [T. M.]

**HOLCOSORUS.** A peculiar Bornean fern, referred by some botanists to *Grammitis* and *Polypodium*, but by others considered to form a distinct genus of the *Ternstroemia*. The fronds are solid and bluntly pentangular, with three grooves on the upper and two on the lower surface, the oval-oblong naked sort lying in the latter. The venation is reduced to a simple costa, imbedded in the centre of the — wiry fronds. *H. pentagonus* is the *Grammitis bidentata* of Hooker. [T. M.]

**HOLCUS.** A genus of grasses, mostly European, belonging to the tribe *Phalaraceae*, and distinguished by its somewhat open panicle with numerous crowded two-flowered spikelets. The upper flower is male, and has a shortly-awned glume, and the lower one is hermaphrodite, with the glume usually awnless. The outer glumes are boat-shaped, enclosing the flowers. Two species are natives of Britain; but they have soft woolly herbage, and are of little value. [T. M.]

**HOLEWORT.** *Corydalis bulbosa*.

**HOLIGARNA.** A genus of lofty Indian trees, belonging to the *Anacardiaceae*, and distinguished by the parts of the flower being arranged in fives; the petals oblong, hairy, spreading, attached to the five-toothed calyx; the ovary united to the tube of the calyx, and containing a single ovule at its upper part; and the fruit fleshy, with a one-seeded stone. From the stem of *H. longifolia*, a lofty tree, occasionally cultivated in our stoves, the natives of Malacca are said to extract an acrid juice, which is used as a varnish. The stone of the fruit likewise contains an acrid resinous juice, while the investing pulp contains a glutinous fluid made use of by painters, and for fixing colours on linen. The fruit and the bark are used medicinally, but require to be employed with caution, as they are apt to give rise to dangerous symptoms. [M. T. M.]

**HOLLOWROOT.** *Adoxa Moschatellina*.

**HOLLOWWORT.** *Corydalis bulbosa*.

**HOLLY.** *Ilex*. — **CAPE.** *Crocozydon*.  
**KNEE.** *Ruscus aculeatus*.

—, **MOUNTAIN.** *Nemopanthes*. —, **SEA.** *Eryngium maritimum*.

**HOLLYHOCK.** *Althaea rosea*, *chinensis*, and *scifolia*. Sometimes written Holli-hock, or Holy Hock.

**HOLLYWORTS.** Lindley's name for the *Aquifoliaceae*.

**HOLM.** The Holly, *Ilex Aquifolium*. —, **KNEE.** *Ruscus aculeatus*. —, **SEA.** *Eryngium maritimum*.

**HOLOGRAPHIS.** A genus of *Acanthaceae*, containing a single Mexican species, a branching undershrub, with oblong-ovate obtuse leaves, and axillary flowers in pairs. The calyx is equally five-parted, and the corolla ringent, with a very short tube. It has four didynamous stamens. [W. C.]

**HOLOLACHNE soongarica** is a plant of the *Reaumuria* family, which grows in saline places on the shores of lakes in Soongaria and Mongolia. It is a few inches high, much-branched, with white wiry stems furnished with numerous minute linear clustered fleshy leaves, bearing inconspicuous white flowers in their axils. The few (eight to ten) stamens, and the absence of scales at the base of the petals, are the chief characters. [A. A. B.]

**HOLOSERICEOUS.** Silky; so covered with hairs that it feels soft to the touch, although the naked eye may fail to detect the presence of hairs.

**HOLOSTEMMA.** A small genus of *Acletoadaceae*, from tropical Asia, consisting of twiners with largish flowers, deeply coloured inside and arranged in shortly pedunculate interpetiolar umbels or racemes. The corolla is rotate with a short tube, and the limb divided into five broadly ovate lobes. [W. C.]

**HOLOSTEUM.** A small genus of *Caryophyllaceae*, with the styles usually three and the capsule valves twice as many. They are small annuals found in Europe, North Africa, and temperate Asia, with simple stems, smooth oblong leaves in pairs, sometimes united at the base, and terminal umbels of small chickweed-like flowers. *H. umbellatum* is found in a few of the eastern counties of England, but is far from common. [J. T. S.]

**HOLY GHOST.** *Angelica sylvestris*.  
**FLOWER.** *Peristeris elata*.

**HOLY-HERB.** *Verbena officinalis*.

**HOLY-ROPE.** *Eupatorium cannabinum*.

**HOMALIACEAE.** (*Homaliads*). A natural order of monochlamydeous dicotyledons included in Lindley's catcal alliance of epigynous Exogens. Trees or shrubs with alternate leaves; perianth funnel-shaped, with five to fifteen gland-bearing divisions and alternating petaloid scales, the latter considered by some as petals, and hence Lindley places the order between *Loasaceae* and *Cactaceae*; stamens inserted on the perianth, either singly or in bundles of three or six; ovary adherent, one-celled; ovules

numerous, pendulous; placentas three to five parietal; styles three to five; fruit a capsule or berry; seeds albuminous. Tropical plants of India, Africa, and America, having astringent qualities. There are nine known genera and thirty-six species. Examples: *Homalium*, *Blackwellia*, *Nia*, *Cordylanthus*. [J. H. B.]

**HOMALIUM.** Tropical trees and shrubs, forming the typical genus of *Homaliaceae*. The principal characters reside in the stamens, which vary in number, and are attached to the perianth in groups of three or four placed opposite to the inner segments of the perianth, and alternate with fleshy glands placed in front of the outer or calycine segments; and in the capsule, which is one-celled, containing a few seeds and opening partially by three valves. The roots of some of the species are astringent. See *SAMYDACEÆ*. [M. T. M.]

**HOMALONEMA.** A genus of *Araceæ*, consisting of Indian herbaceous plants, with heart or arrow-shaped leaves; an expanded aromatic spathe; a spadix covered with flowers over the whole of its surface, and having rudimentary flowers mixed with the ovaries; numerous sessile anthers, and three-celled detached ovaries; and a three-cleft stigma. *H. cordatum*, with a white spathe, is cultivated in green-houses. *H. aromaticum*, a native of Chittagong, has an agreeable aromatic smell, and its root is deemed by the natives to possess medicinal virtues. [M. T. M.]

**HOMBAC D'ARABIE.** (Fr.) *Sodada decidua*.

**HOMBRONTIA.** A name given to two species of *Pandanus*, figured in the *Voyage de la Bonite*, but not yet described.

**HOMERIA.** The name of a few species of Cape bulb-tuberous plants, sometimes separated from *Moraea*, from which they differ in having nearly regular flowers. The perianth has a very short tube, and six divisions, of which the three alternate or inner ones are rather but not conspicuously smaller than the others, the three stamens are monadelphous, and the stigma is trifid, with two-cleft fringed branches. They are rather handsome plants, with linear-ensiform leaves, and leafy branching scapes bearing several showy enduring flowers, usually orange-red, copper-coloured, or yellow. [T. M.]

**HOMINY.** A meal prepared from Indian corn.

**HOMOCARPOUS.** Having all the fruits of a flower-head exactly alike.

**HOMODROMAL.** Having all the spires turned the same way; or the spires of a lateral organ the same as those on a central organ.

**HOMOGAMOUS.** When all the florets of a capitulum, &c., are hermaphrodite.

**HOMOGENS.** A name given by Lindley to a division of *Exogens* characterised by the wood being arranged in the form of

wedges, and not in concentric circles or zones. It is seen in the case of *Piperaceæ*, the shrubby *Aristolochiaceæ*, *Nepenthaeæ*, *Lardizabalaceæ*, and *Menispermaceæ*. The term is not now used. [J. H. B.]

**HOMOZYNE.** A small genus of stemless composite herbs, found in Alpine situations in South Europe. They have long stalked root-leaves with kidney-shaped toothed or angled blades, and flower-scapes three inches to a foot in length, furnished with one or two distant leaves, and terminating in a single white or purple flower-head, having all the florets tubular. Related to *Petasites*, they differ in the heads being solitary instead of numerous on each scape. *H. alpina* and *H. discolor* are sometimes seen in collections of Alpine plants. [A. A. B.]

**HOMOTIOS, or HOMO.** In Greek compounds = alike or similar.

**HOMOLOGUE.** Organs are called homologous when they have the same analytical relations, or, in other words, correspondence of structure and origin, though the functions may be different; analogous when they resemble each other in outward form or in functions. Affinity, on the contrary, expresses a close relation of one species, genus, or order to another. The several external parts of a water-lily, for instance, are perfectly homologous with those of a common white lily, but there is no affinity between them. Pollen-grains and the spores of many of the higher cryptogams resemble each other in origin and germination. They are, therefore, homologous with each other, though their functions are totally different. [M. J. B.]

**HOMOMORPHUS.** Uniform. All shaped alike.

**HOMONEMEÆ.** A name given by Fries to the lower cryptogams as propagated by spores which send out threads of the same nature with the perfect plant, and do not produce anything like a false cotyledon as in ferns. [M. J. B.]

**HOMORANTHUS.** An Australian genus of *Chamaeliaceæ* represented by one species, *H. virgatus*, a spreading or diffuse shrub, closely resembling *Darwinia bazillota* in aspect, and only differing from that genus in the subulate calyx-lobes. The flowers are nearly sessile, growing two to four together, at the ends of the branches, with four entire petals, shorter than the calyx-lobes, and ten stamens. [J. Br.]

**HOMORGANA.** A term applied to cryptogamic plants, as consisting of cells only, without vessels. It is synonymous with *Cellulares*, and is liable to the same objections. [M. J. B.]

**HOMOTHALAMUS.** Resembling the thallus; a term employed among lichens only.

**HOMOTROPAL.** Having the same direction as the seed, but not straight.

**HONAY.** An Indian name for *Calophyllum Inophyllum*.

**HONESTY.** *Lunaria biennis*.

**HONEWORT.** *Silene Amomum*; also *Trinia vulgaris*, and *Cryptotania canadensis*.

**HONEYBERRY.** The name in modern Greece of the berries of *Celtis australis* also *Melicocca bijuga*.

**HONEYDEW.** A sugary secretion from the leaves of plants in hot weather, usually attributed to aphides, because they secrete a similar matter. When the secretion is extreme, as is sometimes the case in unusual heat, it drips from the leaves in little drops, which are sometimes so abundant that they may be swept up in considerable quantities. The secretion is then called Manna, though it is not intended by the term to identify it with the manna of the ash. The affection is ranked in vegetable pathology under the genus Apostaxis, and is generally harmless. [M. J. B.]

**HONEY-FLOWER, or HONEY-PLANT.** *Melanthus*.

**HONEYSUCKLE.** *Lonicera*; also applied amongst agriculturists to meadow clover, *Trifolium pratense*. — of Australia. *Banksia serrata*. — of Jamaica. *Passiflora laurifolia*. —, BUSH. *Dicrvillea*. —, DWARF. *Cornus suecica*. —, FLY. *Halimolobos*; also *Lonicera xylosteum*. —, FRENCH. *Hedysarum coronarium*. —, HEATH. *Banksia serrata*. —, WHITE *Azalea viscosa*.

**HONEYSUCKLE TREE.** *Banksia australis*.

**HONEYWARE.** *Alaria esculenta*; also *Laminaria saccharina*.

**HONEYWORT.** *Ceranthium*.

**HONGHEL-BUSH.** *Adenium Honghel*.

**HONKENYA, or HONKENEJA.** A genus of *Caryophyllaceae*, allied to *Alsine*, but distinguished by its few large pear-shaped seeds, beaked at the end and having an indentation on the opposite side. They are all littoral plants found in the northern hemisphere, in the temperate and arctic zones. *H. peplioides* is very common on the shores of the British Islands, its rhizome creeping in the sand. [Benth and Hooker make it a synonym of *Ammodenia*, a subgenus of *Arenaria*.] [J. T. S.]

**HOODED.** The same as Cucullate.

**HOODIA.** A remarkable genus of *Asclepiadaceae*, containing two branching South African herbs, with fleshy many-angled cactus-like stems, thickly covered at the angles with strong prickles, which are dilated at the base. The flowers have a very large corolla, and are on short peduncles near the apex of the stem; the calyx five-parted; the corolla rotate with a very short tube and a large dilated faintly five-lobed limb, each lobe terminating in an aristate tooth. The staminal crown is double, the outer whorl consisting of five deeply emarginate lobes, with the margins

incurved, the inner of five alternating leaflets bent downwards. [W. C.]

**HOOKE-BACK.** Curved in a direction from the apex to the base; as the side lobes of the leaf of the dandelion.

**HOOKERIEI.** A natural order of mosses, distinguished by the flat creeping irregularly-branched stems, with reticulated leaves, a cernuous succulent capsule on a succulent elongated footstalk, a campanulate smooth veil and double peristome. *Hookeria lucens* is one of our most beautiful mosses, and remarkable for its large pale shining loosely reticulated leaves. It is not uncommon in Devonshire. Most of the species are extra-European, and inhabitants of warm regions. A few have not flattened stems, and two or three species included in the Antarctic Flora have erect capsules, but these are distinguished from *Leucodon* by their mitriform veil. Occasionally the base of the veil is laciniate, as in the Irish *H. latevirens*. [M. J. B.]

**HOOKHEAL.** *Prunella vulgaris*.

**HOOP-PETTICOAT.** *Corbularia*.

**HOP.** *Humulus Lupulus*. —, WILD. *Eryonia dioica*.

**HOPEA.** A genus of *Dipterocarpaceae*, consisting of resin-bearing trees natives of Borneo, whose flowers differ from those of *Shorea* only in the number and disposition of the stamens. [M. T. M.]

**HOPKIRKIA.** A genus of *Compositae*, peculiar to Mexico, represented by a single species, *H. anthemoides*, a smooth branching herb, with pinnately-parted leaves, and small terminal flower-heads with yellow florets. The involucre consists of four or five obovate scales, and encloses three tubular four or five-toothed florets, whose silky achenes are crowned with a pappus of eight chaffy one-nerved scales, three-toothed at top, the nerve prolonged into an awn. [A. A. B.]

**HOPPIA.** A small genus of Brazilian cyperaceous plants, belonging to the tribe *Cariciniæ*. The inflorescence is in heads which are composed of compound imbricated spikes. [D. M.]

**HORANINOVIA.** A genus of *Chenopodiaceae* closely allied to *Ailsoia*, but differing in habit, and in the perianth being longer than the filaments, in the segments having a smaller wing not produced till much later, after flowering, and in the minute styles looking like a simple stigma. They are rough annual herbs of temperate Asia. [J. T. S.]

**HORARIOUS.** Enduring for an hour or two only; as the petals of *Cistus*.

**HORDEUM.** The Barley: one of the most valuable of the genera of grasses (*Graminaceae*). As a corn plant, Barley is perhaps one of the most early cultivated, and its different varieties can be grown under a wider range of climatal differences than

almost any other variety of cereal; but which wild species is the true parent of the cultivated form is a matter involved in obscurity, though in all probability one of the wild forms of the more temperate parts of India may be made to yield a good grain by cultivation. The genus may be distinguished by its spikelets being in threes arranged on opposite sides of the rachis, hence forming a bilateral spike.

The species consist of—1. Cereal Barleys: *H. hexastichum*, the six-rowed, in which all three flowers of the spikelets are perfect and fertile; *H. distichum*, the two-rowed, in which only the central flower is fertile, and the two lateral abortive. 2. Wild Barleys: *H. murinum*, *pratense*, and *maritimum*.

Of the many varieties of cultivated Barley, those known as distichous or two-rowed Barley are those more commonly cultivated, for in them the seed is tolerably uniform in size, and so a better sample is produced, and we believe that it is even more productive than the six-rowed form. This latter, however, is frequently attempted to be employed in farming; but as the lateral flowers are seldom so plump as the central one, a very uneven sample is the result. This is one of the causes of the greater coarseness of the varieties of the six-rowed barley when compared with the two-rowed—a fact perhaps more observable in the black variety than in any other.

In this group we must notice a naked six-rowed variety, the grain of which separates from the chaff scales after the manner of wheat: the difference being that in ordinary barley we have the grain + the chaff scales, which adhere and form what is usually called the skin of the barley, which is described as coarse or fine according to its degree of thickness: whilst in the naked barley we have the grain—the chaff scales. This latter is not a good malting kind, and therefore, though interesting from a botanical point of view, is never likely to become extensively cultivated.

Of the Meadow Barleys, *H. pratense* only is of any importance. Its herbage is sweet and nutritious, and when the field is constantly depastured it is an exceedingly good species to encourage; but its long awns, rough as they are with little spiculae or projections for their whole length, render them highly prejudicial in hay, for being very brittle they readily break up into small lengths which stick beneath the tongue or in the gums, the spiculae acting like barbs in preventing their removal, and so creating great irritation, swelling of the mouth, and inability to eat, which often result in serious derangements to the animals partaking of it. This effect would be even more conspicuous if the Wall Barley, *H. murinum*, formed part of a meadow, but it particularly affects old walls and waste places. Still, however, it is not unfrequently occurs in waste corners of sandy fields, and when this is so the contents of such spots should never be included in the hay-rick. We all remember how in our youth we put inverted spikes of the Wall Barley

up our sleeves and found them travel to our shoulders, where they were difficult to dislodge without disarranging them. This was caused by the parts of the spikelets being compressible, so that by a gentle motion they progressed upwards with a kind of spring; but the spiculae or barbs, on pulling the spike the contrary way, stuck into the clothes, and so it could not easily be dislodged from its position.

Both the Wall and the Seaside Barleys are denizens of sandy soils—the former everywhere, the latter on the seashore. The Wall Barley is thus a remarkable agrarian indicator of the nature of land. On the sands of the tertraries it is a common weed, so on the more sandy deposits of the new and old red sandstones. A curious instance of the partiality of this grass for sand occurs in the Cotswold hills; these are composed of oolitic freestones and chalk, both calcareous rocks, and there, as in the clays of the Oxford clay and lias, it is universally absent; but in the lias hollows of the valley of the Severn, as at Gloucester and Cheltenham in the former county, and Bredon in the latter, where are thick beds of sand varying to as much as thirty feet in depth, the wall barley so abounds, as to become a most exact indicator of the boundary lines of the arenaceous deposit. See CRITHO. [J. B.]

**HOREHOUND** *Marrubium vulgare*. —, BLACK. *Ballota nigra*. —, STINKING. *Ballota*. —, WATER. *Lycopus*. —, WHITE. *Marrubium*. —, WILD. *Eupatorium leucifolium*.

**HORESTRANG** *Peucedanum officinale*.

**HORKELIA**. A genus of the rose family peculiar to Oregon and California, and numbering about a dozen species. They are perennial herbs one to two feet high, with pinnatifid root-leaves, the stems terminating in crowded cymes of minute white or pink flowers. From *Potentilla* they differ in the small flowers, and in the definite number of stamens (ten in two series). [A. A. B.]

**HORMIDIUM**. A section of the genus *Epidendrum*.

**HORMIN**. (Fr.) *Salvia Horminum*.

**HORMINUM**. A small genus of labiate plants. The calyx is bell-shaped and two-lipped, the upper lip with three teeth, the lower with two; the tube of the corolla much longer than the calyx, and the corolla itself imperfectly two-lipped, the upper lip being very short and notched, the lower three-lobed. The anthers cohere in pairs. *H. pyrenaicum* is a tufted perennial herb, with numerous root-leaves, simple almost leafless stems, and purplish-blue flowers which grow in whorls of six, all turned the same way. It is a native of the temperate parts of Europe, on the mountains. [C. A. J.]

**HORMOGYNE**. A name applied to an Australian shrub belonging to the order *Sapotacea*. It may be recognised by the anthers, all of which burst inwardly; and

by the jointed ring which surmounts the ovary—whence the name, from *ornos*, a necklace. [M. T. M.]

**HORNBEAM.** *Carpinus Betulus*. —, **HOP.** *Ostrya vulgaris*.

**HORNEMANNIA** *pinnata* is a slender prostrate creeping Nepalese herb, with ovate pinnately divided leaves and small flowers, forming a genus of *Scrophulariaceae* nearly allied to *Sibthorpin*, and differing chiefly in the corolla, which is more distinctly contracted at the base into a short tube. The name *Hornemannia* had been previously applied to a species of *Thibaudia*, and to *Mazus rigosus*.

**HORN OF PLENTY.** *Fedia Cornucopiae*.

**HORN PLANT.** *Ecklonia buccinalis*.

**HORNSCHUCHIA.** A Brazilian genus of doubtful affinity, placed by Von Martius in the ebony family. *H. bryotrophe*, so called from the moss growing on its leaves, is said to be a scrambling shrub, with three to five-nerved oblong unequal-sided leaves, and small white flowers in racemes arising from the lower naked shoots, each flower with a cup-shaped nearly entire calyx, six petals, six stamens, and a three-celled ovary which develops into a fruit of three cylindrical carpels each about an inch long. [A. A. B.]

**HORNUS.** Anything the produce of the same year; thus *Rami horni* are branches not a year old.

**HORNWORT.** *Ceratophyllum*. Hornworts is Lindley's name for the *Ceratophyllaceae*.

**HORNY.** Hard and close in texture, but not brittle, as the albumen of many plants.

**HOROLOGIUM FLORÆ.** A time-paper of flowers; a table explaining the time at which the same flowers expand in different latitudes.

**HORSEBANE.** *Oenanthe Phellandrium*.

**HORSECHIRE.** *Teucrium Chamædrys*.

**HORSE-FLOWER.** *Melampyrum sylvaticum*.

**HORSEHEAL, or HORSHELE.** *Inula Helentium*.

**HORSEHOOF.** *Tussilago Farfara*.

**HORSEKNOB.** *Centaurea nigra*.

**HORSE-MUSHROOM.** A term commonly applied to the larger kinds of mushroom, as *Agaricus arvensis*, to the exclusion of the true pink-gilled *A. campestris*. Though the latter is doubtless the more delicate and makes the finest ketchup, the horse-mushroom need not be excluded on account of its supposed unwholesomeness. It is largely consumed in London and all our greater towns, and when eaten in moderation is an excellent article of food. The species is distinguished from *A. campestris* by its paler gills and generally double ring,

but especially by its turning yellow when bruised. A variety of this species, commonly known as the Hedge Mushroom, with a yellower scaly pileus, is an object of suspicion, as is also one which occurs in woods and has a bell-shaped pileus which instantly becomes of a deep yellow when touched. A closely allied species or variety is known by the name of Springers. It is observable that in Italy this species is considered far safer than the common mushroom. In France, also, it is highly esteemed, and is known under the name of *Boule de Neige*. [M. J. B.]

**HORSEPIPE.** *Equisetum*.

**HORSERADISH.** *Cochlearia Armoracia*.

**HORSERADISH-TREE.** *Moringa pterygosperma*.

**HORSETAIL.** *Equisetum*. —, **SIRUBBY.** *Ephedra*. — **TREE.** *Casuarina equisetifolia*.

**HORSEWEED.** *Erigeron canadense*; also *Collinsia*.

**HORSEWOOD, JAMAICA.** *Cullandra comosa*.

**HORSFIELDIA.** A genus of umbellifers having the fruit flat and covered with wool, each half of it with three ribs on the back. The genus was founded in honour of Dr. Horsfield, well known for his researches in the natural history of Java. [There are two species, Javanese prickly shrubs: *H. aculeata* having cordate three to five-lobed leaves, glabrous above; and *H. peltata*, with peltate palmate leaves, setose above.] The genus is of interest to the botanist, as in some measure connecting umbellifers and ivywarts, having the fruit of the former and the general habit of the latter. [G. D.]

**HORTENSIA.** (Fr.) *Hydrangea Hortensia*.

**HORTENSIS.** Of or belonging to a garden.

**HORTIA.** Three Brazilian shrubs forming a genus of *Rutaceae*. The flowers are arranged in a corymbose manner on thick stalks; they have a cup-shaped calyx; five lance-shaped petals much longer than the sepals, hairy at the base on their inner surface, and with their points turned inwards like a hook; five stamens inserted on a disk with the petals, the filaments glandular and flattened; and a thick style surmounting a five-lobed ovary. The fruit is a capsule with one or two-seeded compartments. *H. brasiliensis* is said to possess febrifugal properties. [M. T. M.]

**HORTONIA.** A genus of *Schizandraceae*, consisting of smooth shrubs with entire leaves, axillary cymose inflorescence, and pale yellow flowers. The sepals and petals number about thirty, in many rows; the stamens seven to ten, their filaments having two glands at their base. There are from fifteen to twenty ovaries, and the stigma is sessile. The fruit consists of dry closely-agglomerated drupes. Thero

is but one species, *H. floribunda*, found in Ceylon. [J. H. B.]

**HORTUS SICOUS.** The same as *Herbarium*.

**HOSACKIA.** A genus of pretty dwarf pea-flowered annual or perennial herbs, found in Oregon, California, and Mexico. Though allied to, and having much the appearance of, *Lotus*, they differ in the minute (not foliaceous) stipules. The leaves are in many species unequally pinnate, in others trifoliolate; the flowers are mostly yellow mixed with white and purple, usually disposed in umbels, which are often stalked. Upwards of twenty species are known. [A. A. B.]

**HOTTENTOT BREAD.** *Testudinaria Elephantipes*.

**HOTTONIA.** Aquatic herbaceous plants distinguished among the *Primulaceæ* by their capsules, which, when ripe, split into five valves connected at the base and summit. *H. palustris*, the Water Violet, is a singular and beautiful plant found in ditches and pools in many parts of England, and is not unfrequently cultivated. The roots are long and silvery, and are either suspended in the water or strike deep into the muddy bottom. The leaves, wholly submersed, are finely pinnated or pectinated, and grow in tufts, from the midst of which rises a long cylindrical solitary stalk, bearing a pyramid of handsome light purple and white flowers, which are disposed in whorls. French, *Plume d'eau*; German, *Wasserviole*. [C. A. J.]

**HOUBLON.** (Fr.) *Humulus*.

**HOULLETIA.** The name of a few epiphytal orchids of tropical America, having ovate or conical pseudobulbs with one long membranaceous plaited leaf at the apex, and from the base of the bulb erect or drooping spikes, ending in a raceme of rather large and handsome nodding flowers. In *H. Brocklehurstiana*, the erect flower-scape is a foot and a half high, and the individual flower two inches in diameter, and deliciously sweet; the sepals and petals spreading, nearly equal, yellow, mottled with blood-red; the lip purple at the apex, and furnished with two horn-like processes directed towards the column. The genus is related to *Stanhopea*, differing, according to Brongniart, in the spreading sepals and petals, and in the lip being articulate in the middle, with two horns on its lower half directed towards the column. It has been named after M. Houlet, a French gardener. [A. A. B.]

**HOUDSBERRY, or HOUNDSTREE.** The Dogwood, *Cornus sanguinea*.

**HOUDS-TONGUE.** *Cynoglossum officinale*.

**HOUCHE.** (Fr.) *Holcus*.

**HOUSELEEK.** *Sempervivum tectorum*.

**HOUSELEEK-TREE.** *Æonium arborescens*.

**HOUSTONIA.** *Hedyotis*.

**HOUTTEA.** One of the generic or sub-generic groups, separated from *GEANERA*: which see.

**HOUTTUYNIA.** A genus of marsh plants, inhabiting Japan and tropical Asia, and belonging to the *Saururaceæ*. They have a creeping jointed rhizome, a wavy herbaceous stem, heart-shaped leaves, with a large sheathing stipule above them, and flowers placed on a spike surrounded at its base by a ring of a few white bracts. Perianth none; stamens three, adherent for some distance to the ovary; fruit capsular, of three carpels, with three parietal placentas and numerous seeds. *H. cordata*, a curious and not inelegant plant, is occasionally met with in cultivation; its leaves are accounted serviceable as a medicine in Cochin China. [M. T. M.]

**HOUX.** (Fr.) *Ilex Aquifolium*. — **DE MAHON.** *Ilex balcanica*. — **FRAGON, FRÉLON, or PETIT.** *Ruscus aculeatus*.

**HOVE.** *Nepeta Glechoma*, sometimes called *Glechoma hederacea*.

**HOVEA.** A genus of handsome blue-flowered evergreen bushes, belonging to the *Leguminosæ*, differing from its allies in having turgid nearly orbicular pods as large as good-sized peas. Of about twenty known species, the greater part are confined to Western Australia, the rest occurring in South-eastern Australia and Tasmania. The leaves are mostly lance-shaped or linear, with the margins entire and rolled back, and both surfaces smooth, or the lower clothed with rusty down. *H. thicketia*, sometimes called *Plagiolobium thicketia*, has holly-like leaves. *H. Celsi* is one of the best known, and a very common and beautiful greenhouse plant, flowering like most of the species in spring. This plant exhibits the peculiarity of the flower-buds of the succeeding year appearing at the bases of those expanded during the present—a common condition of leaf-buds, but not frequently seen with flower-buds. The genus bears the name of M. Hove, a Polish botanist. [A. A. B.]

**HOVENIA.** A genus of *Rhamnaceæ*, nearly allied to *Ceanothus*, from which it is readily recognised by the short foot-stalks of the minute whitish flowers (which are in axillary or terminal forked panicles) becoming much thickened after the flower withers. [One species only is known, *H. dulcis*, which is distributed over China, Japan, and the Himalayas; the plant of the latter district has been called *H. inaequalis*.] It is a tree with alternate heart-shaped serrated leaves. The round fruits, about the size of a pea, are seated on the end of the recurved fleshy peduncle, which is cylindrical, about an inch long, and contains a sweet red pulp which is eaten. [A. A. B.]

**HOWARDIA.** A genus of trees or shrubs

inhabiting tropical America, belonging to the *Orobanchaceae*, and named in honour of Mr. Howard, an eminent English pharmacologist. The flowers are remarkable, in that one of the sepals of the calyx is expanded into a large heart-shaped stalked leaf. The corolla is tubular and hairy; the stamens originate from a densely hairy ring; the ovary is surmounted by a cushion-like disk; and the fruit is capsular, girt at the top by the remains of the calyx, and bursting from above downwards.

*H. (Chrysocylon) febrifuga* furnishes a bitter tonic bark, first detected by Mr. Howard, who likewise found that its medicinal qualities depended on two chemical principles, one an alkaloid called *howardina*, the other a bitter principle. With reference to the leafy calyx of these and some allied plants, as *Mussaenda*, &c., it may be remarked, that the arrangement of the veins of the leafy sepal is different from that of the true leaves, a fact which has, apparently, been generally overlooked. [M. T. M.]

**HOYA.** A genus of *Asclepiadaceae*, containing, besides one *Asclepias* species, a large number of species dispersed over tropical Asia. They are herbaceous plants with twining or creeping stems, which throw out roots at the lower nodes. The

*Hoya imperialis.*

leaves are opposite, often, but not in all the species, thick and fleshy; and the flowers are in lateral umbels. The corolla is rotate, the five lobes of the limb are ovate and valvate in the bud. The staminal corona consists of five scales inserted on the gynostegium, and usually spreading horizontally like a star in the centre of the corolla; the linear angle bears a small tooth incumbent on the anther. The pollen-masses are erect, oblong, and attached in pairs. The stigma is not beaked. The follicles are smooth or with wing-like appendages. The genus contains some of the most ornamental among the plants cultivated in our hothouses. [W. G.]

**HUACOSARO.** A Peruvian fern, *Elaphoglossum Ruizianum*.

**HUCKLEBERRY.** *Celtis crassifolia*.

**HUCKLEBERRY.** *Gaylussacia*.

**HUDSONIA.** A genus of North American *Cistaceae*, including three species, which are bushy little heath-like shrubs, seldom a foot high, covered all over with small awl-shaped or scale-like persistent downy leaves, producing numerous small but showy yellow flowers crowded along the upper part of the branches. The capsule is one-celled, two to six-seeded; the embryo is coiled into the form of a closed hook. [J. Br.]

**HUGELIA.** A genus of Californian annuals belonging to the *Polemoniaceae*, now united with *Gilia*, from which it is distinguished by having a short tube to the corolla, and linear arrow-shaped anthers. All the species are more or less clothed with white down, the leaves alternate, and the flowers disposed in heads surrounded at the base with dense wool. Some of the species have blue and yellow flowers.

The name has also been given to an Australian genus of *Rutaceae*, which is said to differ from its congeners in its ten-cleft calyx, its ten petals, and its indefinite perigynous stamens. [C. A. J.]

**HUGONIACEÆ.** A name given by Arnott to a group of plants now included under *Oxalidaceae*. [J. H. B.]

**HUGONIA.** A genus of *Oxalidaceae*, considered the type of a special order by Planchon and others. They are Indian shrubs, with alternate oval leathery leaves, and single-flowered axillary peduncles, often changed into a circinate spine. The flowers have the parts in fives, the stamens being twice as many. The fruit is a fleshy berry or drupe, with five pips. The roots of *H. Mysore* smell like violets, and are said to act on the kidneys and skin; they are used in reducing inflammation, and as a remedy for the bite of snakes. [J. T. S.]

**HUILE ANTIQUE DE LAVANDE.** (Fr.) A perfumery oil, forming one of the ingredients of Eau de Cologne. — **DE CADE.** A tarry oil obtained from *Juniperus Oxycedrus*. — **DE CÉDRAT.** An essential oil obtained from the citron. — **DES MARMOTTES.** An oil obtained from the kernel of *Prunus Brigantia*.

**HULDEE.** An Indian name for *Curcuma longa*.

**HULST.** *Rex Aquifolium*.

**HULVER.** *Rex Aquifolium*. —, **KNEE.** *Ruscus aculeatus*. —, **SEA.** *Eryngium maritimum*.

**HUMATA.** A small genus of creeping davallioïd ferns, sometimes referred indeed to *Davallia* itself, but having more of the technical character of *Cystopteris*. They are variable in character, having simple, lobed, pinnatifid, pedately pinnatifid, or subternate rigid leathery fronds. The sori, which are covered by suborbicular-reniform or transversely oblong reniform indusia, affixed only by their broad base, are usually vertical at the apex of the veins, but sublateral in *H. Gatmardiana*. The species are mostly

natives of India and the Indian and Eastern Islands, one of two being also found in the Mascaren Islands, and in the Feejees. [T. M.]

**HUMBERTIA.** A genus of *Convolvulaceae*, containing a single species from Madagascar. It is a tree with obovate petiolate leaves, and single-flowered peduncles. The calyx consists of five sepals, the corolla is five-cleft, the five stamens are much exserted, and the ovary is surmounted by a curved style, and a flat hollowed-out stigma. The baccate ligneous capsule is two-celled, with two seeds in each cell. [W. G.]

#### HUMBLE PLANT. *Mimosa pudica*.

**HUMBOLDTIA.** A genus of the *Cesalpiniæ* group of *Leguminosae*, consisting of two elegant scrambling shrubs, found in Malabar and Ceylon. They have curiously tumid branchlets, furnished with unequally-pinnate leaves, at the base of which are remarkable leaf-like stipules, transversely dilated at their point of attachment. The numerous scarlet flowers are disposed in axillary racemes, and have a four-toothed tubular calyx supported by two bracts, three or five petals and stamens, and an ovary which becomes an oblong compressed pod, with numerous seeds. From *Jonesia* it differs in the presence of petals, and from other allied genera in the nature of the stipules. The name of the illustrious Humboldt is perpetuated in the genus. [A. A. B.]

**HUMEA elegans**, so well known and so frequently cultivated in gardens, is the best known species of this genus, which belongs to the *Compositæ*, and is remarkable for its minute and extremely numerous flower-heads, each of which contains but three or four tubular and perfect florets. This plant, found in a wild state in Southeast Australia, is in our gardens an erect unbranched biennial, attaining a height of four to eight feet, the stems furnished below with ample dock-like leaves, and terminating in a beautiful pyramidal panicle, consisting of myriads of drooping rose-coloured heads, not much larger than the flowers of some grasses. The whole plant is somewhat glutinous, and, especially when bruised, emits a strong and peculiar balsamic odour. [A. A. B.]

**HUMIFUSE.** Spread over the surface of the ground.

**HUMILIS.** Low. When the stature of a plant is not particularly small, but much smaller than that of kindred species; thus, a tree twenty feet high may be called low, if the other species of its genus are forty or fifty feet high.

**HUMIRIACEÆ. (Humirids.)** A natural order of thalamifloral dicotyledons included in Lindley's erical alliance of hypogynous Exogens. Balsamic trees or shrubs with alternate simple exstipulate leaves; calyx in five divisions; petals five, imbricate; stamens numerous, monadelphous,

the anthers two-celled with a membranous connective, extended beyond the lobes; disk often present; ovary five-celled. Fruit a drupe; seed albuminous; embryo orthotropical. They are natives of tropical America. The genera are: *Yantanea*, *Humirium*, and *Saccoglottis*. [J. H. B.]

**HUMIRIUM.** This and two other genera of small trees or shrubs form the order *Humiraceæ*, all the species of which belong to tropical South America. *Humirium* is distinguished by its flowers being small and arranged in cymes; by their stamens being twenty in number, either all bearing a single anther, or, in a few species, five of them larger with three-forked filaments bearing three anthers; and by the disk being ten-lobed. About a dozen species are described.

*H. balsamiferum*, the Humiri of French Guiana, is a tree growing about forty feet high, and having smooth, egg-shaped or oval-oblong, stalkless leaves, with the base half clasping round the stem. It produces a red-coloured wood, useful for house-building; and its bark, when wounded, yields a reddish balsamic juice, possessing an odour like that of storax, and which after a time becomes hard and brittle, and is then burnt as a perfume. An ointment is also prepared from it, and used for pains in the joints, besides which it is given internally as a remedy for tape-worm and other complaints. *H. floribundum* is a small tree common in Brazil, where it is called 'Umire,' and its wood is used for the rafters of houses. Its bark is greatly esteemed as a perfume by the Brazilians, and when wounded a fragrant yellow balsam, termed balsam of Umiri, flows from it. [A. S.]

#### HUMMING-BIRD BUSH. *Psychotria montevidensis*.

**HUMULUS.** The common Hop (*H. Lupulus*), belonging to the *Cannabaceæ*, is the sole representative of this genus. It is a perennial, producing annually long, weak, roughish twining stems, and lobed coarsely-toothed leaves, which bear a general resemblance to those of the vine, but are harsh to the touch; each pair of leaves has two forked curved stipules between them. The male and female flowers are produced on separate plants. The males grow in loose, drooping panicles from the axils of the leaves, and have five sepals and five stamens; while the females form green scaly cones or catkins, which are produced either singly or in clusters, and are composed of a number of broad concave scales, partly overlapping, each having two inconspicuous flowers at its base. After flowering and during the period of ripening, these cones increase in size, and when full grown constitute the well known 'hops' used by brewers. The scales also become covered with small grains of a resinous substance, called *lupuline*; and the ovary changes into a small nut which is enveloped in the enlarged sepal, and is the true fruit.

The Hop was well known to the Romans, and is mentioned by Pliny under the name of *Lupulus sativarius*. It gradually spread through Europe during the middle ages, but was not cultivated in England till the year 1534, when it was introduced from Flanders, though not without violent opposition, petitions against it being presented to Parliament, in which it was stigmatised as 'a wicked weed that would spoil the drink, and endanger the people.' At the present day, the principal hop-producing countries are England, Belgium, Bavaria, and the United States. In England about 50,000 acres are devoted to it, chiefly in Kent, Sussex, Hampshire, Wiltshire, and Herefordshire, and more sparingly in Essex, Suffolk, Surrey, Yorkshire, &c. Several varieties are known, the finest of which are the White Bines, the Goldings, and the Grapes. The plants are supported during growth upon stout poles varying in height from ten to twenty feet. When the hop-picking season arrives, usually early in September, the stems are cut through at about a yard from the ground, and the poles pulled up, so that the hops may readily be picked off by hand. As soon as possible after picking, they are conveyed to the oast houses, where they are spread upon hair cloths and thoroughly dried by means of hot air, and afterwards pressed into large hempen bags called pockets, in which they are brought to market.

The hop crop is a very fluctuating one. In 1859 it amounted to 68,496,727 lbs., but in 1860 it was only 11,162,777 lbs.; whilst the imports of foreign hops in the same years were respectively 248,640 lbs., and 7,718,816 lbs. The Excise duty of 1½d. per lb., and the Customs duty of 2½s. per cwt. (now reduced to 1s.), yielded in 1860 a total revenue of 79,439l.

Hops serve three important purposes in brewing; 1st, they impart an agreeable flavour to the beer; 2nd, they check acetous fermentation and thus render the beer capable of being kept; 3rd, their tannin helps to clarify the beer by precipitating the albumen of the barley. Their active qualities reside principally in the golden yellow grains of *lupuline* with which they are covered. Besides their use in brewing they are sometimes prescribed as a tonic; and, on account of their narcotic odour, pillows stuffed with them are employed to induce sleep. [A. S.]

#### HUNGERWEED. *Ranunculus arvensis*.

HUNNEMANNIA. An erect-growing perennial belonging to the *Papaveraceae*, and allied to *Echscholtzia*, from which it is distinguished by its single peltate four-ribbed stigma, by its ten-ribbed pod-like seed-vessel, and by the absence of a disk-like receptacle. *H. flemingii*, the only species, is a native of Mexico; it grows to the height of two or three feet, with glaucous leaves resembling those of the fumitories, and bears large solitary terminal flowers like those of *Echscholtzia*. [O. A. J.]

HUNTERIA. A genus of dogbanes, having a funnel-shaped corolla with a border of five oblique divisions; five stamens attached to the upper part of the tube of the corolla; and a fruit consisting of twin berries with two seeds. The species are natives of Asia, and attain considerable size; the leaves are in pairs or threes, entire and smooth; and the flowers are small in terminal or axillary clusters. [G. D.]

HUNTLEYA. A small genus of epiphytal orchids of tropical America, related to *Zygopetalum*, from which, according to Dr. Lindley, there is nothing to distinguish them except the excessively enlarged column, and the union of the sepals at the base as in *Macillaria*. *H. violacea*, from Demerara, has large flowers, of an intense violet colour, which is not at all usual amongst orchids. The plant consists of a short stem with a few wiry roots, a tuft of strap-shaped leaves, and one-flowered drooping stalks from the axils of the lower leaves. The sepals and petals are oblong and crisped, the lip kidney-shaped, with a naked brown grooved crest, and the column boat-shaped as large as the lip. *Bollea violacea* is another name for it. *H. Melegria* is of somewhat similar habit, but with an erect flower-stalk, pointed sepals and petals of a pale yellow at the base and claret-coloured towards the apex, and a nearly white lip. This plant is called *Batemannia Melegria* by Reichenbach. [A. A. B.]

#### HUNTSMAN'S CUP. *Sarracenia purpurea*.

HURA. A genus of the spurge-wort family, differing from all others in the many-celled ovary, and the peculiar structure of the sterile flowers. *H. crepitans*, the Sand-box tree, indigenous in tropical America, known as Javilla in Panama, Acupa and Habillo in New Granada, and commonly cultivated in most tropical countries, is the only species. It is a branching tree of thirty to forty feet high, often planted for the sake of its shade, for which it is well adapted, having a great abundance of glossy poplar-like leaves. The reddish inconspicuous flowers are sterile, and fertile on different plants; the former in stalked catkin-like heads, each flower with a cup-shaped calyx, and a central column around which are one or many rows of scale-like bodies, each supporting on its concave face a stamen; the latter, solitary and stalked in the axils of the leaves, with a like calyx and a rounded ovary terminated by a singularly long trumpet-shaped style, the terminal cup-like portion of which a reflexed many-toothed border. The curious, rounded, hard-shelled fruits are about the size of an orange, and have as many deep furrows as there are cells, each cell containing a single flattened seed. When the fruit is ripe and exposed to the action of a dry atmosphere, it bursts with great force, accompanied by a loud sharp crack like the report of a pistol, for which reason it is often called the Monkey's Dinner-bell. The seeds are emetic, in 1

green state violently purgative, but when dry, according to Lunan, they lose this

*Hura crepitans.*

property. An oil is extracted from them and sometimes used as a purgative, about twenty drops of it being equal in action to a table-spoonful of castor-oil, and less nauseous. A venomous milky juice is abundant in all parts of the plant, and if it be applied to the eye causes almost immediate blindness. The wood is extremely brittle, and the hollowed trunks are said to be used in the West Indies as vats for containing cane juice. [A. A. B.]

**HURDA, HURRAH, or HURITUKEE.** Indian names for the *Myrobalaus*, *Terminalia Chebula*, and *citrina*.

**HUREEK.** An Indian name for *Paspalum scrobiculatum*.

**HURRBURR.** *Arctium Lappa*.

**HURRYALEE.** *Cynodon Dactylon*.

**HURSINGHOR.** An Indian name for the flowers of *Nyctanthus arbor-tristis*.

**HURSTBEECH.** *Carpinus Betulus*.

**HURTLEBERRY.** *Vaccinium Myrtillus*.

**HURTSICKLE.** *Centaurea Cyanus*.

**HUSSEIA.** A curious genus of puff-balls, named after the late Mrs. Hussey, distinguished by a cylindrical stem, supporting a globose peridium with a plicate terminal mouth, clothed with a gelatinous veil, which ultimately is turned back from the pileus and top of the stem. The only species grows on the naked soil, and has hitherto been found nowhere except in Ceylon. [M. J. B.]

**HUTCHINSIA.** A genus of *Cruciferae*, allied to *Lepidium*, but differing in having two seeds in each cell of the pouch, which is elliptical, with compound keeled valves without any ring or notch at the summit. They are small annuals with pinnately parted leaves, and small white flowers. One species, *H. petraea*, occurs in the western part of England. [J. T. S.]

**HUTTIA conspicua**, a small rush-like plant with numerous branches, but without leaves, or with the leaves reduced to very minute scales, is the only species of this genus of *Dilleniaceae*; a native of the sandy plains lying between the Hutt and

Murchison rivers on the western coast of Australia. The flowers have five egg-shaped sepals, five roundish petals with their bases contracted into short claws, and stamens arranged in two series with their bases united, the inner consisting of two broad ones, and the outer of ten, seven only of which bear anthers. They have two single-celled free ovaries crowned by thread-like styles. [A. B.]

**HYACINTH.** *Hyacinthus*. — of Peru. *Scilla peruviana*. —, CAPE. *Scilla corymbosa*, and *brachyphylla*. —, FETTERED. *Muscari comosum monstrosum*. —, GRAPE. *Muscari*. —, LILY. *Scilla Lilio-Hyacinthus*. —, MISSOURI. *Hesperocordium*. —, SPANISH. *Hyacinthus amethystinus*. —, STARCH. *Muscari racemosum*. —, TASSEL. *Muscari comosum*. —, WILD. *Hyacinthus non scriptus*. —, of America. *Cumassia esculenta*. —, STAR. *Scilla amara*.

**HYACINTHORCHIS variabilis.** The name of a pretty terrestrial Japanese orchid, having one or two lance-shaped ribbed radical leaves a foot in length, and a flower scape exceeding the leaves and bearing a number of narrow-petaled pink blossoms, each about an inch long. This seems almost identical with the *Crematista Wallichiana* of the Himalaya. [A. A.]

**HYACINTHUS.** A well-known genus of very handsome liliaceous bulbs, of which large numbers of garden varieties are grown in Holland for exportation. The original of the common *Hyacinth*, *H. orientalis*, is a native of the East about Aleppo, Bagdad, &c., and is a stout bulb with fleshy linear oblong leaves, and a loose spike of drooping flowers, of which the perianth is bell-shaped with a six-parted regular limb of oblong nearly equal recurved segments, and encloses six equal stamens, and a subglobose three-celled ovary, crowned by a short erect style, and a three-cornered obtuse stigma. From this the various coloured, full-spiked single and double varieties of the garden *Hyacinth* have been produced. A smaller flowered species, *H. amethystinus*, found in the south of Europe, has the flowers of a bright blue, and is exceedingly pretty. [T. M.]

**HYÆNA POISON.** *Hyenanthe capensis*.

**HYÆNANCHE.** A genus of *Euphorbiaceae*, containing only one species, *H. capensis*, a native of the Cape of Good Hope, where it is called Wolveboon by the Dutch and *Hyæna-poison* by the English. It is a tree-like shrub, with smooth, leathery leaves arranged in whorls, and the small flowers of separate sexes on the same plant. This shrub has acquired the name of *Hyæna-poison* bush from its fruits, which are exceedingly poisonous, being used to destroy those animals, the powder being sprinkled upon raw flesh, which is left in places frequented by them. Dr. Pappe supposes it to contain *strychnine*. [A. S.]

**HYA HYA.** *Tubernaemontana utina*, one

of the innocuous milky plants called Cow trees in South America.

**HYALINE.** Transparent, or nearly so.

**HYALIS.** A genus belonging to the *Mutisia* group of the composite family, differing from its allies in the smooth style, the nature of the pappus, and the ten-ribbed achenes. *H. argentea*, the only species, is found on the salt plains of North Patagonia, where, according to Tweedie, it grows in patches to the extent of acres, and to the exclusion of almost everything else. It is a perennial stiff-branched plant, covered with short white hairs, the stems clothed with grassy leaves, and terminating in corymbs of small white flower-heads. The pappus hairs are white, rough, and in three series. [A. A. B.]

**HYALISMA.** A small slender leafless annual, a native of Ceylon, forming a genus of the curious little order or tribe *Triuridaceæ*.

**HYALOLEPIS.** The generic name of a pigmy annual found in South and West Australia, and belonging to the cudweed group of the composite family. It has very short stems, with grassy leaves surrounding a sessile cluster of small white flower-heads, each head containing a single floret, and the whole surrounded by a common involucre of very thin scales so as to form a compound head. The generic name has reference to the hyaline scales, and the specific *rhizocephala* to the heads which arise from the collar of the plant in close proximity to the root. [A. A. B.]

**HYALOSTEMMA.** The name of an Indian shrub of the anonaceous family, now referred to the genus *Mitras* by Drs. Hooker and Thomson. [M. T. M.]

**HYAWABALLI.** The Zebra wood of Guiana.

**HYBERNACULUM.** The same as Hibernaculum.

**HYBERNAL.** Of or belonging to winter.

**HYBRIDS, HYBRIDÆ.** Plants obtained by applying the pollen of one species to the stigma of another.

**HYDNEI.** A natural order of hymenomycetous *Fungi*, distinguished by the hymenium being broken up into flat teeth, or variously fashioned into spines, tubercles, granules, &c. *Hypez*, which has flat teeth, is sometimes with difficulty distinguished from certain states of *Polygones*, but in the more genuine members of the order which on the other side is confluent with *Articularium*, the peculiar characters are at once evident. *Hydnum gelatinosum* has the substance and nearly the structure of *Tremella*, and is now named by Mr. Currey *Hydnoglaum*. The species are mostly inhabitants of the northern hemisphere, though a few have been found in Australia and the southern regions. [M. J. B.]

**HYDNOCARPUS.** One of the four genera belonging to the poisonous order *Pan-*

*glaceæ*. It consists of six species, all of which are trees, sometimes attaining a large size, and natives of India. The leaves are alternate, oblong lance-shaped, generally somewhat unequal-sided; and the flowers are of separate sexes borne on distinct trees: in both having five sepals and five petals, with an equal number of scales opposite them. The fruit is one-celled, with a hard corky rind, and contains numerous irregularly angled seeds, with thick roughish shells, lying in pulp.

*H. venenata* (or *H. inebrians*, as it is sometimes called) is a large tree, native of Ceylon (where it is called Makooloo) and of the Malabar coast of India. Its fruit, which is about the size of an apple and covered with a brown velvety down, is very poisonous, and is used by the Singalese for intoxicating fish, but the fish taken thus are not fit for human food. The seeds contain a quantity of fatty oil, which is expressed and used by the native Indian doctors as a cure for leprosy and other cutaneous complaints, for which purpose it is greatly esteemed. [A. B.]

**HYDNOPHYTUM.** A genus of cinchonaceous shrubs, inhabiting the Molucca Islands. They are described as being of parasitic habit and frequently dilated at the base, so as to form a cavity, made use of by ants as a nest. The flowers have an inferior calyx with an undivided margin, a four-lobed corolla, with a short tube, into the throat of which the stamens are inserted. The fruit is fleshy with two one-seeded stones. [M. T. M.]

**HYDNORA.** A genus of curious fungus-like leafless plants of the order *Cyttinaceæ*, found in South Africa, parasitical on the roots of succulent euphorbias and other plants. *H. africana*, called Jackal's kost, is said to smell like decaying roast-beef or some fungus, and to be eaten, when roasted, by the African savages. The plant consists of a large succulent hermaphrodite solitary, tubulose, trifid flower, borne on a creeping rhizome; and this flower is succeeded by a globose, baccate, many-seeded fruit. The plant may be compared with *Geaster*, or some such half-buried fungus. [T. M.]

**HYDNUM.** A genus of hymenomycetous *Fungi*, varying greatly in substance, but distinguished by the hymenium consisting of prickles projecting from the pileus. These differ very much in length. Occasionally they are variously cleft or lacinate. Many of the species are of a large size, and supported by a central stem, or much branched with the divisions connate, so as to make a kind of coarse network. *H. repandum*, which is common in woods, where it sometimes occurs in scattered patches, and sometimes in large rings, affords an excellent article of food if carefully dressed, and is scarcely exceeded in delicacy by any fungus. The specimens must be quite fresh and free from insects, and after being sliced into hot water, and gently pressed, should either be care-

fully stewed or rubbed down into a purée. Other species are occasionally eaten abroad. *H. auriscalpium* is one of our most elegant *Fungi*, not uncommon on fir cones. The spongy and corky species are only slightly represented in Great Britain, but of the resupinate forms we have many good examples. *H. aurantiacum* and one or two more have been lately added to our Flora. [M. J. B.]

**HYDRANGEACEÆ** (*Hydrangeads*, *Bou-eraceæ*.) A natural order of Calycifloral Dicotyledons, included in Lindley's Saxifragal alliance of perigynous Exogens, and referred by Bentham and Hooker to *Saxifragaceæ*. Shrubs with opposite simple exstipulate leaves. Flowers in cymes, the central ones complete, the outer ones with large sepals and often barren; calyx adherent, four to six-toothed; petals four to six, deciduous; stamens eight to twelve in two rows, or numerous; ovary of two to five carpels united; ovules numerous, anatropal; styles two to five with kidney-shaped stigmas. Fruit a capsule crowned by the persistent styles, two to five-celled; seeds albuminous, minute. Natives of the temperate part of Asia and America. About one half are found in China and Japan. Some species of *Hydrangea* are used for tea. There are ten genera and nearly fifty species. [J. H. B.]

**HYDRANGÆA.** Showy shrubs, referred by some to the *Saxifragaceæ*, by others to *Hydrangeaceæ*. The distinctive characters are: calyx superior five-toothed; petals five; stamens five; pistils two; capsule two-beaked, two-celled, opening by a hole between the beaks. The best known species is *H. hortensis*, introduced from China by Sir Joseph Banks in 1790. It is distinguished by its broad, smooth, strongly veined leaves, which are toothed, and taper to a point, and yet more strongly marked by its almost globular clusters of large flowers, the colour of which varies in the same plant, from white to blue or pink, according to the soil in which it is grown. The part of the flower which appears to be the corolla, is not so in reality, but a monstrous expansion of the calyx leaves, the rest of the flower being generally abortive. The similarity between the balls of flowers of this plant and those of the guelder rose is obvious; and it is worthy of remark that the resemblance is owing to precisely the same irregularity in each—an undue development of the floral envelope to the detriment of the essential parts of the flower—stamens and pistils. These organs are found only in a few flowers, which of course are the only ones that can produce seeds. [O. A. J.]

**HYDRANGELLE.** (Fr.) *Hydrangea*.

**HYDRANTHELIUM.** A genus of *Scrophulariaceæ*, consisting of small aquatic annuals, with the habit of *Callitriche* or of *Elatine*. The leaves are opposite and cuneate or obovate, the flowers very minute and axillary, with a three-cleft corolla, and three stamens. There are two species, natives of the mountainous districts of

tropical America, one of which has also been found in tropical Africa.

**HYDRASTIS canadensis** is the only species of a genus of *Ranunculaceæ*, found in damp places in woods, in the Northern United States and Canada, where it is called Yellow Puccoon, Orange root, or Canadian Yellow root. It is an herbaceous perennial, with a thick knotty yellow underground stem, or root as it is more frequently called, which in early spring sends up a simple stem, about a foot high, bearing near the top two (or rarely three) rounded hand-shaped leaves, the upper leaf growing close upon the stem, while the lower one has a longish stalk. At the top of the stem is a solitary small greenish-white inconspicuous flower, entirely destitute of petals; the three-leaved calyx quickly falls away, leaving only the stamens and pistils. The fruit is about the size of and greatly resembles a raspberry in its appearance, having juicy flesh of a bright crimson colour. The yellow root of this plant was formerly employed by the American aborigines for dyeing a bright yellow colour, and it is occasionally employed for the same purpose at the present day. It has a strong narcotic odour, with a bitter pungent taste, and possesses tonic properties, on which account it is sometimes used medicinally; it was at one time supposed to be a remedy for cancer. [A. S.]

**HYDRILLA.** A genus of *Hydrocharidaceæ*, allied to *Anacharis*. A slender-stemmed aquatic herb, with whorled sessile leaves, growing in the rivers of India, China, and America. The spathes are axillary and single-flowered, with a six-cleft reflexed perianth, and three stamens which become detached and float on the surface. The female, with a spreading perianth, has a long thread-like tube adhering to the ovary, permitting the stigmas to reach the top of the water. [J. T. S.]

**HYDROCERA.** A genus of *Balsaminaceæ*, consisting of aquatic Indian herbs, with alternate linear or lanceolate glaucous leaves, and solitary axillary two or three-flowered peduncles, the pedicels longer than the common peduncle. They have a calyx of five coloured unequal sepals, the two lateral smaller, and the lowest larger and gibbous at the base, unequal petals, and five stamens, with the filaments united at the apex. The fruit is a drupe, with a five-celled hard interior, each cell containing one seed. [J. T. S.]

**HYDROCHARIDACEÆ.** (*Vallisneriaceæ*, *Anacharideæ*, *Hydrocharads*, *Frogbits*.) A natural order of epigynous monocotyledons belonging to Lindley's hydral alliance of Endogens. Aquatic plants with flowers in spathes, often incomplete; perianth of six leaves, the three inner petaloid; ovary one-celled, or spuriously three to nine-celled; stigmas three to nine; placentas parietal. Fruit dry or fleshy, and opening; seeds albuminous; embryo straight, orthotropal. Natives chiefly of Europe, Asia, and North America,

and growing generally in fresh water. Movements of granules may be seen in the cells of many of the plants. *Vallisneria spiralis* is found in the south of Europe. Two species of this genus occur in New Holland. The leaves of *Hydrocharis morsus ranae* are mucilaginous and astringent. *Anacharis Aleinastrum* has become naturalised in many parts of Britain. There are nineteen genera, and about thirty-six species. Examples: *Udora*, *Vallisneria*, *Stratiotes*, *Hydrocharis*. [J. H. B.]

**HYDROCHARIS.** A small floating aquatic, giving name to the order *Hydrocharidaceae*, and distinguished by the following characters: ovary six-celled; stigmas six, wedge-shaped, two-cleft; stamens six to nine. *H. morsus ranae*, or Frogbit, is an elegant little plant, inhabiting ditches, ponds, and the still back waters of rivers. It increases by floating horizontal runners which shoot out to a considerable length; from the joints descend tufts of long, scarcely branched roots, which penetrate deep into the mud. From the same points issue pendulous leaf-buds, supported on long footstalks; each of these buds is composed of two leaf-like scales, folded together and curiously enveloping the embryo leaves of the future plant. The leaves are stalked, kidney-shaped, entire; the flowers of three delicate white petals, rise several in succession, from a pellucid membranous sheath, and bear the stamens and pistils on separate plants. This is one of the most desirable plants for the freshwater aquarium. French, *Morene*; German, *Froschbiss*. [C. A. J.]

**HYDROCHLOA.** A genus of grasses belonging to the *Oryzæ*. *H. carolinensis*, with *Zizania aquatica*, the Canada rice, constitute the genus *Hydrophyrum*. The name is also given to another group of grasses synonymous with *Glyceria*. [D. M.]

**HYDROCLEIS.** A genus of aquatic plants, belonging to the *Rutonaceæ*, growing in tropical America. They have the leaves all radical, cordate ovate. The flowers are on simple scapes, large, yellow, with the three inner perianth segments petaloid and deciduous; the three outer green and persistent; they have numerous stamens, and from six to nine carpels. *Limnocharis*, as now restricted to *L. Plumieri*, differs in having fifteen to twenty carpels, and an umbel of flowers. [J. T. S.]

**HYDROCOTYLE.** An extensive genus of umbelliferous plants, mostly herbaceous and of humble growth, but some approaching shrubs in habit, difficult of discrimination, and possessing little interest except for the scientific botanist. The only native species, *H. vulgaris*, common Pennywort, is one of the few British plants which have peltate leaves. The plant bears an ill name from being considered, in conjunction with two or three other bog plants, the fruitful cause of rot in sheep, an unfounded accusation, for it possesses no noxious properties, and sheep more-

over refuse to eat it. German, *Wasser-nabel*. [C. A. J.]

**HYDRODICTYÆÆ, HYDRODICTYON.** An order and genus of green-spored *Algae*, remarkable at once for beauty and singularity of structure. The plant, when full-grown, resembles a long purse, consisting of a beautiful regular network of threads. These threads contain a mass of endochrome which is ultimately resolved into minute zoospores; these arrange themselves, within the articulation which gave them birth, into polygons, in such a way as, when united, to form a network, which gradually increases till it resembles the parent plant; each joint, therefore, of the network gives rise to a new individual. This singular mode of development is without example in other orders. The other genera usually ascribed to this order are probably related to *Anadyomene*. *Hydrodictyon utriculatum* is found in fresh water, though rarely, in several parts of Europe, and has long been known as growing every year in the pond in the Old Botanic Gardens at Cambridge. It has also been found in the United States. [M. J. B.]

**HYDROGLOSSUM.** A genus of climbing ferns of the *Schizæa* group, the exact analogues of *Lygodium* in habit and fructification, but differing therefrom in having netted instead of free veins, the venules anastomosing in from two to four series of unequal obliquely-elongated hexagonal areoles. The species are but few, and are found in the Pacific Isles, Madagascar, and Mexico. [T. M.]

**HYDROLEACEÆ.** A name given by Brown to the plants now included in the order *Hydrophyllaceæ*. [J. H. B.]

**HYDROLEA.** A genus of *Hydrophyllaceæ*, containing several species common in America, and rare in Asia and Africa. They are marsh plants, often armed with axillary spines, and bearing alternate entire leaves, and axillary or terminal blue flowers, which have a calyx of five persistent sepals, a rotate campanulate corolla, five stamens inserted in the tube of the corolla, and a two-celled ovary with many anatropal ovules, attached to fungous placentæ. The capsule is two-celled with numerous small striated seeds. The leaves of *H. zeylanica* are bitter; in India they are beaten into pulp, and applied as a poultice to ill-conditioned sores with a beneficial effect. [W. C.]

**HYDROGERA VASA.** The spiral threads inside a spiral vessel; formerly supposed to be tubes conveying fluid.

**HYDROPELTIS.** A genus deriving its name of Water-buckler from the shape of the leaves. It is included among the *Cabombacæ*, and differs from *Cabomba* in the numerous thread-like stamens, and the equally numerous whorled, somewhat fleshy carpels. *H. purpurea*, called also *Brasenia peltata*, is a curious little water plant, with floating peltate oval leaves, and purple flowers, on the end of some-

what thickened flower-stalks. The submerged portions are covered with a mucilaginous substance, formed by the rapid formation and rupture of the cells on the outer surface of the plant. The wide distribution of this plant is hardly less remarkable than its structure, for it has been found in the United States, Canada, Australia, and the Himalaya mountains. In America it is esteemed nutritious, possibly from the large-grained starch it contains. The leaves are somewhat astringent, and have been employed in phthisis and dysentery. [M. T. M.]

**HYDROPHYLLAX.** A genus of *Cinchonaceae*, represented by a creeping herb, native of the sandy sea-shores of India. The corolla, like the leaves, is somewhat fleshy, bell-shaped, with a hairy throat into which the four stamens are inserted. Fruit succulent, four-cornered, with a single seed in each of its two compartments. *H. maritima* is used for dyeing purposes. [M. T. M.]

**HYDROPHYLLACEÆ.** (*Hydroleaceæ*.) A natural order of corollifloral dicotyledons belonging to Lindley's cortical alliance of perigynous Euxogens. Herbs or small trees, usually with alternate and lobed hispid leaves. Calyx five-cleft, persistent; corolla regular, somewhat bell-shaped; stamens five, alternating with the corolla lobes; ovary superior with two parietal placentas; styles two. Fruit a two-valved one-celled or spuriously two-celled capsule, filled with a large placenta; seeds reticulated; embryo small, in hard albumen. Natives chiefly of the temperate and cold portions of America. A few are found in the East Indies, and some at the Cape of Good Hope; some are cultivated on account of their showy flowers. *Hydrolea* has bitter qualities. There are eighteen known genera, and about eighty species. Examples: *Hydrophyllum*, *Nemophila*, *Eutoca*, *Phacelia*, *Hydrolea*, *Whitlavia*. [J. H. B.]

**HYDROPHYLLUM.** A genus of American herbaceous perennials, giving name to the order *Hydrophyllaceæ*. The corolla is five-cleft and furnished with as many corolline scales, which are attached by the back, but free at the margins and point; the stamens exceed in length the tube of the corolla, and the stigma is two-cleft. The flowers of these plants resemble those of the borage tribe, not only in the structure of the corolla, but in their curled arrangement while in bud; but the seeds are enclosed in a single one-celled or half-two-celled capsule, and the leaves are always more or less divided. The species grow among moist shady rocks, and derive their name (which means Water-leaf) from their having in the spring a small quantity of water in the cavity of each leaf. In North America the leaves of *H. virginicum* are eaten under the name of Shawanese salad. French, *Hydrophyllé*; German, *Wasserblatt*. [C. A. J.]

**HYDROPIPER.** *Polygonum Hydro-piper*; also *Elatine Hydro-piper*.

**HYDROPYRUM.** A genus of aquatic grasses, distinguished by the spikelets being monœcious, the male and female flowers in the same panicle. Male flowers without glumes; pales two, membranous, the lower acute and mucronate, five-nerved, concave, the upper three-nerved; stamens six. Females with rudiments of glumes; pales two, membranous, the lower three-nerved, ending in a long awn; styles two, short and spreading. *H. esculentum*, the Canada Rice, is a well-known plant of North America, where the large seeds yield a considerable amount of food to the wandering tribes of Indians, and feed immense flocks of wild swans, and other aquatic birds. It grows well in Britain when it is once established, but it is liable to die away if not cared for. [D. M.]

**HYDROSTACHYS.** Aquatic herbs, natives of Madagascar, constituting a genus of *Podostemaceæ*. They are of little general interest, but are known by their unisexual naked flowers, and by their fruit, which consists of two carpels, forming a single cavity, and bursting by two pieces or valves. [M. T. M.]

**HYDROTÆNIA.** A genus of bulbous *Tridaceæ* allied very closely to *Steyrrochium*, from which it differs in having the anthers opposite the sepaline divisions; it has, moreover, quite a different habit, imitating rather the lilaceous genus *Fritillaria*. The perianth is bell-shaped with the parts almost isomericous, the petaline divisions clawed, and marked above the claw with a triangular zone which glitters as if constructed of rock crystal; there are three monadelphous stamens, and a trifid style whose branches divide into three erect stigmas of a remarkable character, each parting into two arms which are rolled up as if to form a gutter, and bear a dense mass of bright papilla at the end, and a single tooth on the inner edge, while between the arms stands a short mucro free from glands, and forming a minute horn. The name refers to the glittering dewy or watery band on the petaline segments. *H. Meleagris*, the only species, is a native of Mexico, and has a single plicated ensiform leaf, and fusaceous campanulate purple flowers, pendulous on slender footstalks. [T. M.]

**HYEMAL.** Of or belonging to winter. Usually applied to plants that bloom in winter.

**HYGROPHILA.** A genus of *Acanthaceæ*, containing about two dozen species, which are widely distributed over the tropical and sub-tropical regions of the world. They are erect or decumbent herbs, growing in moist localities. The flowers are in sessile axillary clusters, and have a calyx of five or rarely four sepals; a two-lipped corolla, with the upper lip notched, and the lower three-lobed, the lobes contorted in the bud; and four didynamous stamens. The oblong or linear capsule has seeds along its whole length. [W. C.]

**HYGROPHORUS.** A genus of *Fungi*,

separated from *Agaricus* on account of their peculiar habit, their waxy not membranaceous gills, and granular intermediate substance. Though the characters seem rather indefinite, there is no difficulty in recognizing the genus at the first glance. Many of the species are extremely beautiful and exhibit the most brilliant colours, but these are often not characteristic, the same species presenting frequently very different hues. A great many of them grow in open pastures, and abound in the fields in autumn, the woodland species generally exhibiting a different type. All of them readily imbibe and part with their moisture, and several are covered all over with a glutinous coat. Few, if any, are admitted into our kitchens, though no doubt some are wholesome. *H. conicus*, one of the commonest, exhibits every shade between yellow and scarlet, and may always be known by its turning black when bruised. *H. psittacinus* presents various tints even in the same specimen, its colours vying with those of parrots. The genus is little known out of Europe and the United States; Ceylon has, however, afforded some beautiful species in this as in other genera of *Agaricus*, in which the island is peculiarly rich. [M. J. B.]

**HYGRORYZA.** A genus of Grasses belonging to the tribe *Oryzæ*, distinguished by the spikelets being hermaphrodite, one-flowered; glumes two, the lower terminating in a tail-like bristle, the upper acute; pales slender, toothed at the apex; stamens three; styles one. *H. aristata* is a native of the West Indies. [D. M.]

**HYGROSCOPICITY.** The property of extending or shrinking upon the application or removal of water.

**HYLAS.** *Myriophyllum*.

**HYMEN.** In Greek compounds = a membrane, or membranous.

**HYMENACHNE.** A small group of South American grasses, proposed as a separate genus by Nees ab Esenbeck, but now referred to *Panicum*. They are represented by the *P. Myurus* of Lamarck, and consist of some three or four species in which the panicle of flowers is simply branched, and the spikelets are disposed either in a spike or racemose manner. [T. M.]

**HYMENANTHE.** A synonym of *Viscaria*, one of the subdivisions of *Lychnis*.

**HYMENÆA.** A genus of leguminous plants of the section *Cæsalpinia*, so named from Hymen, the god of marriage, in consequence of the leaves being composed of a pair of leaflets. Its flowers have a woody tubular calyx with two bracts at its base, and divided into five deciduous segments, the two lower of which are sometimes joined together; and five unequal petals, inserted along with the ten distinct stamens into the summit of the calyx tube. The fruit is a pod with a hard woody shell containing several seeds imbedded in a fibrous pulpy substance, which eventually becomes dry and mealy, and is commonly eaten by Indians.

*H. Courbaril*, the common West Indian

Locust tree, called Algarroba in Panama, Jatai in Brazil, and Simiri in Guiana, is a common tree in most parts of tropical South America. It grows to an enormous size, and, according to some calculations, lives to a very great age, some of the trees at present existing in the forests of Brazil being supposed to have been of considerable size at the commencement of the Christian era. Most of these old trees are supported at the base by immense buttresses, and at this part some have been measured no less than eighty-four feet in circumference, while even at the top of

*Hymenae Courbaril*.

the buttresses, where the trunk assumes the usual cylindrical form, the circumference is as much as sixty feet. The timber is of a fine brown colour, hard and close-grained; it is used for building and other purposes in South America, and is occasionally exported to this country. It is covered with a very thick but light bark, which is used by the Indians for making canoes. A valuable resin, resembling the anime of Africa, exudes from the trunk, and large lumps of it are found about the roots of old trees. [A. S.]

**HYMENANDRA.** A genus of *Myrsinaceæ*, consisting of a single species found in the Silhet district of India, and differing from the other genera in the anthers being united to each other by their margins, and in the ovaries containing numerous ovules. *H. Wallichii* is a stout evergreen shrub often cultivated in plant stoves for the sake of its handsome leathery and glossy leaves, which are shortly stalked, and in form and size a good deal like the leaflet of a horse-chestnut. The pretty pink flowers are disposed in compound lateral umbels have wheel-shaped five-parted corollas half an inch across. The fruit is a berry about the size of a pea. [A. A. B.]

**HYMENANTHERA.** A genus of Australian shrubs, belonging to the violet family. The leaves have no stipules; the flowers are regular; the five short stamens are alternate with the petals, the anthers being

connected by the long crest which surmounts their lobes. The fruit is succulent, surrounded by the persistent outer whorls of the flower, either one or two-celled. From other genera this differs in its nearly regular flowers, and in its five stamens which are united into a tube, having at their base scale-like appendages prolonged beyond the anthers. [M. T. M.]

**HYMENIDIUM.** A genus of umbellifers, distinguished chiefly by each half of the fruit being provided with five ridges prolonged into wing-like membranes. The genus comprehends herbaceous plants natives of Kashmir, having the leaves much divided, and membranous bracts longer than the flowers. [G. D.]

**HYMENIUM.** The fructifying surface in *Fungi*, more properly applied where the spores are naked, but used also to express the same condition in such genera as *Helvella* and *Peziza*. It is not used where the fructifying cells are contained in a distinct perithecium, the word *nucleus* being then more generally substituted. [M. J. B.]

**HYMENOCALLIS.** A genus of beautiful paniculiform *Amaryllidaceae*, consisting of bulbous plants, with usually persistent lorate leaves and flattened two-angled solid scapes, bearing an umbel of from one to a score of flowers, which are white and very fragrant. The perianth has a straight elongated tube scarcely widened at the throat, a six-parted limb of subequal linear segments, a funnel-shaped or rotate spreading coronet on the edge of which the six stamens are developed, and a long flaccid declinate style with a roundish minutely fimbriated stigma. There are some score or more of species inhabiting the West Indies and South America. [T. M.]

**HYMENOCARDIA.** A genus of the order *Stilaginaceae*, differing from the others in having samaroid (somewhat maple-like) fruits. Of four known species three belong to West Africa, and one to the Malay peninsula. They are deciduous shrubs or small trees, with ovate oblong or elliptical leaves covered with glandular dots underneath, and minute reddish flowers, the sterile and fertile borne on different plants, the former in short axillary spikes, the latter solitary or in racemes. These are succeeded by two-celled two-winged fruits. *Samaropsis* is the name applied to the Malayan species by Miquel. [A. A. B.]

**HYMENOCYSTIS.** *Woodsia fragilis*.

**HYMENODES.** Membranous in texture.

**HYMENODICTYON.** Indian trees closely related to *Cinchona*, distinguished by the projecting style, terminated by a lobed, somewhat club-shaped stigma; and the fruit, which is not surmounted by a limb of the calyx, forming a capsule, bursting by two valves. The seeds are numerous, surrounded by a membranous netted wing, whence the name. *H. excelsum* a native of Ceylon and the peninsula of India, and *H. utile* a native of Malabar, have soft mahogany-coloured

wood. The bark of the first-named is very astringent, as much so as that of the true cinchonas. This bark is used for tanning purposes. [M. T. M.]

**HYMENODIUM.** The principal species of this genus of acrostichoid ferns is a coarse simple-fronded West Indian plant, with large oblong-ovate fronds, sprinkled over rather thickly with long black hairs. The fertile fronds are of the same form, but smaller, and entirely covered with spore-cases on the under surface. The veins are uniformly reticulated in coarse hexagonal or elongated meshes, without free veinlets. Also called *Dictyoglossum*. [T. M.]

**HYMENOGLOSSUM.** A name proposed by Presl for the *Hymenophyllum cruenum* of Chili.

**HYMENOLENA.** A genus of umbellifers, having the fruit ovate or oblong, each half with five nearly equal winged ribs, and two oil-cells in the commissure. The species are smooth perennial herbs, natives of Nepal, having much-divided leaves, and terminal many-rayed umbels, each surrounded by a many-leaved involucre, the pieces of which are membranous, often toothed or cut. [G. D.]

**HYMENOLEPIS.** A small and well-marked genus of polypodiaceous ferns, referable to the tribe *Pleurogrammeae*. The fronds are simple opaque and linear lanceolate or lorate, with the apex very much contracted, usually spike-like and fertile, so much contracted, indeed, that the continuous line of spore-cases which lies on each side the costa is in the early stages covered by the revolute margin, as in the fertile parts of *Lomaria*. The veins are compoundly anastomosing, forming crowded irregular areoles, in which occur variously directed free veinlets. The species are found in India and the islands of the Pacific and Indian Oceans. [T. M.]

**HYMENOMYCETES.** The highest of the six great divisions of *Fungi*, containing those naked-spored genera, in which the fructifying surface or hymenium is at length completely exposed. In a few of the agarics and boleti, there is at first a common wrapper (voile), or a partial veil covering the hymenium, but in far the greater part it is exposed even in infancy. The hymenium literally applies to the fruit-bearing stratum only, the organs on which it is spread being called the hymenophorum, but in general it is applied to the whole apparatus, whether consisting of gills, wrinkles, tubes or pores, spines or tubercles, or if all inequalities in the surface cease and it becomes perfectly even. In the higher species, the hymenium is horizontal and turned away from the light, but in those of an inferior dignity it is often resupinate, though in such cases there is frequently a tendency to attain the usual position by the turning over of the border. In a few rare cases, on the contrary, amongst agarics, where a species was in the first instance stipitate,

the pileus is at length turned over, the stem becoming gradually lateral, while it ceases to increase in length; and in a little species from Borneo, the stem is completely torn off, and remains like a little style in the centre.

The *Hymenomyces* are for the most part either soft and fleshy, or by various transitions hard and compact, but a few species are gelatinous, and some of these when dried up recover their form on the application of moisture. They pass by almost imperceptible degrees into *Hyphomyces*, by means of *Typhula* and *Isaria*; into *Gasteromyces*, by means of *Agaricus* and *Montagnites*; and into *Contomyces* by means of *Tremella* and *Podisma*. The transition into the sporidiferous fungi is not so acutely marked, the relation of *Clavaria* to *Geoglossum* being rather one of analogy than affinity. They are fungi of great importance as containing the greater number of the larger species, and supplying an immense quantity of excellent food, besides answering other domestic ends. In the organised world their use is to decompose more rapidly such structures as have answered their immediate purpose. The largest trees, when once attacked, soon acquire a condition which is favourable to other causes of decay.

The hymenium being the prominent element in those plants affords the readiest mode of their classification. The following natural orders depend, therefore, on its conformation:—

*Agaricini*: those which bear gills or gill-like wrinkles.

*Polyporei*: those with pores or tubes.

*Hyalini*: those with spines or tubercles

*Auricularini*: those destitute of true gills.

*Clavariet*: pileus club-shaped.

*Tremellini*: substance gelatinous.

The *Hymenomyces* occur in all parts of the world, extending southwards as far as Campbell's Island, and northwards to Spitzbergen. They abound, however, most in warm and moist temperate regions, as in Sweden, which is perhaps the richest and most prolific country in the world for these fungi. There are no certain traces of them in any geological formation older than ancient peat mosses. [M. J. B.]

**HYMENOPAPPUS.** A genus of annual or perennial North American herbs of the composite family, with angular stems, pinnately lobed or cut leaves, usually clothed with lax white wool, and white or yellow flower-heads in corymbs at the ends of the branches. From its allies the genus differs in the florets being all tubular and perfect, and in the involucrel scales being white and petal-like at the tips, thus giving the heads a ragged appearance. [A. A. B.]

**HYMENOPHORUM.** The cellular or filamentous structure in hymenomycetous Fungi, on which the hymenium or fructifying surface is spread like wax upon a mould. In the *Agaricini* and *Polyporei*, it is identical with what is called the trama or

inner substance of the gills or partitions of the pores. [M. J. B.]

**HYMENOPHYLLUM.** A genus of film ferns, of which one or two species occur in Britain, and many others are scattered over the hot damp forests of the tropics, both insular and continental, as well as the moist ravines of New Zealand and Chili. The fronds vary greatly in size and character, some being minute and others of considerable size and length, some simple and others decomposed; but all, or nearly all of them, filmy pellucid in substance, and with creeping thread-like rhizomes. The spore-cases are collected around free projecting hooks formed of the ends of the veins which traverse the fronds, and are contained within oblong or suborbicular two-valved marginal cysts. *Hymenophyllum* differs from *Trichomanes*, the other principal genus of film ferns, by the two valves of the involucre being separate, and not blended into a cup. [T. M.]

**HYMENOPHYSA.** A genus of *Cruciferae* closely related to *Lepidium*, and differing chiefly in the little fruits—the size of mustard seed—being globular instead of compressed. There are two species known, *H. fenestrata*, found in Persia, and *H. pubescens*, in the Altai. The latter is a perennial branching, leafy-stemmed herb, whose branches terminate in racemes of numerous small white flowers. [A. A. B.]

**HYMENOPYRAMIS brachiata**, the only species of the genus, is a scandent East Indian shrub of the *Verberna* family, with quadrangular stems, opposite entire ovate leaves, hoary underneath, and terminal leafy panicles of very minute flowers, with tubular corollas, having four-toothed borders. The calyx, at first of four minute teeth, enlarges when the flowers wither, and encloses the small ripe hairy nut, in the form of a four-winged bladder. This character serves to distinguish the genus from its allies. [A. A. B.]

**HYMENOXYS.** A genus belonging to the corymbiferous tribe of compound flowers. The scales of the involucre are in two rows, the inner largest, all rigid and pressed close to the flower; the receptacle is chaffy, and furnished with small glands; and the fruit is downy with chaffy pappus. *H. californica*, an annual species, grows a foot high, with slender branched stems, pinnatifid leaves, and yellow flowers. [C. A. J.]

**HYMENULUM** A disk or shield containing a seed, but without excipulum.

**HYOBANCHE.** A genus of fleshy and woolly plants, parasitical on various roots, found in the flat lands of the Cape of Good Hope. The stem is closely covered with ovate appressed scales. The flowers are in a dense ovate spike, and have an unequally five-cleft calyx, a clavate corolla slightly curved and vaulted, with a very narrow oblique mouth, and obsolete limb, four stamens of nearly equal length, the anthers by abortion one-celled, and a more or less completely two-celled ovary. The capsule

is sub-globose, fleshy, containing numerous minute round seeds. The habit and structure of this genus seem to place it in *Orobanchaceae*, where it would, without doubt, remain, but for its two-celled ovary, and axile placentæ, characteristics of the *Scrophulariaceae*. [W. C.]

**HYOPHORBE.** Palms inhabiting the island of Bourbon and Mauritius, and having tall cylindrical stems marked with circular scars, and a crown of graceful pinnate leaves. The male and female flowers grow on distinct trees, or a few males are occasionally interspersed among the females, the flower-spikes being simply branched and growing out from beneath the leaves, with a single spathe at their base. Both sexes have a three-sided three-lobed bell-shaped calyx, and a three-parted corolla. The fruit has a fibrous fleshy rind, and contains a single seed.

*H. Commersoniana*, frequently called *H. indica*, or *Areca lutescens* in English gardens, a native of Bourbon, has a smooth trunk thirty or forty feet high, and from four to six inches in diameter, almost cylindrical, except at the base where it swells out to nearly double its usual diameter. Its leaflets are about two feet long, and two inches wide, divided at the top into two sharp points. It has a nearly round fruit covered with rough tubercles. *H. amaricaudis*, a native of the Mauritius, much resembles this, but is taller, and its leaflets are narrower, and more densely covered with chaffy scales; its fruit, also, is smooth and olive-shaped. [A. S.]

**HYOSCYAMUS.** This name is the Latinised version of the ancient Greek name for the common Henbane, and literally signifies hog-bean. It is applied to a genus of *Atropaceæ* or *Solanaceæ*, characterised especially by the corolla, which is funnel-shaped, and by the fruit which is enclosed within the persistent calyx, and consists of a capsule which opens by means of a transverse valve, like the lid of a tankard or pix.

The most interesting species of this genus is *H. niger*, the Henbane, an annual or biennial plant, widely distributed throughout Europe and Western Asia, frequently found by roadsides, or in other localities, whither it has most probably been brought by the agency of man, the plant having been long cultivated for its medicinal qualities. In this country the Henbane is found growing spontaneously in the vicinity of old ruins, on rubbish heaps, and not unfrequently by the seashore. The whole plant is densely covered with thickly woven hairs, and by a sticky heavy-smelling exudation. The stem attains a height of one to two feet, and has oblong sessile, irregularly lobed leaves, the upper ones clasping the stem. The flowers are borne on very short stalks in the axils of the leaves, and look all in the same direction; the calyx enlarges as the fruit ripens; the corolla is funnel-shaped, of a dull yellow colour, traversed by a network of purple veins. A variety sometimes oc-

curs in which the corolla is not marked with these veins, but the above-mentioned characteristics are amply sufficient for the determination of the plant. The leaves of this plant are employed in the form of extract, &c., for the purpose of tranquillising and allaying irritability of the nervous system, to alleviate pain and procure sleep. It is chiefly given in cases where circumstances render it undesirable to employ opium. Other species are grown in gardens or in greenhouses, all possessing more or less of the same properties as the common henbane. [M. T. M.]

**HYOSERIS.** A small genus of annual composite weeds, having the habit and foliage of *Taraxacum*. The flower-scape is thickened and club-shaped upwards, and bears a single yellow flower-head. From their near allies they differ in the achenes being of two sorts in each head; the outer corky and cylindrical, the inner with membranous wings, or *vice versa*. The pappus is biserial, and consists of narrow chaffy and unequal scales. The three known species are confined to the Mediterranean region. [A. A. B.]

**HYOSPATHE.** The only species belonging to this genus of palms, *H. elegans*, is a native of the forests in the vicinity of Pará, where it is called *Ublm* by the natives. It is one of the reed-like palms common in the underwood of tropical forests, its stem being about an inch in thickness, marked with rings, and growing five or six feet high. The leaves are from three to four feet long, nearly entire when young, having only a division at the point, but when full-grown they are more or less divided, and become irregularly pinnate. The flower-spikes are produced below the leaves, and bear both male and female flowers. The fruit contains a single seed and resembles an olive in shape, but is of a violet colour. The only part of the plant applied to a useful purpose is the leaves, which are used for thatching, their large size and entire form rendering them peculiarly suitable for that purpose. [A. S.]

**HYPANTHIUM.** The fleshy enlarged hollow of the end of a flower-stalk, such as occurs in the rose, apple, or myrtle. It was formerly regarded as the tube of a calyx.

**HYPECOM.** Small annual herbs of the order *Papaveraceæ*, allied to *Chelidonium*, from which they are distinguished by their four stamens and two stigmas. As in *Chelidonium*, the seed-vessel simulates the pod of a cruciferous plant, and the juice, which is yellow, is said to have the same properties as opium. The root leaves are smooth glaucous and pinnate, and the stem leaves much divided; the flowers are small and yellow. The species occur in sandy places in the south of Europe and some parts of Asia. French, *Cumin cornu*; German, *Lappenblume*. [C. A. J.]

**HYPERBÆNA.** A genus of South American and Mexican plants, belonging to

the *Menthermacoe*, and differing but little from *Cocculus* save by the anthers which are two-lobed, and originally four-celled, and by the styles which are cylindrical and hooked. [M. T. M.]

**HYPERBOREAN.** Inhabiting northern regions.

**HYPERICACEÆ.** (*Eucryphia*, *Tutans*.) A natural order of thalamifloral dicotyledons, belonging to Lindley's guttiferall alliance of hypogynous Exogens. Herbs, shrubs, or trees with a resinous juice, opposite entire exstipulate leaves, usually with transparent dots and blackish glands, and regular flowers. Sepals four to five, persistent, two outer often smaller; petals four to five, unequal-sided, twisted in bud, often bordered with black dots; stamens generally numerous and polyadelphous; carpels three to five, partially united. Fruit a capsule opening at the septa; seeds numerous and exalbuminous. The plants of the order are generally distributed over the world, both in temperate and warm climates. Many species of *Hypericum* yield a yellow juice, and an essential oil. Some of the plants are purgative, others tonic and astringent. Some species of *Vismia* yield a gum resin similar to gamboge. There are 19 genera, and nearly 300 species. Examples: *Hypericum*, *Etoidea*, *Vismia*, *Cratoxylon*. [J. H. B.]

**HYPERICUM.** An extensive genus of herbaceous or shrubby plants giving name to the order *Hypericaceæ*. The sepals and petals are each five in number; stamens collected into three to five bundles; styles three to five; seeds without wings, in a dry capsule. The best known example of the genus is *H. calycinum*, a somewhat shrubby plant one to two feet high, with large almost evergreen leaves, which, like those of most others in the genus, are curiously sprinkled with pellucid dots. The flowers are very large, terminal, solitary. This is commonly planted in shrubberies or extensive rockeries, where it is valued not only on account of its handsome flowers, but because it affords excellent shelter for game. *H. Androsæmum* (by some authors made a distinct genus on account of its berry-like capsules) is in the west of England a common hedge or woodland plant, growing to the height of one and a half feet. The stem is two-edged, the leaves large glaucous, ovate, sessile, with a strong resinous smell; the flowers, which grow in terminal corymbs, are yellow, but less conspicuous than the elliptical capsules, which as they ripen turn red and finally black. The leaves were formerly applied to fresh wounds, which they were supposed to heal; hence the plant was called in French *toute saine*, corrupted into *Tutans*, its common English name. The pellucid dots and black glands in all the species contain an essential oil. *H. pulchrum* is the badge of the McKinnons. French, *Millepertuis*; German, *Johanniskraut*. [C. A. J.]

**HYPERTROPHIA.** An excessive de-

velopment of one part of a plant to the deterioration of others. Where parts of plants possess valuable properties, art steps in to produce an hypertrophy of those parts, as in the turnip, radish, &c. Sometimes the vegetative powers of a plant are so strong as to prevent the formation of flower-buds and fruit. This is called rankness, and is to be suppressed by the withdrawal of nutriment and by root-pruning. Galls produce hypertrophy on every part of plants. The roots of melons are sometimes gouty from the attacks of a minute vibrio. The disease called clubbing, which is a form of hypertrophy, has been already noticed. Some curious transformations of plants, a few of which are encouraged by gardeners, are also referable to the same category. [M. J. B.]

**HYPHA.** The mycelium, or spawn of certain fungals; also the filamentous fleshy watery thallus of certain fungoid plants.

**HYPHÆNE.** A small genus of African palms confined to and widely distributed throughout that continent, more particularly upon the eastern side, extending from Egypt as far south as Natal. The genus is remarkable for having the stem branched, a peculiarity not frequent among palms, each branch terminating in a tuft of large fan-shaped leaves, from amongst which the branching catkin-like spikes of flowers are produced, the different sexes being borne on separate trees. The fruit is about the size of an apple, and has a thick mealy fibrous rind with a smooth polished skin, enclosing a single hollow seed of a horny consistence.

*Hyphæne thebaica.*

*H. thebaica*, the Doom or Doom Palm, or Gingerbread tree of Egypt, grows also in Nubia, Abyssinia and Arabia. It seldom exceeds twenty-five or thirty feet in height, and its stem is frequently three or four times forked or branched in old trees,

HYPHAE NE OR DOUM PALM IN UPPER EGYPT

though when young it is always simple. The fruits, which are produced in long clusters, each containing between one and two hundred, are beautifully polished, of a rich yellowish-brown colour, and of irregular form. In Upper Egypt they form part of the food of the poorer classes of inhabitants, the part eaten being the fibrous mealy husk, which tastes almost exactly like gingerbread, but its dry husky nature renders it unpalatable. The hard tough wood is used for making various domestic utensils; and rosaries are cut out of the horny seed. See Plate 18. [A. S.]

**HYPHASMA.** A name applied to the mycelium of moulds, as subiculum is often given to the same growth in *Sphæria*. In neither case is it absolutely necessary, though, like many other needless terms, consecrated by habit. [M. J. B.]

**HYPHOMYCETES.** One of the great divisions of *Fungi*, containing those species which have naked spores borne on free or only fasciculate threads. In the two first divisions only are the threads at all compacted, and it is by these that they are connected with *Hymenomycetes*. Care must be taken not to confound them with the vesicular moulds which have a similar habit. As they are plants of an extremely simple structure, it is not surprising that some conditions of more compound forms should occasionally exhibit their characters, exactly as the organs of which phanogams are composed have their analogues amongst the simpler cryptogams. Accordingly the early stage of certain species of *Hyporyton* and *Sphæria* cannot be distinguished from them, and the young of *Erysiphe* exhibits all the characters of *Oidium*. A few, moreover, either produce a second subsidiary fruit, as some species of *Aspergillus* or *Peronospora*, but whether they should be removed into the sporidiferous series is at present matter of doubt. A great portion of the moulds which act so prominent a part in the decomposition of organised bodies belong to this section, and some of them, as *Peronospora infestans*, are of immense importance as affecting substances of extensive use to man. As objects of interest for the observer of nature, they exhibit an endless variety of forms, which are frequently most attractive. Most of them, however, require the assistance of the microscope, even for the inspection of their outward form, and they are difficult to observe when moistened on account of their retaining so much air about them. They occur in all parts of the world, and in the shape of yeast some of them perform a most important part in domestic economy. A few have been detected in amber. Like many other fungi they have immense powers of penetration, and accordingly they are found in situations apparently removed from all external access. They occur in the most deep-seated tissues, occasionally producing fruit though removed from the direct influence of light and air, and this not only in the vegetable kingdom. Amongst animals they are the

source of many cutaneous disorders, and sometimes, as in the case of silkworms, they produce death. A case is even mentioned by Mr. Beale, as reported in the *Lancet* of January 1861, in which a few threads seemed to have formed the nucleus of a large calculus. They occur in all climates where there is sufficient moisture, and some of the more common species appear to be complete cosmopolites. The following natural orders have been proposed to include the species:—*Isariacei*: stem compound; spores dry, easily dispersed.

*Stilbacei*: stem compound; spores forming a diffuent gelatinous mass.

*Dematiacei*: fertile threads more or less carbonised; spores often compound.

*Mucedineæ*: fertile threads hyaline or coloured; spores mostly simple.

*Sepedonei*: fertile threads scarcely distinct from the spawn; spores very abundant.

These latter pass evidently into *Contomyces*. [M. J. B.]

**HYPHOSTROMA.** The mycelium or spawn of fungi.

**HYPNÆI.** A natural order of pleurocarpous mosses, with a nodding capsule, elongated footstalk, and mostly cylindrical stems, with imbricated leaves; and distinguished from *Leucodontei* by the cernuous not erect capsules. In a very few species the stem is flat, and the leaves two-ranked. The species for the most part creep over trees, rocks, or shady banks, though sometimes growing in exposed pastures, forming frequently thick tufts. A few are pinate, but are easily distinguished from *Neckera* by their nodding capsules. *Hypnum* is the principal genus; it is now, however, broken up into numerous genera or subgenera. [M. J. B.]

**HYPNUM.** One of the largest genera of mosses which have lateral fruit, numbering above ninety species in Great Britain alone. It has been divided into various genera dependent on slight differences of habit and condition of the leaf-cells, but if capable of accurate discrimination, they are rather to be considered as subgenera. The peristome in all is double, consisting of an outer row of sixteen equidistant lanceolate acuminate teeth, the inner of a membrane divided halfway down into sixteen keeled, often perforated processes, alternating with the outer teeth, with intermediate cilia which are either solitary or two or three together. The capsule is more or less curved or irregular. It differs from *Leskea* in the nodding capsule and the cilia of the inner peristome, and from *Isotrichum* in the curved not straight and symmetrical capsule, and straggling not dendroid habit. Many of the species are very large and ornamental. They occur in all parts of the world. *H. tamariscinum* is much used by the makers of artificial flowers in the construction of moss roses. [M. J. B.]

**HYPO.** In Greek compounds = under.

**HYPOBLASTUS.** The flat dorsal cotyledon of a grass.

**HYPOCALYPTA.** A genus of myrtaceous shrubs, indigenous at the Swan River. The leaves are narrow with a sharp spine at their extremity; and the flowers are rose-coloured, in heads, the tube of the calyx bell-shaped, the petals five with short stalks, and the stamens numerous attached like the petals to the throat of the calyx. [M. T. M.]

**HYPOCALYPTUS.** A South African genus of *Leguminosae*, consisting of a single species, *H. obcordatus*, a handsome bush or small tree with angular stems, trifoliate leaves, having obversely heart-shaped leaflets, and stiff erect racemes of numerous purple pea-flowers terminating the twigs. The standard, which has a white spot at its base, is longer than the keel; and the narrow and smooth many-seeded pod is about two inches long. The two latter characters distinguish it from *Loddigesia* and its other allies. [A. A. B.]

**HYPOCHÆRIS.** A genus of herbaceous plants belonging to the elchoreaceous division of compound flowers. The characters of the genus are: pappus feathery; receptacle with chaffy scales; involucre unequally imbricated; fruit striated, often beaked. *H. radicata*, the long-rooted Cat's-ear, is a very common weed in pastures, rising to about the height of the crop among which it grows; the leaves are runcinate and very rough, and the stems generally bear several large yellow flower-heads, which are sometimes so abundant as to give a tint to the field in which it grows. It is a weed of no interest, rather mischievous than otherwise, from usurping the places of more nutritious fodder. *H. maculata*, a more robust plant found on the magnesian rocks of the Lizard Point, on the limestone of Ormeshead, and a few other places on chalk, generally bears a single very large flower-head. French, *Porcelle*; German, *Saukraut*. [C. A. J.]

**HYPOCHIL, HYPOCHILLUM.** The lower part of the lip of certain orchids.

**HYPOCRATERIFORM.** Having a long slender tube and a flat limb; as in the flower of the primrose.

**HYPOCYRTA.** A genus of *Gesneraceae*, containing a few species, natives of South America. They are procumbent, sometimes erect, under shrubs, throwing out roots from below the origin of the opposite and fleshy leaves. The flowers are axillary, and solitary or several together, with a deeply five-parted calyx, and an urn-shaped corolla gibbous behind at the base, the limb unequally five-lobed or five-toothed; there are four stamens, and the ovary is surrounded by a disk which swells on one side into a gland. The fruit is a one-celled berry. [W. C.]

**HYPODEMATIUM.** *Lastrea*.

**HYPODERMIS.** The inner layer of the spore-case of an urn-moss.

**HYPODERRIS.** A genus of polypodiaceous ferns, allied to *Woodia*, with which

it agrees in having globose involucre sori, and in the involucre being membranaceous, calyciform, and fringed at the edge. It is, however, at once distinguished by its compoundly anastomosing venation. In its aspect, moreover, it is quite dissimilar to *Woodia*, the only species, *H. Brownii*, being a West Indian plant with simple or three-lobed coarse-looking fronds, having much more the appearance of some *Aspidium*. The venal areoles enclose free divaricate sterile veinlets; and the sori are compital, i.e. seated at the points where several veins meet. [T. M.]

**HYPODISCUS.** A genus of *Rastaceae* with both the male and female flowers in spikes. The female flower is solitary with a stalked ovary having an hypogynous or perigynous disk. The species are natives of the Cape of Good Hope. [M. T. M.]

**HYPOESTES.** A considerable genus of *Acanthaceae*, dispersed over Africa, tropical Asia, and Australia, and remarkably abundant in Madagascar. They are shrubs or small trees with entire or dentate leaves, and large purple or rose-coloured flowers in axillary clusters or short spikes, often numerous and forming a terminal leafy thyrse. The flowers are contained in a calyx-like involucre of four more or less united bracts; the calyx is five-lobed; the corolla is two-lipped, with the upper lip entire or notched and the lower three-lobed; there are two stamens with one-celled anthers; and the capsule is compressed and seedless below, but towards the apex enlarged and two-celled, containing four tuberculated seeds. Nearly forty species have been described. [W. C.]

**HYPOGÆI.** A natural order of gastro-mycetous *Fungi*, distinguished by their hymenium resembling the crumb of bread, and by their subterranean habit. Some have a distinct peridium, while others are totally destitute of any covering, and depart from the characters of the tribe to which they belong. They differ from real truffles in the fruit consisting of naked spores. The genera and species are numerous, and confined to temperate regions. Australia and North America produce two or three species. *Melanogaster ambiguus* is used as a substitute for truffles, and is sold in the market at Bath. Several have an extremely offensive smell. These and other fungi of a similar habit have been most exquisitely illustrated in a separate work by the Messrs. Tulasne. [M. J. B.]

**HYPOGÆOUS.** Growing under the earth.

**HYPOGYNOUS.** Growing from below the base of the ovary.

**HYPOLENÆ.** A genus of *Rastaceae*, the species of which are natives of South Australia and of South Africa. The male flowers are like those of *Rastio*; while the females resemble those of *Waldemovia*, but have a sessile fruit, destitute of disk. [M. T. M.]

**HYPOLEPIS.** A genus of polypodiaceous ferns, belonging to the *Cheilanthes*, and not very well distinguished technically from *Cheilanthes* itself, though obviously distinct in habit and aspect, in the large herbaceous fronds and long creeping rhizomes, and also generally distinguishable by the axillary position of the sori in respect to the segments of the fronds. The fronds are twice, thrice, or four times pinnated, with free veins, and punctiform sori at the apex of the veins, covered by reflexed marginal, sometimes herbaceous, indusia. The species are widely dispersed, being found in New Zealand and the Pacific Isles, India, Bourbon, and Mauritius, South Africa, South America, and the West Indies. [T. M.]

**HYPOLYTRUM.** A genus of cyperaceous plants, characteristic of the tribe *Hypolytræ*. It is distinguished by the inflorescence being in fascicled or corymbose roundish panicles, which are many-flowered. Scales imbricated on all sides, none of the lower without flowers; proper scales two, keeled and compressed, the exterior one largest; calyx none; stamens two to three; styles cleft. The majority of the species are natives of Brazil and the West Indies, but some occur in the East Indies. [D. M.]

**HYPOMENOUS.** Free, not adherent; arising from below an organ, without adhering to it.

**HYPOPHYLLIUM.** A small abortive leaf, like a scale, placed below a cluster of leaf-like branches, or leaves.

**HYPOPHYLLOUS.** Growing on the under side of a leaf.

**HYPOPITHYS.** A genus of fir-rapes, distinguished by having the calyx three to five-parted, and the style slender and hollow, ending in a round stigma, bearded at the margin. The species are parasites, on firs and beeches, with leaves in the form of scales, the entire plant pale in colour, and often with an odour of musk. [G. D.]

**HYPOPODIUM.** The stalk of the carpels.

**HYPOPTERIES.** A wing growing from below anything, as the seed of a fir-tree.

**HYPOPTERATE.** Having a wing produced at the base or below.

**HYPOTERYGEL.** An order of pleurocarpous mosses, with three-ranked leaves, the third row being mostly smaller than the others. The accessory leaves remind one of the appendages in *Jungermanniaceæ*. The capsules are mostly lateral, beneath the proper leaves, but sometimes axillary. The genera of this order belong principally to warm temperate regions in either hemisphere. [M. J. B.]

**HYPOSATHRIA.** A condition assumed by the tissues of certain fruits, commonly called bletting. It is a partial decomposition, accompanied by the formation of sugar, and is sometimes promoted artificially

with a view to improve the flavour of harsh fruits, and, indeed, to render them eatable as medlars, services, &c. [M. J. B.]

**HYOSPORANGIUM.** The indusium of ferns, when it grows from below the spore-cases.

**HYPOSTASIS.** The suspensor of an embryo.

**HYPOSTROMA.** The mycelium of certain fungals.

**HYPOTHALLUS.** Delicate filaments which constitute the vegetation of coniomycetous fungals. The inferior stratum of the thallus of lichens.

**HYPOTHECIUM.** The cellular stratum below the thalamium of lichens.

**HYPOXIDACEÆ. (Hypoxis.)** A natural order of epigynous monocotyledons belonging to Lindley's narcissal alliance of Endogens. Herbs with a tuberous or fibrous perennial root, radical linear dry leaves, and trimorous flowers on scapes. Perianth petaloid, adherent to the ovary, six-parted; stamens six, attached to the perianth, the anthers introrse; ovary three-celled; ovules numerous, attached to a central placenta. Fruit dry or berried, one to two or three celled, not opening, with a lateral hilum, and a peculiar beak-like appendage. Natives of the Cape of Good Hope, the East Indies, New Holland, and the tropical parts of America. The roots of some of them are bitter and aromatic, and the tubers of a few are eaten. There are five genera, and upwards of sixty species. Examples: *Hypoxis*, *Curculigo*. [J. H. B.]

**HYPOXIS.** A genus of herbaceous plants, forming the type of the *Hypoxidaceæ*. They are known by their six stamens being inserted into a disk surmounting the ovary, by the style being detached from the corolla, and by the three-celled capsular fruit. These plants are, for the most part, natives of the Cape of Good Hope, and have much of the appearance of some amaryllidaceous plants, but they are not bulbous: several are in cultivation. *H. erecta*, a North American species, is used as an application to ulcers. [M. T. M.]

**HYPOXYLON.** An important genus of sphaeraceous *Fungi*, distinguished by the stroma, in which the perithecia or fruit-bearing cysts are sunk, being free from the wood on which it grows. They are found in all parts of the world. *H. concentricum*, which is common in this country on ash-trees, looking like lumps of cobbler's wax, is a perfect cosmopolite, assuming several forms. The allied *H. verticillatum*, which, though marked like the last with concentric layers within, is loosely cellular, is eaten by the inhabitants of Bhotan. [M. J. B.]

**HYPSEOCHARIS.** A genus referred to *Geraniaceæ*, and found on the Andes at above 10,000 feet elevation. The plant has root leaves resembling those of *Pimpinella Saxifraga*, and axillary peduncles, with

three or four subsessile flowers, fifteen united stamens, and a five-lobed ovary, with several ovules in each cell. [J. T. S.]

**HYPTIS.** A genus of labiates, having the calyx with five nearly equal teeth, which are very acute; and the corolla about as long as the calyx, the upper lip with four entire lobes, the lower undivided. The species are herbs or undershrubs, varying much in general aspect; they are chiefly natives of the warmer parts of South America. [G. D.]

**HYSSOP.** *Hyssopus officinalis*. — of Scripture. *Cupparis spinosa*. —, BASTARD. *Teucrium Pseudo-hyssopus*. —, HEDGE. *Gratiola officinalis*.

**HYSSOPUS.** A genus of Labiate, consisting of small bushy herbs, with lance-shaped leaves, rolled under at the margin, a calyx marked with fifteen ribs, and four fertile diverging stamens. *H. officinalis*, the common Hyssop, of Southern Europe, was once much employed as a carminative in flatulence and hysterical complaints, but is now seldom employed. [M. T. M.]

**HYSTERANTHIOUS.** When leaves appear after flowers; as in the almond.

**HYSTERIA.** *Corymbis*.

**HYSTERIUM.** A genus of pyrenomycetous Fungi, distinguished by a hard more or less linear dark peritheciolum, opening by an elongated narrow aperture. The species grow on naked wood, bark, leaves, &c., and are sometimes so similar to lichens that it is difficult to distinguish them when the crust is worn away or obsolete. *H. Frazini* and *Rosa* are to be found commonly on fallen twigs of ash and rose. The species are numerous, and occur in all parts of the world. [M. J. B.]

**IANTHE.** A genus of *Scrophulariaceæ* closely allied to *Verbascum*, and only differing from the *Blattaria* section of that genus by the stamens, of which two only bear anthers, two being reduced to barren filaments, and there being no rudiment of the fifth. *I. bugulisfolia*, the only known species, grows in the neighbourhood of Constantinople. It has the habit of the more glabrous species of *Verbascum* or *Celsia*, with the leaves chiefly radical, and greenish-yellow flowers, remarkable for their almost metallic appearance when fresh.

**IANTHINE.** Pure blue stained with red, so as to be intermediate between the two colours.

**IBÉRIDE DE PERSE.** (Fr.) *Iberis semperflorens*.

**IBERIDELLA.** A genus of *Cruciferae*, allied to *Hutchinsia*, differing principally in the truncate pouch, with a long slender style. They are small undershrubs, with white or rose-coloured flowers. [J. T. S.]

**IBERIS.** A genus of *Cruciferae*, containing numerous species from Europe, Eastern Asia, and Northern Africa. They are

easily known from most of their allies, by their flat corymbs of flowers with the two exterior petals larger than the others, so that the inflorescence is radiant. These Candytufts are nearly smooth on nals, or small undershrubs, with oblong or linear leaves (pinnatifid in many of the annual kinds), and white pink or purple flowers, fragrant in some of the species. The seed-pouch is oval or roundish, flattened so that the partition is in the narrowest diameter, and the valves compressed, with an expanded wing on the keel. The seed is solitary in each of the two cells, with the radicle bent over the edges of the flat cotyledons, on one side. The most common species is *I. amara*, which is found wild in the south of England as a weed in cultivated grounds, and many of the other species are common in gardens. [J. T. S.]

**ICACINACEÆ.** (*Teacineæ*.) A natural order of thalamifloral dicotyledons, consisting of evergreen trees and shrubs, allied to *Oleaceæ*, and differing from that order in the calyx not enlarging with the fruit; in the stamens being alternate with the petals; in the ovary being normally many-celled, with axile placentation, and one-celled only by abortion; and in the ovules being suspended below the summit of the cell. The plants are chiefly tropical, and there are about thirteen genera and seventy known species. Nothing is known regarding their properties. Bentham makes them a tribe of *Oleaceæ*. Lindley places the order under his herberal alliance of hypogynous Exogens. [J. H. B.]

**ICACINA.** A genus of *Teacineæ*, with shrubby ascending or twining branches, smooth leaves, panicled flowers, and scarlet fruit. Calyx small, five-cleft; petals five, valvate villous; stamens five, alternate with petals, hypogynous; ovary one-celled, with two pendulous ovules. Fruit indehiscent, the seed pendulous with a prominent raphe. There are three or four known species, natives of the western parts of tropical Africa. [J. H. B.]

**ICACO.** *Chrysobalanus Icaco*.

**ICE-PLANT.** *Meembryanthemum crystallinum*.

**JOHNANTHUS.** A genus of grasses, belonging to the tribe *Panicæe*, and now generally included in *Panicum*. The only species described, *I. panicoides*, is a native of Brazil and Guiana. [D. M.]

**ICHNOCARPUS.** A genus of dogbanes, having the stamens five in number, their anthers distinct from the stigma, which is ovate acuminate; and the seed-vessels very slender. The name is indicative of the slender capsules. *I. frutescens* is an ornamental stove shrub, a native of the East Indies, with oval lanceolate leaves, and small flowers. [G. D.]

**ICICA.** A genus of *Amyridaceæ* (*Bursariceæ*), found chiefly in the tropics of the western hemisphere, only two or three of the twenty species occurring in the eastern.

They are mostly large trees, sometimes a hundred feet in height, and nearly all abound in balsamic or resinous juice. Their leaves are either pinnate with a terminal leaflet, or ternate, the leaflets being of a leathery texture, and without the dots usual in some plants of the same order. The flowers are small, usually white or yellowish-green, and borne in racemes or crowded heads at the angles of the leaves; they have a small four or five-toothed calyx, and an equal number of petals, which, along with the eight or ten stamens, are inserted under the cup-shaped fleshy disk. The fruit is a berry containing from one to five hard stones covered with pulp, and containing one seed each.

*I. altissima*, attaining, in the forests of Guiana, a height of one hundred feet, is preferred by the Indians for making their canoes, not only from its large size but on account of its durability and the facility with which it is worked. It is called Cedar-wood in consequence of its fragrant odour, and is used for the inside fittings of houses, for book-cases, &c., its odour preserving books from injury by insects. The balsam obtained from the trunks of many of the species is highly odoriferous, and is commonly used as a perfume in South America. That of *I. heptaphylla*, called Hyawa in Guiana, is used as a remedy against dysentery, and also for coughs. Balsam of Acouchi, yielded by *I. heterophylla*, is employed as a vulnerary. These balsams remain fluid for a considerable time, but ultimately harden, and are then commonly used for burning as incense in churches. So highly charged with resin are the trees, that the branches of one species are used in British Guiana for torches; and the wood of *I. heptaphylla* is called Incense wood. [A. S.]

ICONES. Pictorial representations of plants.

ICOS. In Greek compounds = twenty.

ICOSAËDRAL. Having twenty sides; as the pollen of *Tragopogon*.

ICTERUS. A name given to the yellow condition assumed by wheat and some other plants, under the influence of prolonged wet and cold. More genial weather generally improves the condition of the plants. The disease is, therefore, distinct from chlorosis, which is more frequently constitutional, and, in consequence, past cure. Vine leaves become yellow from their roots being placed under unfavourable circumstances; the remedy, therefore, must be directed to the point from whence the evil is derived. Yellowness is sometimes produced by *Fungi*, and is then irremediable. The golden hues of autumn belong clearly to another category. [M. J. B.]

IDES, or IDEUS. In terminating Greek compounds = similar: as *petaloides*, like a petal.

IDIOGYNOUS. Not having a pistil.

IDIOTHALAMUS. Having a different colour or texture from the thallus; a term used among lichens.

IDOTHEA. A genus of *Liliaceæ*, from the Cape of Good Hope, allied to *Drimys*, but differing in the perianth being deciduous. It is also near *Uropetalum* and *Urginea*, but is distinguished from the former by the sepals being united at the base, forming a bell-shaped tube, and from the latter by the deciduous one-nerved perianth segments. They are herbs with scaly or more rarely coated bulbs. [J. T. S.]

IF (Fr.) *Taxus baccata* — NUCIFÈRE. *Podocarpus nuscifer*

IFE. An Indian name for *Sansevieria cylindrica*.

IGNAME. (Fr.) *Dioscorea sativa*.

IGNATIA. A genus described by the younger Linnaeus as belonging to the *Strychnos* family, but since suppressed by Mr Bentham, who has shown it to be composed of the leaves and flowers of a species of *Posoquerra*, and the fruits of a *Strychnos*, the former a plant of Guiana, the latter from the Philippines. The seeds are called by old writers, St. Ignatius' Beans, and are held up by them as a remedy against cholera. They are supposed to belong to *Strychnos multiflora*, but are quite unknown to modern botanists. [A. A. B.]

IGNEUS. Very lively scarlet, fiery red.

ILEODICTYON. A genus of phalloid *Gasteromycetes*, nearly allied to *Clathrus*, but distinguished from it by the hollow branches of the receptacle, which are, moreover, not porous. The gelatinous volva of *I. cibarium* was formerly eaten in New Zealand, before the English habits had gained ground, and was known by a name equivalent to Thunder-dirt. [M. J. B.]

ILEX. A genus of shrubs and trees belonging to the *Aquifoliaceæ*, inhabiting Europe, Asia, and America, and characterised by having an inferior calyx with small teeth; a corolla which is monopetalous but scarcely so, it being divided into deep spreading concave segments; stamens inserted upon the corolla and alternate with its segments; a four or five-celled ovary, with nearly sessile stigmas; and a berried fruit containing one-seeded nuts, the parts being all in fours or fives. The species are very numerous. *I. Aquifolium*, common Holly, employed so much for purposes of decoration at Christmas, and *I. paraguayensis*, Paraguay Tea, are the most remarkable.

*I. Aquifolium* is distinguished from other species by its peculiar smooth, wavy, shining, spinous leaves, and its short axillary many-flowered peduncles. The leaves are stated on good authority to be equal to

fevers. The root and bark are said to be deobstruent, expectorant, and diuretic, agreeably to which Haller recommends the juice of the leaves in jaundice. The berries

are purgative and emetic, six or eight being sufficient, it is said, to produce the latter effect. The beautiful white wood is much used for inlaying, and birdlime is obtained from the bark. It has been stated recently by M. J. Pierre, that the young stems are gathered in Morbihan by the peasants, and made use of as a cattle-food from the end of November to April with great success. The stems are dried, and having been bruised are given as food to cows three times a day. They are found to be very wholesome and very productive of good milk, and the butter made from it is excellent. The common Holly is the badge of the Drummonds.

*I. paraguayensis* is characterised as a species by its perfectly smooth, ovate, lanceolate unequally-serrated leaves, and by having much-branched racemes of flowers, the subdivisions of which are somewhat umbellate, and by its slightly hairy calyx. The leaves of the Maté, the name by which it is known in South America, are from four to five inches long. The Maté occupies the same important position in the domestic economy of South America, as the Chinese tea does in this country, and it is calculated that it is consumed in that country to the extent of about 8,000,000 lbs. annually. It has been in use for about a century and a half, the practice having been adopted from the aboriginal people. The leaves are prepared by drying and roasting, not in the manner of Chinese teas, but large branches are cut off the plants and placed on hurdles over a wood fire until sufficiently roasted; the

roasting; and the Caa-Guaza or Yerva de Palos of the Spaniards, the whole leaf with the petioles and small branches roasted. It is prepared for drinking by putting a small quantity, about a teaspoonful, into a gourd or cup, with a little sugar; the drinking tube is then inserted, and boiling water poured on the Maté; when sufficiently cool, the infusion is sucked up through the tube. It has an agreeable, slightly aromatic odour, is rather bitter to the taste, and very refreshing and restorative to the human frame after enduring great fatigue. It is almost impossible for those accustomed to it to leave it off. It acts in some degree as an aperient and diuretic, and if taken in over-doses, it occasions diseases similar to those produced by strong liquors. It contains the same active principle as tea and coffee, called theine, but not their volatile and empyreumatic oils.

It is stated that *I. Gongonha* and *I. thezans* are also employed in Brazil as tea, and they are described in common with *I. paraguayensis* as being valuable diuretics and diaphoretics. The leaves of *I. paraguayensis* and several others are used by dyers; the unripe fruits of *I. Macoucoua* abound in tannin, and, bruised in a ferruginous mud, are used in dyeing cotton, acting something like galls. [B. C.]

**ILLAIREA.** A genus of *Loasaceae* from central America, of which the only species *I. canarinoides* is a climber, with much the habit and aspect of *Canaphora lateritia*, but having the ovate oblong keeled petals so arranged as to form a bell-shaped flower, bearing considerable resemblance to that of *Canarina*. The leaves are cordate or fiddle-shaped, deeply pinnatifid with toothed lobes, and furnished, as are the stems, with virulent stinging hairs; the flowers are nodding, borne on long axillary peduncles, and of a cinnabar or brick-red colour, with blue stamens. There are five concave half-boat-shaped nectary scales alternating with the petals, bearing on their back a couple of setae, and standing in front of the petals, two before each, long filiform staminodia, converging in a cone over the style, which has five hemispherical corpuscles at its base. Beyond this there is little besides the campanulate form of the corolla to separate *Illairea* from *Canaphora*. [T. M.]

**ILLECEBRACEÆ.** (*Paronychia*, *Herniaria*, *Knottwort*.) A natural order of dicotyledons belonging to Lindley's silenial alliance of hypogynous Exogens. Herbaceous or somewhat shrubby plants with opposite or alternate often clustered sessile stipuled leaves, and minute flowers; sepals three to five, distinct or ovuled; petals small, sometimes none; stamens opposite the sepals, if equal to them in number; ovary superior; styles two to five; seeds either numerous and attached to a free central placenta, or solitary and pendulous from a cord attached to a basal placenta; embryo curved in albumen. Natives of barren places chiefly in Europe and the north of Africa. Their properties

*Ilex paraguayensis.*

branches are then placed on a hard floor and beaten with sticks; the dried leaves are thus knocked off and reduced to a powder, which is collected, made into packages, and is ready for use. There are three sorts known in the South American markets: the Caa-Guys, which is the half-expanded leaf-buds; the Caa-Miri, the leaf torn from its midrib and veins, without

are astringent. There are thirty-one known genera, and about one hundred and twenty-five species. Examples: *Illecebrum*, *Paronychia*, *Spergula*. [J. H. B.]

**ILLECEBRUM.** A genus of *Illecebraceae* containing a single species, *I. verticillatum*, found over the greater part of Europe, though very rare in Britain, and only occurring in the extreme south-west. It is a small branched prostrate smooth annual, with ascending branches, crowded with pairs of obovate leaves, and bearing axillary clusters of flowers forming false whorls; these are small, white, and shining, from the dry white thickened calyx segments. [J. T. S.]

**ILLICIUM.** A limited genus of *Magnoliaceae*, found in the south-eastern parts of the United States, Japan, Southern China, and the Khasia mountains. They are ever-green shrubs or low trees, with smooth entire leaves, exhaling when bruised a strong odour of aniseed, owing to the volatile oil contained in minute pellucid dots, which may be seen by means of a lens. Their flowers are borne singly or in threes from the sides of the branches, usually of a yellowish colour, except in one species where they are dark purple; they have a calyx of three or six sepals, coloured in the same manner as, and scarcely distinguishable from the petals, which vary in number from nine to thirty, and are arranged in several series, the innermost ones being the smallest; the stamens are numerous, and the ovaries, varying from six to eighteen, are crowded together in a circle. The fruit resembles a star, consisting of a variable number of one-seeded flattened cells arranged round a central axis.

*Illicium anisatum.*

*I. anisatum*, the Star or Chinese Anise, the Badiane of the French, is a shrub growing eight or ten feet high. It is found in China, and derives its name of Star Anise from the stellate form and odour of its fruit, which is about an inch in diameter. This fruit forms a considerable article of commerce amongst Asiatic

nations, and is likewise sent to Europe, though not in very large quantities. In China, Japan, India, and elsewhere in Asia, it is commonly used by cooks as a condiment in the preparation of food, and it is also chewed in small quantities after each meal, both for the purpose of sweetening the breath and as a promoter of digestion, while the native physicians prescribe it as a stomachic and carminative. In France it is reputed to be employed as the flavouring ingredient of *Anisette de Bordeaux*. Its pungent aromatic flavour and odour, which bear a strong resemblance to those of the common anise but rather sweeter and softer, is due to the presence of a volatile oil, which is obtained from it by distillation, and is said to be substituted for genuine oil of anise.

*I. religiosum*, a Japanese species, was formerly confounded with the Chinese. It is a small tree about the size of a cherry tree, and is held sacred by the Japanese, who form wreaths of it with which to decorate the tombs of their deceased friends, and they also burn the fragrant bark as incense before their deities. Their watchmen likewise use the powdered bark for burning in graduated tubes in order to mark the time, the bark consuming slowly and uniformly. The leaves are said to possess poisonous properties; while in Alabama those of *I. floridatum* have the same reputation, and the plant has hence acquired the name of Poison-bay. [A. S.]

**ILLIGERA.** An apetalous genus of *Exogens*, regarding the station of which there is much difference of opinion. It consists of climbing shrubs, natives of Java, having alternate coriaceous leaves which are ternate, and one tropical African species in which they are quinquefoliate. The flowers are hermaphrodite in axillary panicles; the calyx superior, coloured, ten-lobed, the lobes being disposed in two rows; the stamens five, opposite the outer row, having glands at their bases; the anthers open by valves which turn upwards; and the ovary is one-celled. The fruit is four-sided with four unequal wings at the angles, and the single pendulous seed has the cotyledons spirally twisted together. The nearest affinity of this genus is with *Gyrocarpus*, from which it differs in its climbing stem, and in having wings on the sides of its fruit. These two genera have been considered as the type of a distinct family under the name of *Illigerae* or *Gyrocarpeae*, but are very near both *Combretaceae* and *Lawsoniaceae*, with the former of which they have been combined. [B. G.]

**ILLIGEREE.** A small order of *Exogens*, or suborder of *Combretaceae*, from which latter the plants referred to it are distinguished mainly by their recurved anther valves, in which respect they resemble *laurels*. Also called *Gyrocarpeae*. [J. H. B.]

**ILLIEPIE or ILLIPE.** *Bassia longifolia*.

**IMANTOPHYLLUM.** This name, under the form of *Imatophyllum*, subsequently changed by Sprengel to *Himantophyllum*,

was originally applied to the amaryllidaceous plant called *Clivia*, which latter name has superseded it; and its author, Sir W. J. Hooker, has since transferred it to a related Natal plant of great beauty, which he calls *I. miniatum*. This plant forms a stemless herb, with thick fleshy roots, ample dictichous lorate leaves embracing each other at the base, and a tall plane-convex scape bearing an umbel of many large showy flowers of a bright orange-tinted vermillion. These consist of a six-leaved perianth, with a very short tube and broad obovate-lanceolate nearly equal segments, spreading into a broadly campanulate form; there are six stamens with thickish subulate filaments, and a thick slightly decurved style with a trident stigma. The seeds are bulbiform, about the size of a horsebean. [T. M.]

**IMBERBIS.** Having no hairs.

**IMBRICATED.** When bodies overlap each other like tiles on a roof.

**IMBRICARIA.** A genus of sapotaceous trees natives of Bourbon, Mauritius, &c. The flowers have eight sepals in two rows; a corolla divided into several segments, arranged in three rows; sixteen stamens, eight of them fertile and eight sterile; and a fleshy fruit, with eight one-seeded cells. The fruits of *I. malabarica* and *I. maxima* are edible. [M. T. M.]

**IMHOFFIA.** A genus of *Amaryllidaceæ*, allied to *Brunsvigia*, and consisting of Cape bulbs characterised by the flowers having a very short straight tube and a spreading or reflexed limb of six nearly equal segments, six stamens with equal filaments enlarged at the base, and a straight style with an obtuse three-cornered stigma. They have filiform leaves, and a solid scape bearing at top a many-flowered umbel of white flowers, often marked with red. The name was originally intended for *Amaryllis marginata*, a plant which is now referred to *Nerina*. [T. M.]

**IMMARGINATE.** Having no rim or edge.

**IMMEDIATE.** Proceeding directly from a part, without the intervention of any other part; as the flower-stalks of a raceme.

**IMMOBILE, IMMOBILIS.** Immoveable; that is to say, not having a free motion on the part which bears it; as many anthers.

**IMMORTAL FLOWER.** A name applied to the various common species of *Helichrysum*, *Antennaria*, *Gnaphalium*, &c.

**IMMORTELLE** (Fr.) *Xeranthemum*; also *Helipterum* and *Helichrysum*, especially *H. orientale*; also the wood of *Erythrina glauca*. — **BLANCHE** or **DE VIRGINIE**. *Antennaria margaritacea*. — **DE LA MAL-MAISON**. *Helichrysum bracteatum*. — **JAUNE**. *Helichrysum orientale*. — **VIOLETTE**. *Gomphrena globosa*.

**IMPARIPINNATE.** When the petiole

of a pinnate leaf is terminated by a single leaflet.

**IMPATIENS.** A genus of *Balsaminaceæ*, chiefly found in India, though a few species occur in Europe and North America. They are generally glabrous herbs with thick succulent stems enlarged at the joints, where the alternate undivided leaves are given off. The flowers are axillary, often handsome, and so very irregular that considerable difference of opinion exists as to which parts belong to the calyx and which to the corolla. The view taken by Kunth is by far the most probable, namely, that two outer small scale-like leaves, a large hood-shaped and spurred coloured lower sepal, and an upper coloured portion composed of two united together so as to appear but one, form an irregular imbricated calyx of five sepals. Within this there are two pairs of petals, unequally cleft nearly to the base. The stamens are five in number, with the filaments united above; and in the centre is the five-celled ovary with a sessile lobed stigma. The capsule is oblong, subcylindrical, or with five blunt angles. The valves separate and roll up when touched after the seeds are ripe. *I. Balsamina* is the much-cultivated Garden Balsam, which readily becomes double, and of which the flowers are very variable in colour, a native of India. *I. Noli-tangere*, the Touch-me-not, is found apparently wild in Britain, and is frequent in Europe; the flowers in this species are yellow. [J. T. S.]

**IMPERATORIA.** *Peucedanum*.

**IMPERIALE.** (Fr.) *Fritillaria imperialis*.

**IMPLEXOUS.** Entangled, interlaced.

**IMPREGNATION.** The fertilisation of the ovule by the pollen-tubes.

**IMPUBERA** (ÆTAS). The period of maturity in fruit anterior to the fertilisation of the ovules.

**INÆQUALIS.** Of unequal or dissimilar size.

**INÆQUILATERAL, INÆQUILATERUS.** When the two sides of a figure are not symmetrical; as the leaf of a *Begonia*.

**INANIS.** Empty, not containing anything; or merely filled with a loose spongy substance.

**INANTHERATE.** Bearing no anther; applied to sterile filaments or abortive stamens.

**INAPERTOUS.** Not opened, although its habit is to open.

**INCANESCENT.** Having a hoary or grey aspect, because of the presence of hairs upon the surface.

**INCANUS.** The same as Canus; hoary.

**INCARNATUS.** The same as Carneus.

**INCARVILLEA.** A genus of *Bignoniaceæ* containing now only a single species

the plants formerly referred to it being placed in new or neighbouring genera. It is an erect glabrous herb from China, having the habit of *Argyria*, with alternate bipinnatisect leaves, and large scarlet flowers in terminal racemes. [W. O.]

**INCENSE.** Frankincense, the modern Oilbanum.

**INCENSE TREE.** *Ikica guianensis*.

**INCENSE WOOD.** *Ikica heptaphylla*.

**INCISED, INCISUS.** Regularly divided by deep incisions. Hence *inciso-serratus*, having deep slashed serratures; *inciso-dentatus*, having slashed toothings, &c.

**INCLINING.** Falling back considerably from the horizontal line.

**INCLUDED.** Enclosed in anything.

**INCOMPLETE.** Deficient in some of its parts, as a flower without corolla, or a calyx with only a part of its sepals.

**INCONSPICUOUS.** Small in size, not readily observed.

**INCRASSATE.** Thicker than usual in proportion to its area; as the leaves of the houseleek.

**INCRUSTATE.** A term applied to seeds which grow so firmly to their pericarp as to appear to have but one integument. Also coated with earthy matter.

**INCUBOUS.** A name employed in descriptions of *Jungermanniaceæ* in contradistinction to succubous, to indicate that the leaves are imbricated over each other from the base towards the apex, whereas in succubous leaves they are imbricated in a contrary direction. [M. J. B.]

**INCUMBENT.** Said of an embryo when its radicle is folded down upon the back of the cotyledons.

**INCURVED, INCURVUS, INCURVATE.** Curved inwards.

**INDEHISCENT.** Not splitting in a definite manner when ripe.

**INDIAN HEART.** *Cardiospermum Corindum*.

**INDIAN SHOT.** *Canna*.

**INDIA-RUBBER.** The inspissated juice of *Ficus elastica*, *Euphorbia elastica*, *Hevea*, and other plants: see CAOUTCHOUC.

**INDIGO.** A blue dye yielded by several plants, as *Indigofera tinctoria* and *argentea*, *Wrightia tinctoria*, *Marsdenia tinctoria*, *Gynema tingens*. —, **BASTARD.** *Amorpha fruticosa*. —, **CHINESE.** *Isatis indigotica*. —, **EGYPTIAN.** *Tephrosia Apollinea*. —, **FALSE.** An American name for *Baptisia*. —, **INDIAN.** *Indigofera tinctoria*. —, **NATIVE.** *Isatis tinctoria*. —, **WEST INDIAN.** *Indigofera Anil*. —, **WILD.** *Baptisia tinctoria*.

**INDIGO-BERRY.** *Randia latifolia*.

**INDIGOFERA.** A very extensive tropical or subtropical genus of leguminous

plants, valuable on account of the blue colouring material, called Indigo, afforded by several of the species, of which upwards of two hundred are described, the greater number belonging to the African continent, but abounding also in both America and Asia, and a few extending to Australia. They are either annual or perennial herbaceous plants or shrubs, and have pinnate leaves, which, however, are occasionally reduced to three or one leaflet only. The flowers are usually of a rose-purplish or bluish colour or white, and are borne in racemes from the angles of the leaves; they have a broad five-toothed calyx, a papilionaceous corolla having the upper petal curved backwards; and ten stamens, one of which is free. The fruit is a cylindrical or four-sided, straight or curved pod, containing numerous (rarely one or two) angular seeds.

*I. tinctoria*, the species most commonly cultivated, is a native of the East Indies and other parts of Asia, but it has been introduced into and become naturalised in Africa and America. It is a shrubby plant growing about three or four feet high, having oval or inversely egg-shaped leaflets, and long narrow pods. *I. Anil*, the

*Indigofera tinctoria*.

West Indian Indigo, is a larger plant, attaining a height of five or six feet, and is a native of the West Indies and America, from Carolina to Brazil, but has become naturalised in Asia and Africa. Its leaflets are of a spatulate form, and its pods short and thick.

The use of Indigo as a dye is of great antiquity. It is mentioned by Dioscorides and by Pliny, and is supposed to have been employed by the ancient Egyptians. It was not, however, much used in Europe till about three centuries ago, and for a long time it experienced considerable opposition on account of its interference with the domestic manufacture of wool (see ISATIS), and in several European countries

edicts were issued prohibiting its use by dyers, and stigmatising it as the devil's dye. As met with in commerce at the present day, Indigo usually consists of cubical cakes, measuring between two and three inches. It is prepared by throwing bundles of the fresh-cut plants into shallow vats and covering them with water, care being taken to keep them under the surface. After steeping for ten or twelve hours the liquid is run off into another vat and beaten with sticks or bamboos from one and a half to three hours, in order to promote the formation of the blue colouring matter, which does not exist ready formed in the tissues of the plant, but is formed by the oxidation of other substances contained in them. The colouring matter is then allowed to settle, the precipitation being accelerated by the addition of a small quantity of clean cold water or lime-water, and the supernatant liquor drawn off and thrown away, while the deposited matter is put into a boiler and kept at the boiling point for five or six hours. After this it is spread upon frames covered with cloth, and allowed to drain for twelve or fourteen hours, and when it is sufficiently solid it is pressed, cut into cubes, stamped and dried for the market. Our imports of Indigo average about 68,000 cwt. annually, the greatest part coming from the East Indies, but a large portion is re-exported to various European countries, the consumption in the United Kingdom not being more than about 13,000 cwt. per annum. [A. S.]

**INDIGOTICUS.** The deepest blue.

**INDIGOTIER.** (Fr.) *Indigofera*.

**INDIVISUS.** Not separated into other parts.

**INDRAJAW, INDURJAW.** Indian names for the bitter seeds of *Wrightia antidysenterica*.

**INDUGA.** An Indian name for the Clearing-nut, *Strychnos potatorum*.

**INDUMENTUM.** The hairy covering of plants, of whatever kind.

**INDUPLICATE, INDOPLICATIVE.** Having the margins bent abruptly inwards, and the external face of these edges applied to each other without any twisting.

**INDURASCENT.** Hardening by degrees, as the permanent petioles of a tragacanth bush.

**INDUSIUM.** A name given to the immediate covering of the tuft of capsules or sporangia in ferns. Sometimes the sori are quite naked, the cuticle being simply ruptured by the protrusion of the young fruit. Sometimes, however, the cuticle is lifted up, and forms a covering of various shapes, being sometimes lateral, sometimes target-shaped, sometimes spherical, &c. In other cases the indusium appears to be a distinct growth arising from the tip or side of a vein. The border is either entire or ciliate. The indusium may be variously,

seated even in the same genus, or again it may be almost obsolete, or, as in *Hypolepis tenuifolia*, be quite membranous or herbaceous, and in the latter case partaking more of the nature of the frond itself. In *Pisopeltis*, the indusium is replaced by a number of peltate scales, which, however, have no real relation to a true indusium. In genera like *Hymenophyllum*, where the fruit is produced at the tip of the protruding costa, the bivalvate or cup-shaped indusium is either formed of the frond itself, or springs from the excurrent costa. Sometimes the sori are covered, not only with an indusium, but with a portion of the turned-up edge of the leaf. The annulus of some fungals also bears the same name. [M. J. B.]

**INDUVIÆ** (adj. **INDUVIATE**). Withered leaves remaining upon a stem, and clothing it.

**INENCHYMA.** Fibro-cellular tissue, that is to say, cells having the appearance of spiral vessels.

**INERMIS.** Destitute of any kind of spines or prickles.

**INFERIOR.** Growing below some other organ; thus, an inferior calyx grows below the ovary, whilst an inferior ovary grows, or seems to grow, below a calyx.

**INFLATED.** Thin, membranous, slightly transparent, swelling equally, as if inflated with air.

**INFLORESCENCE.** The manner in which the flowers are arranged.

**INFOSSOUS.** Sunk in anything, as veins in some leaves, leaving a channel, however.

**INFRACTOUS.** Curved inwards.

**INFUNDIBULAR, INFUNDIBULIFORM.** Funnel-shaped.

**INFUNDIBULI-CAMPANULATE.** Between funnel-shaped and bell-shaped.

**INGA.** A very extensive genus of leguminous plants, of the section *Mimoseæ*, comprising nearly one hundred and fifty species, all of which are natives of the warmer parts of South America, principally of Brazil and Guiana. They form large shrubs or trees, sometimes growing fifty or sixty feet high, and have pinnate leaves composed of from two to five or six pairs of largish leaflets, bearing a gland on the stalk between each pair, the stalk being frequently winged or leaf-like. The flowers are usually white or yellowish, and borne in variously shaped spikes or in nearly globular heads, growing singly or in clusters from the angles of the leaves. They are generally all perfect, and have a tubular calyx, and a tubular or funnel-shaped corolla, enclosing an indefinite number of stamens, which are twice or several times the length of the corolla, and joined together at the bottom. The pods are flattened or roundish, with thickened

edges, and the seeds are enveloped in a sweet, generally white pulp.

*J. Feuillee*, a native of Peru, is cultivated in the gardens about Lima, where the inhabitants call it Pacay, and commonly eat the white pulp of its pods. Its leaves have winged stalks, and are composed of three or four pairs of oval-oblong leaflets, which are smooth, and tapered towards both ends. Its pods are sometimes as much as two feet long.

*J. spectabilis* is a large showy tree, called Guavo real in the Isthmus of Panama, where it is commonly cultivated on account of its eatable pods, as it also is in some parts of New Grenada. The leaves consist of two pairs of smooth and shining, egg-shaped, pointed leaflets, the upper pair being much the largest. The flowers are pure white, succeeded by numerous large pods, two or more feet long, and three inches broad, which, in consequence of their weight, are pendulous from the branches. The white pulp surrounding the seeds in the pods of this and other species of the genus, has a pleasant sweet flavour, and is much eaten by the inhabitants of Panama.

*J. vera*, a West Indian tree, common in Jamaica and Trinidad, has leaves with winged stalks, and four or five pairs of elliptical lance-shaped leaflets. Its pods are curved like a reaper's sickle, and measure about six inches long; the pulp contained in these is sweet, but like that of several other species, it possesses purgative properties. [A. S.]

**INGENHOUIZIA.** A name applied to a Mexican shrub, described as being like a *Gossypium*, and with yellow flowers, passing into red, and numerous stamens in one parcel. (It is imperfectly known. Bentham and Hooker suggest its identity with *Tournefortia*: which see.) [M. T. M.]

**INK-BERRY.** An American name for *Prinos glaber*.

**INNATE.** Adhering to the apex of a thing, as the anther to the apex of a filament.

**INNOVATIONS.** A name given to the new branches of mosses, which are produced after the fructification has been perfected, or after the first complete growth where the plants remain barren. A difference of habit may arise from their suppression or peculiar growth. In *Bryum*, for example, the innovations are produced from the floral apex, but in *Leptobryum* none are produced. The little bud-like tufts which bear the male organs in some species of *Hypnum* and *Dicranum*, which are attached very slightly to the stem, must be distinguished from true innovations. [M. J. B.]

**INOCARPUS.** This genus consists of three species, large trees, natives of the islands of the Pacific and Indian Archipelago, with alternate unifoliate leaves, and yellow flowers in axillary spikes. They have a tubular calyx, arched at the back, and bifid; five petals united to form a

short tube; ten stamens in two rows, the upper attached to the mouth of the corolla tube and the lower to its base; and a one-celled ovary with a nearly sessile stigma. The fruit is a fibrous pod with one seed. The genus was for some time referred to the daphnaceous family, its petals being regarded as a calyx, but it is now known to belong to *Cesalpiniaceae*, a section of the leguminous family. The seeds of *J. edulis* are much prized by the natives of the Indian Archipelago, and in Machian they almost live upon them. They are, however, not palatable food, but when boiled or roasted in ashes are sweet. They are less agreeable than the chestnut, and are not suited to weak stomachs. [B. C.]

**INOCULATION.** An ancient term for the operation of budding.

**INSECT FUNGI.** Many animals are subject to attacks of fungi, but none more so than insects, whether in a perfect state or in the condition of caterpillar or chrysalis. Some of these fungi are very minute, and often of little interest except from the ravages they commit amongst bees, silkworms, &c.; but others, on the contrary, are large and sometimes brilliantly coloured, and attract notice from the proportion which they bear to the insect on which they grow. These belong to the genus *Cordyceps*, to which head we refer for particulars. Amongst them one of the most remarkable is the species which is so often brought home from New Zealand, where it is produced in abundance on the caterpillar of *Hepialus virescens*. The white mould which oozes out as it were between the abdominal rings of flies in autumn, is in all probability a form of one of the curious productions which we shall notice under *Saprolegnia*. [M. J. B.]

**INSERTION.** The manner in which one part is inserted into or adheres to, or originates from another.

**INTEGER.** Properly speaking, this means having no kind of marginal or other division; but sometimes it has been used to indicate not pinnatifid, and also nearly destitute of marginal division.

**INTEGERRIMUS.** Perfectly free from division of the margin or other part.

**INTEGRA VAGINA.** A sheathing petiole which forms a continuous tube, not slit on one side, as in sedges.

**INTEGUMENTA FLORALIA.** The calyx and corolla.

**INTER.** In composition = between: as *interfoliaceus*, placed between leaves.

**INTERCELLULAR.** Anything interposed between the cells or tubes of tissue.

**INTERMEDIUS.** Standing between two bodies in a different row, as petals which they alternate with sepals. Also half-way between one thing and another.

**INTERNODE.** The space which intervenes between two nodes

**INTERRUPTED.** When any symmetrical arrangement is destroyed by local causes; a leaf is interruptedly pinnated when some of the pinnae are much smaller than the others, or wholly wanting.

**INTERVENIUM.** The space of parenchyma between the veins.

**INTEXINE.** That coating of the pollen which is next the extine or outer crust, and above the intine or inner lining.

**INTINE.** The innermost lining of the shell of a pollen grain.

**INTORTUS.** Twisted upon itself.

**INTRA.** Placed within anything; as *intrafoliaceus*, placed within the axil of a leaf.

**INTRARIUS.** Turned inwards; that is to say, towards the centre of a flower.

**INTRAVALVULAR.** Placed within valves, as the dissepiments of many crucifers.

**INTRICATE.** Entangled.

**INTROCURVUS, INTROFLEXUS, INTROFLEXED.** Curved inwards.

**INTRORSE.** Turned towards the axis to which it appertains; as an anther when its valves face the centre of a flower.

**INTROVENIUM.** Hidden-veined; when veins are so much buried in parenchyma that they are not visible on external inspection.

**INTRUSUS.** Pushed inwards; as when the base of a fruit is so concave as to seem as if pushed inwards by the peduncle.

**INULA.** A genus of composite plants, having the outer or ray florets strap-shaped and containing pistils only, while the central florets are tubular and contain both pistils and stamens; the anthers have two bristles at their base; the pappus consists of rather rough hairs, arranged in a single row; and the involucre consists of numerous overlapping scales, but the receptacle is devoid of scales. The species are numerous and occur throughout Europe and central Asia. *I. Helentum*, Elecampane, occurs spontaneously in this country, but having long been cultivated in herb gardens, it is considered that it may originally have been derived from such a source. It is a perennial plant with a stem from three to five feet high; large saw-toothed leaves tapering to a stalk, the upper ones smaller, and embracing the stem; and large heads of yellow flowers. The root has an aromatic camphor-like taste, due to the presence of a crystalline substance called helenin, allied in chemical constitution to crocote. It also contains a quantity of starchy material, called inulin, which differs from ordinary starch in being coloured yellow by iodine. Elecampane was formerly much used as an aromatic tonic, and as a stimulant of all the secreting organs, likewise in coughs, dyspepsia, &c. *I. Compta*, a common hedge plant in some

parts of England, grows to the height of two to three feet, and has rough leaves, and numerous small flower-heads disposed in a corymb. This plant, called Ploughman's Spikenard, has a somewhat aromatic odour. Its leaves are occasionally gathered in place of those of *Digitalis*, from which they may be distinguished by their roughness and their smell. [M. T. M.]

**INUNCANS.** Said of surfaces covered with little hooked hairs, as the leaves of some species of *Gallum*.

**INUNDATE.** Flooded. Sometimes covered with water, sometimes dry.

**INUS.** A termination expressing the quality of resemblance, as *calycinus*, like a calyx in position, in colour, &c.; it also expresses augmentation, as *calycinus*, having a large calyx.

**INVERTED.** Having the apex in an opposite direction to that of some other thing; as many seeds.

**INVERTENTIA FOLIA.** Leaflets which in their sleep hang downwards, but touch by their upper surfaces.

**INVOLUCEL, INVOLUCELLUM.** A diminutive involucre; a secondary involucre usually not containing more than one or two flowers.

**INVOLUCRAL.** Of or belonging to an involucre.

**INVOLUCRATE.** Having an involucre.

**INVOLUCRE, INVOLUCRUM.** A ring or rings of bracts surrounding several flowers. Also the peridium, volva, or annulus of some fungi. Also the cup-formed external indusium of some ferns.

**INVOLUCRARIA.** A genus of *Ocuvbitaceae*, consisting chiefly of Indian species, nearly allied to *Trichosanthes*, but having the segments of the corolla entire, and the bracts of the racemes of male flowers large, leafy, concealing the flowers before their expansion. [M. T. M.]

**INVOLUTE, INVOLUTIVE.** When edges are rolled inwards on each side, as the leaf of the apple.

**IOCHROMA.** A genus of South American shrubs belonging to the *Solanaceae*, deriving its name from the handsome violet or purple-coloured flowers. The calyx is tubular, somewhat distended, with five unequal teeth, and becomes larger as the fruit ripens. The corolla is tubular, much longer than the calyx, and conceals the stamens. The fruit is succulent, two-celled, many-seeded, enclosed in the bladderly calyx. *I. subulorum* and *I. lanunculatum* are greenhouse shrubs. [M. T. M.]

**IODINA.** A genus of *Claoceae* [or *Santaceae*, according to Bentham and Hooker], a South American shrub with rhomboid leathery leaves, spinous at the angles and apex, and subsessile flowers in axillary glomerules, having a five-cleft calyx, five petals on a

fleshy disk, five stamens, and a two-celled ovary immersed in the disk. [J. T. S.]

**IONE.** A genus of epiphytal orchids from the Himalayas, numbering seven species. They are tufted plants, three to nine inches high, with pseudobulbs bearing a single coriaceous leaf, and a radical flower-scape ending in a spike of small white or violet flowers. The lip is narrow like the sepals, and there are four pollen-masses attached to two distinct glands. Dr. Lindley remarks that with the habit of *Bolbophyllum*, this genus unites the glands and pollen-masses of *Angraecum*. Its long membranous two-lipped calyx, dwarf petals, and large lip with fleshy axis usually extended into a dagger-shaped point, are very unlike anything belonging to the neighbouring genera. He also notes that it forms a transition from *Vanda* to *Malacidae*. [A. A. B.]

**IONIDIUM.** An extensive genus of *Violaceae*, whose species are natives for the most part of subtropical America. Their flowers are characterised by the sepals not being extended at the base; by the five unequal petals, one of which is much larger than the rest; and by the detached stamens. The roots of some of the species contain emetin, and may be used, therefore, instead of *Ipecacuanha*. What is called White *Ipecacuanha* consists of the roots of *I. Ipecacuanha*. Another species, famed in Peru for the cure of tubercular elephantiasis, is *I. microphyllum*, whose roots act powerfully as emetics and purgatives. The root of *I. suffruticosum*, an Indian plant, is likewise used medicinally in diseases of the urinary organs, and the leaves as external applications. [M. T. M.]

**IONOPSIDIUM.** A genus of *Cruciferae*, containing extremely small Portuguese and Algerian annual plants, with scarcely any stem, numerous long-stalked small roundish root leaves, and scape-like flower-stalks, each bearing a small white or purplish flower. The pouch is roundish, laterally compressed, slightly notched at the apex, with keeled wingless valves more turgid than is usual among the genera, in which the partition is in the narrowest diameter of the pouch, whence the plant used to be placed in *Cochlearia* though really allied to *Capsella*. [J. T. S.]

**IONOPSIS.** A small genus of elegant little epiphytal orchids of tropical America. They are stemless plants, having small pseudobulbs emitting wiry roots, a few lance-shaped leaves, and an erect slender flower-scape, ending in a panicle of numerous small pink or white flowers, resembling those of a violet in form—whence the generic name. The sepals and petals are small and connivent; the lip large, fan-shaped, two-lobed at the apex, and slightly spurred at the base; and there are two pollen-masses attached to the end of a linear caudicle with an oblong gland at the base. Their delicate flowers remain for a long time expanded without fading. [A. A. B.]

**IPÉBRANCO.** *Patagonula vulneraria*.

**IPECAC, AMERICAN.** *Gillenia stipitacea*. —, WILD. *Euphorbia Ipecacuanha*.

**IPECACUANHA.** The root of *Cephaelis Ipecacuanha*. —, BASTARD. *Asclepias curassavica*. —, BLACK, or PERUVIAN. *Psychotria emetica*. —, FALSE BRAZILIAN. *Ionidium Ipecacuanha*. —, GUAYANA. *Boerhaavia decumbens*. —, STRIATED. *Psychotria emetica*. —, UNDULATED. *Richardsonia scabra*. —, VENEZUELA. *Sarcostemma glaucum*. —, WHITE. *Ionidium Ipecacuanha*; also *Richardsonia scabra*. —, WILD. *Asclepias curassavica*.

**IPECACUANHA DES ALLEMANS.** (Fr.) *Vincetoxicum officinale*.

**IPE-TABACCO, or IPEUNA.** Names given to certain hard-wooded species of *Bignonia*, in Brazil.

**IPHIGENIA.** A genus of *Liliaceae* from India, with the habit of the Australian genus *Angulularia*, from which it differs by its introrse anthers, and styles united at the base. They are glaucous herbs, with coated bulbs, erect leafy stems, and a three-flowered or racemose inflorescence; the perianth deciduous coloured with linear divisions spreading like a star, the filaments hairy, the style with three stigmas. [J. T. S.]

**IPIE.** *Buxia latifolia*.

**IPO.** A Malay name for the Uras poison.

**IPOMCEA.** A large genus of *Convolvulaceae*, widely distributed over all warm climates, with a few species extending into North America, and into extratropical Africa and Australia. They are twining prostrate creeping or rarely low and erect

*Ipomoea batatoides.*

herbs, occasionally woody at the base, very rarely shrubby, with entire, lobed, or divided leaves, and generally large and showy flowers in the axils of the leaves, in small cymes, rarely solitary. The flowers have a calyx of five sepals; a campanulate or tubular corolla with a spreading entire or angular limb, rarely deeply lobed; five

included stamens; a two or three-celled ovary with two ovules in each cell; and a slender style with a bilobed stigma, the lobes capitate.

*Ipomœa* is frequently cultivated as an ornamental plant because of its showy flowers, but it derives its chief importance from the medicinal properties which many of its species possess. These depend chiefly on an acrid juice which abounds in their roots, and which has a strongly purgative quality arising from the presence of a peculiar resin. Sometimes sugar and starch replace the resin, and a valuable edible root is obtained; this is remarkably the case in the allied genus *Batatas*, the root of one species of which is the sweet potato. Although the best jalap is obtained from *Esogonum Purga*, yet many species of *Ipomœa* supply it, though of an inferior quality. *I. Turpethum*, a native of India and the islands of the Pacific Ocean, is employed by the natives as a common purgative, and although the resin is more diluted than in the true jalap, it is free from the nauseous taste and smell of that drug. The Mechameck of the North American Indians is *I. pandurata*. Its powdered root acts like rhubarb, and has also some reputation as a diuretic. The root of the South American *I. batatoides* has sufficient of the purgative resin to cause it to be employed. Scammony, it is said, can be obtained from *I. tuberosa*, the Spanish Arbour Vine of Jamaica. *I. sensitiva* is remarkable for the irritability of its corolla. [W. C.]

**IPOMOPSIS.** A subgenus of *Gilia*, comprising those species which have alternate divided leaves, flowers solitary or somewhat clustered, and a corolla tube very much longer than the calyx. See *GILIA*. [C. A. J.]

**IPRESINE.** A genus of *Amaranthaceæ*, natives of tropical and subtropical America (a single species reaching as far north as Ohio), and also of Australia. They are herbs with opposite stalked leaves, and small scarious white flowers in lax panicles, or dense heads, or spikes. The flowers are often polygamous, or dioecious by abortion. The fruit is a globular indehiscent utricle. [J. T. S.]

**IRIARTEA.** A genus of palms, from which have recently been separated *Socratea*, *Iriartella*, *Catobastus*, &c. The wax palm (*Ceroxylon*), which has been combined with it by some botanists, is here kept distinct. As now defined, *Iriartea* consists of five species, one of which is a native of Peru, and the others of the banks of the Amazon river. All of them are tall-growing plants, some of them attaining a height of sixty or eighty feet, or even higher, and they are frequently elevated above the conical mass of cylindrical roots, which gives them a most remarkable appearance. The stems are smooth, and marked with distant circular scars, generally almost cylindrical, but occasionally swollen or bulged out towards the top. They bear a

crown of large pinnate leaves, the lower part of the stalks of which form a cylindrical sheath round the top of the stem; the leaflets are somewhat trapezoid in form, and jagged on one side. The flower-spikes are pendulous from below the leaves, and have several spathe, the innermost of which completely encloses them while young, but eventually splits open; both sexes of flowers are borne on the same spike. The fruit is roundish or egg-shaped, and contains a single seed.

*I. coralliza*, the Pashuba or Paxluba palm of Brazil, is the tallest-growing species, and its cone of roots is sometimes so high that a man can stand in the centre, with the tall tree above his head. These aerial roots, being covered with little asperities, are commonly used by the Indians as graters, whilst the hard outer wood of the stem is employed for various portions of their houses, and likewise exported to the United States for making umbrella handles. [A. S.]

**IRIARTELLA.** A small South American palm, formerly called *Iriartea setigera*. It differs greatly in general appearance from the *Iriarteas*, which are all tall stout-growing palms, whilst this seldom grows higher than eighteen or twenty feet, and has a perfectly straight cylindrical trunk scarcely more than an inch thick. The flowers also differ in the males having a small rudimentary pistil in the centre of the fifteen stamens, whilst the females have no steric stamens, containing only a three-celled ovary. The Indians on the Amazon and Rio Negro, where this palm grows in the underwood of the forests, use its slender stems for making their gravatunas, or blow-pipes, the weapon commonly employed by them in the pursuit of game, and through which they blow small poisoned arrows with unerring accuracy and to a considerable distance. These gravatunas are usually from eight to twelve feet long, and have a bore of about a quarter of an inch. The stems, being soft and spongy in the centre, are easily bored by pushing a rod of hard wood through them, but in order to have the bore perfectly smooth, the Indians prefer splitting them in halves and carefully working a groove in each half, afterwards neatly reuniting and binding them round with the smooth shiving bark of a creeping plant. [A. S.]

**IRIDACEÆ. (Ensatæ, Iridæ.)** A natural order of monocotyledonous plants, belonging to Lindley's narcissal alliance of Endogens. Herbs with corms, rhizomes, or fibrous roots, and mostly with equitant leaves, and flowers in sheaths. Perianth six-parted, in two rows, sometimes irregular; stamens three, inserted at the base of the outer row of the perianth; anthers imbricate, opening on the back; style dividing into three petal-like portions, which bear the stigmas. Capsular fruit three-celled, three-valved, opening in a loculicidal manner; seeds with hard albumen. The plants are found both in warm and temperate regions; they abound at the Cape of Good

Hope. They have fragrant, stimulant, and acid qualities. The stigmatic processes of *Orocus sativus* yield saffron; the rhizomes of *Iris florentina* have the odour of violets. Upwards of 500 species in some fifty genera are known. Examples: *Iris*, *Gladiolus*, *Crocus*, *Ixia*. [J. H. B.]

**IRIDÆA.** A genus of the rose-spored *Algae*, belonging to the natural order *Cryptonemiaceæ*, distinguished by its flat frond, which is simple or loosely divided, bearing compound capsules, immersed in its substance. It is closely allied to *Gigartina*, and distinguished principally by the different position of the capsules, and the frond being less regularly cleft. *I. edulis*, which is easily known by its tough obovate dark-red frond, wedge-shaped at the base, is sometimes eaten like the common dulse, *Rhodomenia palmata*, and has been employed in the preparation of a dye, which is probably fugitive. The genus contains many species, most of which inhabit the Southern seas. [M. J. B.]

**IRIDINE.** (Fr.) *Vicusseuzia*.

**IRIO.** *Sisymbrium Irio*.

**IRIS.** A beautiful and extensive genus of perennial plants, with sword-shaped leaves, giving its name to the order *Iridaceæ*. They are very common in gardens, and one or two rank amongst our native wild flowers. The greater part have fleshy prostrate rhizomes, but some few are tufted, with fibrous roots, and a few others, as the English and Spanish *Iris* (see *KIRKOR*, *Supp.*), are

*Iris florentina*.

bulbous. The flowers are often large and very showy, being of bright or well-contrasted colours. The perianth is six-parted, with a short tube, but of the six segments the three outer are reflexed, and very frequently bearded at the base, and the three inner erect and very frequently smaller than the outer; there are three stamens inserted at the base of the outer segments, and having the anthers turned outwards; and

a triquetrous style with three petaloid dilated stigmas, each opposite the stamens, keeled above, and hollow beneath, having a transverse fold towards the front. The capsule is three or six-angled, and three-celled, containing numerous seeds. The species are found chiefly in the south of Europe and north of Asia, a few extending to North America and North Africa. Orris root, which has the odour of violets, and so much used for perfumery powders, &c., is the rhizome of *I. florentina*, a species with large white flowers. The root possesses carthartic and emetic properties; it is also sometime, chewed by persons who have offensive breath. The common native species, *I. Pseud-acorus*, found by the margins of ponds and streams, possesses astringent properties, and it is said that it may be used as a substitute for galls in making ink, as well as for dyeing black. Another species, *I. versicolor*, has purgative rhizomes. As garden flowers, the species of *Iris* rank amongst the most ornamental of hardy perennials. [T. M.]

**IRIS, PEACOCK.** *Vicusseuzia*. — **SCORPION.** *Iris alata*. — **SNAKESHEAD.** *Hernandactylus tuberosus*.

**IRIS.** (Fr.) The Fleur-de-lis, the emblem of France — **D'ALLEMAGNE.** *Iris germanica*. — **DES MARAIS.** *Iris Pseud-acorus*. — **DES PRÉS.** *Iris sibirica*. — **DEUIL.** *Iris austriaca*. — **GIGOT.** *Iris fatidissima*. — **JAUNE.** *Iris Pseud-acorus*. — **NAINE.** *Iris pumila*. — **PLU-NEUSE.** — *Moræa virgata*. — **TIGRÉE.** *Moræa sinensis*.

**IRIS-ROOT.** The same as Orris-root.

**IRONBARK-TREE.** *Eucalyptus resinifera*, and *Sideroxylon*.

**IRONHEADS.** *Centaurea nigra*.

**IRON-TREE.** *Siderodendron*.

**IRON-WEED.** *Vernonia*.

**IRONWOOD.** *Sideroxylon*; also the timber of several species of *Diospyros*, and of *Metrosideros vera*. — of Bourbon. *Cupania Sideroxylon*. — of Dutch East Indies. *Eusideroxylon Zuagerti*; also *Namta vera*, *Intsia amboinensis*, *Cassia florida*, *Meme-cylon ferreum*, *Stadmannia Sideroxylon*, *Dodonæa Walziana*, and *Sloëtia Sideroxylon*. — of Morocco. *Argania Sideroxylon*. — of New South Wales. *Argyrodendron trifoliatum*. — of Norfolk Island. *Notelæa longifolia*, and *Olea apetalæ*. — of North America. *Ostrya virginica*, and *Carpinus americana*. — of South Africa. *Olea undulata* and *capensis*. — of S. Sea Islands. *Casuarina equisetifolia*. — of Tasmania. *Notelæa lignastrina*. — **BASTARD.** *Xanthoxylon Pterota*. — **BLACK.** *Olea undulata*. — **JANATICA.** *Erythroxylon areolatum*. — **WHITE.** *Vepres lanceolata*.

**IRONWORT.** *Fidertitis*; also *Galeopsis Ladanum*. — **YELLOW.** *Galeopsis villosa*.

**IRREGULAR.** Having the parts which

constitute one series of a flower dissimilar in size or form.

#### IRUPÉ. *Victoria regia*.

**IRVINGIA.** A genus of *Simarubaceæ*, allied to *Soulamea* and *Amaroria*, but differing in habit, in the large disk under the ovary, and in several other characters. It consists of tropical African trees, entirely glabrous, with alternate entire leaves convolute in the bud, and leaving prominent rings on the branches as they fall off. The flowers are small and yellow, in terminal or axillary panicles. The drupaceous fruits of the two species known are edible, and much relished by monkeys; they are known under the name of Wild Mango. *I. Bartsii* is called **Dika**: which see.

**ISACANTHUS.** A genus of *Acanthaceæ*, containing a single species from Africa. It is a branching shrub, with entire leaves, and white flowers in few-flowered terminal spikes. The calyx is five-parted, the corolla has a slender tube, and a limb consisting of a single unequally five-lobed lip, and there are four exserted stamens. [W. C.]

**ISACHNE.** A genus of grasses belonging to the tribe *Panicææ*, now included by Steudel in *Panicum*. [D. M.]

**ISANTHERA.** A genus of *Cyrtandraceæ*, containing a single species a native of India. It is an herbaceous plant, with an erect stem, obovato-cuneiform acute leaves, and flowers in axillary clusters. The flowers are polygamous. The hermaphrodite ones have a five-cleft calyx, a rotate corolla, four or five stamens, and one-celled ovary. The female flowers want the corolla. This genus has the flowers of *Platystemma* conjoined to the habit of *Cyrtandra*. [W. C.]

**ISANTHUS.** A genus of labiates, having the calyx bell-shaped, with five equal lobes, enlarging as the fruit ripens; and the corolla slightly longer than the calyx, with five nearly equal lobes. The only species, *I. cæruleus*, is a small annual, covered with clammy hairs, the flowers minute, pale blue. It is a native of the southern parts of the United States, and is called False Pennyroyal. [G. D.]

**ISARIA.** An important genus of filamentous moulds, connecting them very closely with the lower club-shaped *Hymenomyces*. The genus is divisible into two distinct groups, in one of which all the species grow upon insects, and principally upon *Hymenoptera*. It is, however, suspected that all of these are mere conditions of different species of *Cordiceps*. The species of the second group grow upon various vegetable substances, and a few of these must be considered as mere sporiferous forms of other fungi. Some good species, however, remain, which are known by their threads being compacted with a solid mass, which may be either simple or branched, the free tips of which bear the spores. The limits between some of these and *Ptilularia* are so indefinite, that it is not always possible to say posi-

tively to which genus a species should be referred. [M. J. B.]

**ISARIEI.** A natural order of filamentous moulds containing those genera in which the fertile threads are compacted, and have deciduous pulverulent spores at their free apices. It must be observed, however, that the order contains two sets of species which are connected on the one hand with *Mucedines*, and on the other hand with *Dematiæ*, in which order the threads are more or less dark and carbonised. Little is known of exotic species. *Cerattum*, however, which, from its texture, would perhaps be better referred to *Hymenomyces*, occurs in Ceylon, and we have one of the darker series in India. North America, as might be expected, has some in common with Europe, besides an admixture of distinct forms. [M. J. B.]

**ISATIS.** A genus of *Cruciferae*, consisting of erect annual or biennial plants, natives of Southern Europe and Western Asia, one being found in China. They have undivided leaves, with a bluish bloom, the lower stalked, the upper clasping the stem; and the small yellow flowers are borne in long loose erect terminal panicles, and produce flat pendulous pods of an elliptical form, with a strong rib along each side.

*I. tinctoria*, the Dyer's Wood, is said to have been originally a native of South-eastern Europe, from whence it has spread by means of cultivation and become naturalised in most parts of Europe as far north as Sweden, and also in some parts of Asia. It is a biennial, growing from eighteen inches to three or four feet high, with a smooth straight stem, branched towards the top, the root-leaves stalked, inversely egg-shaped or oblong, and coarsely toothed, the upper ones narrow lance-shaped, with prominent auricles at the base. The pods are rather more than half an inch long, broad, and very blunt at the top, but tapering to the base.

Before the use of indigo became common among European dyers, the blue colouring matter called Wood, obtained from this plant, was an article of great importance, and the plant was extensively cultivated; but the introduction of indigo has almost entirely superseded it, and it is now only grown to a limited extent, and used chiefly by woollen dyers for mixing with indigo, in order to excite fermentation. It is generally prepared by grinding the leaves into a paste, which is then carefully fermented in heaps, and afterwards made into balls or bricks for sale. Small quantities of these balls are annually imported from the continent, amounting in 1859 to 200 cwt. The use of wood as a dye dates from very early times. Dioscorides, Pliny, and others, mention its use for dyeing wool; and Cæsar relates that the ancient Britons used it for staining their bodies—the word Britain being derived from the Celtic *brith* or *brû*, 'painted,' in reference to this custom.

*I. indigotica* is cultivated as a tinctorial

plant in the north of China, where it is called Tsin-ching. It is a small half-shrubby plant, with a decumbent stem, bearing at its extremity several long drooping racemes of small yellow flowers, and smooth black saddle-shaped pods about half an inch long. The lower leaves are rather fleshy, on long stalks, oval, lance-shaped, and pointed, with the edges slightly toothed, the upper ones very much

*Isatis indigotica.*

narrower and smaller. In the north of China, this plant takes the place of the indigo of the south, and its colouring matter is obtained by a process closely analogous to that employed in the preparation of indigo, but instead of being thoroughly inspissated, so as to form solid cakes, it is used by the Chinese dyers in a semi-liquid or pasty state. It is commonly employed for dyeing cotton cloth, to which it imparts a dark-blue colour. [A. S.]

**ISAUXIS.** A genus of Indian trees, belonging to the *Dipterocarpaceae*, and distinguished from *Vateria*, by the flowers being arranged in short axillary panicles, the segments of the calyx increasing in size as the fruit ripens, by the petals which are sickle-shaped and larger than the sepals; by the fifteen stamens, which have oblong anthers; and by the short style and club-shaped stigma. [M. T. M.]

**ISCHÆMUM.** A genus of grasses belonging to the tribe *Andropogoneae*, now included in *Andropogon*. [D. M.]

**ISCHARUM.** *Biarum*.

**ISCHNIA.** A genus of *Pedaliaceae*, containing a single species, a native of Mexico. It is an erect herb, with opposite petiolate ovate acute leaves, and pale violet flowers on long opposite and axillary peduncles, arranged in loose racemes. The calyx is five-toothed and persistent; the corolla tube slightly curved, and its spreading limb obscurely five-cleft. The nut-like fruit is indehiscent, and furnished with four long divaricate horns. This genus

has an herbaceous flower, but the fruit is that of *Pedaliaceae*.

**ISERTIA.** A genus of Central American shrubs or small trees, belonging to the *Cinchonaceae*. The flowers have a long tubular corolla, the limb of which is divided into six woolly segments; the anthers are six, sessile, concealed within the corolla; the ovary has six compartments, each containing several ovules. The species have handsome scarlet flowers. [M. T. M.]

**ISIDIUM.** A corolla-like elevation of the thallus of a lichen, bearing a globule at its end.

**ISKEEL.** *Scilla indica*.

**ISMENE.** A small genus of pancratiform *Amarylthidaceae*, consisting of bulbous plants of South America, mostly Peruvian. They have lanceolate leaves sheathing at the base, and tall scapes bearing at top an umbel of few or many flowers, the perianth of which has an elongated three-cornered tube curved in the upper part, and broader in the throat, a six-parted limb with narrow spreading segments, and a funnel-shaped six-lobed lacerately-toothed coronet, each lobe deeply emarginate and having an antheriferous filament projected inwards from the sinus. The ovary is three-celled with two ovules in each cell, and supporting a filiform declinate style with a globose stigma; and the seeds are few, green, and bulb-like. *I. Amancas* is the Peruvian Daffodil, and the name of Sea Daffodil is given to *I. calathina*, both very beautiful plants. [T. M.]

**ISNARDIA.** A genus of aquatic or marsh herbs belonging to the order *Onagraceae*, of which the characters are: stamens four; calyx four-parted persistent; capsule not tapering to a point; seeds many, destitute of any feathery or hairy appendage. *I. palustris* is remarkable only for having been found growing in the south of England about the middle of the seventeenth century, and for having been subsequently lost sight of until it was rediscovered in 1827. It is frequent in the continent of Europe, in North America, and the temperate parts of Asia. [C. A. J.]

**ISOBRIOUS, ISODYNAMOUS.** Growing with equal force; two of the names of the dicotyledonous embryo.

**ISOCARPHA.** A genus of tropical American plants of the composite family, nearly related to *Ageratum*, but differing in the achenes being destitute of pappus, and having interspersed among them on the conical receptacle numerous chaffy scales like those composing the involucre. They are branching weeds, with lance-shaped or linear leaves, and solitary or corymbose flower-heads. [A. A. B.]

**ISOCHILUS.** A few epiphytal orchids of tropical America, usually with slender erect stems, twelve to eighteen inches long furnished with broadly linear two-ranked leaves, and terminating in a very short bracted spike of small dingy

purple or white flowers. The relationship of the genus is with *Epidendrum*, but the lip is free, not connate with the column. The sepals and petals are free, nearly equal, and connivent; the column semiterete with two or three horns, and the anthers four-celled, with four pollen-masses, each with a recurved caudicle. [A. A. B.]

**ISOËTES.** A genus of *Lycopodiaceæ*, with subulate fronds, a globose rhizome, the apex of which is sunk, so that the bases of the older leaves are higher than those of the younger. The axillary capsules are incorporated with the base of the leaves, producing either antheridia in the shape of small oblong spores, or larger four-aided spores, which germinate by cell-division of the apex in which archegonia are formed, from whence ultimately the new plant is produced. Most of the species are strictly aquatic, but *I. Hystrix*,\* which has lately been found in the Channel Islands, grows in sandy places. The rhizome is often rough, with dark horny processes which are supposed to be abortive leaves, to which the name of phyllo-pods has been given. The leaves are studded with stomates, and the rhizome and roots contain annular vessels like those of *Equisetum*. The genus occurs in all the four quarters of the globe. [M. J. B.]

**ISOËTOSIS.** The generic name of an annual plant of the composite family found in South and West Australia. It gets this name from the great outward resemblance it bears to our common *Isolète*. It has numerous small sessile flower-heads, arising from the crown of the plant, and surrounded by a few grassy leaves, whence the specific name *graminifolia*. [A. A. B.]

**ISOGYRUS.** Forming a complete spire.

**ISOLEPIS.** A genus of cyperaceous plants, belonging to the tribe *Scirpeæ*. Distinguished by the inflorescence being in spikes, two or three together or solitary; scales imbricated on all sides, all floriferous, or more rarely the exterior scales empty; stamens three, rarely fewer; styles three. Steudel describes two hundred species, mostly natives of the warm temperate zones of both hemispheres. The British representatives are only two species, namely *I. setaceus*, and *I. Savii*, which with most British authors simply form a section of *Scirpus*. [D. M.]

**ISOLOMA.** *Lindæa*.

**ISOMERIS.** The name of a Californian shrub, forming a genus of *Capparidaceæ*. The flowers are yellow, with four equal sessile petals; stamens six, upon a fleshy receptacle which is prolonged into a narrow appendage; ovary stalked; capsule large, terminated by the short style. The plant has a disagreeable odour. [M. T. M.]

\* The sculpture of the small spores or antheridia is not, however, precisely the same, but more like that of *I. Duranti*, in the only specimen we have seen. It may possibly, therefore, be a species distinct from either.

**ISOMEROUS.** Equal in number; an isomerous flower is one all whose parts are equal to each other in number.

**ISONANDRA.** The inspissated milky juice of one of the species of this genus of *Sapotaceæ* constitutes the well-known Gutta Percha, and ten other species are known. They are all inhabitants of Southern India, Ceylon, Malaya, and the adjacent islands, forming lofty forest trees. The leaves are entire and leathery. The flowers small and inconspicuous, produced in little clusters, either in the angles of the leaves or at the ends of the young branches. They have a four or six-parted calyx and corolla enclosing double as many stamens, which are all fertile. The ovary has four or six cells, and eventually becomes a fleshy fruit containing one or two oily seeds.

*I. Gutta*, the species which yields Gutta Percha, is a large forest tree growing sixty or seventy feet high, with a trunk two or three feet in diameter. Its leaves are inversely egg-shaped and entire, of a pale green on the upper side, but covered beneath with short reddish-brown shining down. The flowers grow in clusters of three or more in the axils of the leaves.

The Gutta Percha (or Gutta Taban) tree, and its now famous product, was first brought into notice about twenty years ago by Dr. Montgomery at Singapore,

*Isonandra Gutta.*

where the tree was then common, but the Malays having adopted the extravagant method of felling the trees in order to obtain the milky juice, it is now quite extinct in that island, though it fortunately exists in Borneo, Sumatra, and other eastern islands. The average quantity yielded by each tree is 20 lbs.; and as 18,500 cwt. were imported into this country in 1859, it follows that 104,120 trees would have to be sacrificed for the supply of the English market alone. The raw Gutta Percha arrives in this country in lumps weighing from five to six pounds, which are cut into slices, softened in hot water, then torn into shreds by rapidly revolving cylinders set with sharp teeth, and thrown

into cold water, when the impurities sink and the Gutta Percha floats on the surface. The shreds are then transferred to hot water, and are made into solid masses which are afterwards kneaded by machinery, in order to expel the extraneous moisture.

One of the first uses to which Gutta Percha was applied in this country was for the soles of boots, its imperviousness to water and great durability recommending it for such purposes. From its property of becoming plastic by heat, it is valuable for modelling and moulding, and it is used for making a variety of useful articles, such as door-handles, pipes, plates, buckets, ear-trumpets, &c.; but its most important use is owing to its being a non-conductor of electricity, which, combined with its indestructibility in sea-water, renders it applicable for coating the wires employed for submarine telegraphs. Alkalies, vegetable acids, and weak mineral acids, also, do not act injuriously upon it, but strong sulphuric, nitric, and hydrochloric acids corrode it, and turpentine, benzole, chloroform, &c., completely dissolve it. [A. S.]

**ISONEMA.** A genus of dogbanes, having the corolla salver-shaped with a five-parted border, its tube without scales; the filaments of the anthers simple at the apex; and the base of the ovary without scales. *I. Smeathmanni* is the only species; it is a small hairy shrub, native of tropical Africa, with opposite leaves, and terminal clusters of flowers. [G. D.]

**ISOPAPPUS.** A genus of composite plants, found in Texas. The two known species are hirsute annual herbs, with numerous lance-shaped leaves, and an abundance of small yellow-rayed flower-heads, supported on slender stalks, and disposed in loose much-branched panicles. From *Stenotus*, and other allies, they differ in the narrow scales of the involucre, and in the pappus being composed of a single series of capillary nearly equal bristles: whence the name. [A. A. B.]

**ISOPHOROUS.** Transformable into something else. Thus, *Actinia* is an isophorous form of *Dendrobrum*, *Puzosia* of *Spathoglottis*, and, according to Morren, *Angulos* and *Lycaste* of *Mazillaria*.

**ISOPHYSIS.** A genus of *Melanthaceae*, also called *Heicardia*. It consists of a single Tasmanian species, *I. tasmanica*, with dry rigid, distichous, equitant, narrow, sword-shaped leaves, and purple flowers on bracteated scapes, taller than the leaves. The perianth is six-leaved, spreading in a star-like form, the segments acuminate; there are three stamens, with short broadly subulate filaments; and a pyramidal, bluntly three-cornered, three-celled, many-seeded ovary, with a short style, and three thick recurved stigmas. The spathe which terminate the scapes are one or two-flowered. [T. M.]

**ISOPLEXIS.** A genus of *Scrophulariaceae*,

consisting of two species, formerly included under *Digitalis*, but distinguished by Lindley on account of their shrubby habit, and their corolla, of which the upper lobes are reflexed. Both the *I. Sceptum*, from Madeira, and *I. canariensis*, from the Canary Islands, have been in cultivation in our greenhouses; they are handsome plants, with terminal racemes of showy yellow or orange-coloured flowers.

**ISOPOGON.** An extensive genus of *Proteaceae*, forming large shrubs or small trees, natives of the extra-tropical parts of Australia, principally in the south-west portions of it. The foliage is harsh and rigid, the leaves being of various forms, simple or much divided. They are filiform and sharp-pointed in *I. petrophiloides*, *I. teretifolius*, &c.; lanceolate and leathery in texture in *I. attenuatus*, *I. longifolius*, &c.; wedge-shaped and deeply toothed in *I. tripartitus*, *I. Baxteri*, &c.; and broadly ovate in *I. latifolius*. The flowers grow in globose, generally terminal heads, and have a regularly four-cleft calyx bearing on each of its concave segments a nearly sessile anther, a filiform style with a cylindrical or spindle-shaped stigma. The nut contains a single wingless seed. [L. H.]

**ISOPTERYX.** A genus of *Begoniaceae*, and the type of one of the sections of that order, according to Klotzsch. Its characters are: petals of staminate flowers, four, ciliate toothed at the apex; anther oval, short; filaments very long, not united; branches of the styles bipartitely multifid, and papillate, with slender somewhat terete lobes; fruit top-shaped, of a somewhat cartilaginous and papery consistence, three-horned above, attenuated at the base, shortly lengthened out at the apex. The horns are short cuspidate erect incurved. The one species referred hitherto is a native of New Grenada. [J. H. B.]

**ISOPYRUM.** A genus of *Ranunculaceae*, with the habit of *Thalictrum*, but really more nearly allied to *Helleborus*. They are natives of Europe and temperate Asia, and are slender herbs, with the leaves ternately divided, and with the leaflets again ternate or three-lobed. The flowers are stalked, without involucre, white, with five rather large petaloid sepals, and five or ten minute petals, tubular at the base, two-lipped; stamens ten or more; ovary of two to twenty carpels, which become follicles, containing several seeds each. *I. thalictrifolius* is not uncommon in central and southern Europe. [J. T. S.]

**ISOS.** In Greek compounds = equal. Placed before the name of an organ, it indicates that it is equal in number to that of some other which is understood: thus, *isostemonous* is said of plants the stamens of which are equal in number to the petals.

**ISOTOMA.** A genus of lobeliaceous herbs, distinguished principally by the salver-shaped corolla, the segments of which are spreading and nearly equal.

*I. longiflora*, a native of the West Indies, is a most venomous plant, producing dangerous cathartic symptoms. It proves fatal to horses that eat it. Others of the species are natives of Australia. [M. T. M.]

**ISOTROPIS.** The generic name of a few erect or decumbent leguminous herbs, found in South-west Australia. They mostly have slender rush-like stems six inches to a foot high, with alternate spatulate leaves about an inch long, usually bilobed at the apex; and solitary and long-stalked or racemed pea-flowers, the standard yellow with purple lines, and the keel and wings purple. The flowers are much like those of *Chorosema*, so often seen in greenhouses, and have a deeply four-cleft calyx, and orbicular bilobed standard, free stamens, and an oblong membranaceous pod. [A. A. B.]

**ISOTYPUS.** A genus of South American two-lipped composites. The present name supersedes *Caloseris*: which see.

**ISPRUK.** An Indian powder made from a species of *Delphinium*.

**ISTHIA.** One of the finest genera of *Diatomaceae*, distinguished by its trapezoid or rhomboid articulations, which are compressed and cellular, marked with a transverse zone, composed of smaller cells, and supported at one corner by a short stem. We have two native species which form most interesting objects for the microscope, and are very instructive as exhibiting, most distinctly, the peculiar mode in which cell-division takes place in these alga. The new frustules are either attached alternately as in *Diatoma*, or united to each other by means of a very short blunt stem, springing from one corner and fixed to different points of the older frustules. [M. J. B.]

**ITAKA WOOD.** A cabinet wood produced from *Macharium Schomburgkii*.

**ITEA virginica**, the only representative of this genus of *Escalloniaceae*, is a North American shrub, with clusters of white flowers, which open in summer. The calyx is bell-shaped; petals five, lance-shaped; stamens five, attached with the petals to the calyx; ovary with two compartments; fruit capsular, compressed. This shrub is frequently cultivated in shrubberies in this country, and derives its name from the Greek name for the willow, which it resembles in its mode of growth. [M. T. M.]

**ITOUBOU.** *Iontidium Ituba*.

**IYA.** The generic name of a few rank-growing annual or biennial weeds of the composite family, found in marshy or maritime places in North America. The stems have nettle or willow-like leaves, opposite below, and alternate above; and the greenish-white flower-heads, somewhat like those of *Artemisia*, are arranged in racemes, or placed singly in the axils of the upper leaves or bracts. The florets are all tubular, inconspicuous. [A. A. B.]

**IVETTE.** (Fr.) *Ajuga Chamapitys*. — **MUSQUÉE.** *Ajuga Rea*.

**IVLAIE.** (Fr.) *Lolium temulentum*.

**IVORY, VEGETABLE.** The hard albumen of the nuts of *Phytolophus macrocarpa*.

**IVY.** *Hedera Helix*. —, AMERICAN. *Ampelopsis hederacea*. —, GERMAN. A garden name for *Senecio mikanoides*. —, GROUND. *Nepeta Glechoma*. —, POISON. *Rhus Toxicodendron*.

**IVYWORTS.** Lindley's name for the *Araliaceae*.

**IXERBA.** A genus of *Breziaaceae*, represented by a single species, *I. brezioides*, which is an elegant evergreen tree of New Zealand, growing to the height of twenty feet, and having lance-shaped leaves, and terminal panicles of few large white flowers. The leaves are glossy, leathery, and toothed; and the flowers consist of five calyx leaves, five petals, five stamens, and a lobed disk surrounding a five-celled ovary. The name *Ixerba* is an anagram of *Brezia*. [A. A. B.]

**IXIA.** A genus of beautiful Cape Iridaceous bulb-tuberous plants, with narrow ensate leaves, and slender simple or slightly branched stems bearing spikes of large showy flowers, various in colour, and exceedingly attractive when fully expanded by sunshine. These flowers have a salver-shaped perianth, with a slender tube, and six-parted spreading equal limb, three stamens inserted in the throat, with filiform filaments and versatile anthers, and a three-celled ovary with numerous ovules, terminating in a filiform style, and three narrow linear conduplicate recurved stigmas. *I. striatiflora*, which has large sea-green flowers with black markings at the base of the segments, is a very singular-looking as well as beautiful plant. There are a great many species, and some garden varieties. [T. M.]

**IXIANTHES retzioides** is an erect South African shrub, with lanceolate whorled leaves, and very viscid flowers, growing singly or two or three together on axillary peduncles. It forms a genus of *Scrophulariaceae* of the tribe *Cheloneae*, distinguished by a two-lipped calyx, by the corolla which has a short broad tube, a short erect upper lip, and a longer three-lobed spreading lower lip, and by the stamens, of which two only bear anthers.

**IXIANTHUS.** A genus of the gentian family, represented by a perennial plant, native of Tenerife, with sticky leaves and yellow flowers. The calyx is provided with exterior triangular bracts; the corolla is wheel-shaped, with a four-cleft limb; there are four stamens; and the capsule is partly two-celled, two-valved. [M. T. M.]

**IXIOLENA.** A few annual Australian herbs compose this genus, which belongs to the same group of the composite family as the everlasting. They have glutinous smooth or woolly stems, six inches to 8

foot high, furnished with lance-shaped or linear leaves, and terminating in one or many white or yellow flower-heads about half an inch across. These contain numerous tubular and perfect florets, enclosed in an involucre of many narrow scales which are slightly bent out at the apex so as to resemble ray florets. From their allies they differ in the achenes being seated on a frilled receptacle, and crowned with a pappus of numerous long rough hairs, as well as in the nature of the involucre. [A. A. B.]

**IXIOLIRION.** The name of a few pretty bulbous amaryllidaceous plants of Asia Minor and Northern Asia. They have tunicated bulbs, and simple erect stems with

*Ixiolirion montana.*

leafy bracts, smaller upwards, and bearing a few flowers near the top. The leaves are narrow linear, channelled, glaucous, and sheathing at the base; and the flowers are erect long-stalked, blue or violet, with a six-parted funnel-shaped or subrotate perianth having narrow lanceolate divisions, six erect stamens, and a somewhat top-shaped ovary, with a filiform style and three narrow channelled stigmas. [T. M.]

**IXONANTHER.** A genus of the flax family, comprising five species which are found in the Malay peninsula and islands, and one in Hong Kong. They are smooth trees or bushes with obovate or elliptical leaves; and numerous small generally green flowers disposed in axillary forked corymbs usually longer than the leaves. The flowers have a calyx of five to six rounded sepals, a like number of rounded petals, ten to twenty long stamens, and an ovary which, when ripe, is a somewhat woody five-celled capsule. [A. A. B.]

**IXODIA.** A genus of *Compositæ*, comprising two erect glutinous herbs of Southeast Australia, with slightly-winged stems furnished with linear hyssop-like leaves, and numerous white flower-heads, disposed in corymbs at the ends of the twigs. They have much the appearance of *Achillea*, with this difference, that what gives the rayed appearance to the heads here is the

white tips of the involucreal scales, while in *milfolia* it is an outer row of strap-shaped florets. The achenes being destitute of pappus, each enveloped by a chaffy scale, distinguishes the genus from its near allies. [A. A. B.]

**IXORA.** A genus of Indian and tropical African shrubs, with corymbs of handsome flowers of a scarlet, pink, or white colour, and frequently having an agreeable fragrance. The corolla is salver-shaped with a long slender tube, into the throat of which the four or five anthers are inserted by means of very short filaments. The fruit is succulent, crowned by the calyx, containing two one-seeded stones.

Several of these fine Cinchonaceous shrubs are grown in stoves in this country. *I. coccinea* is used in India by the natives for various medicinal purposes. The name of the genus is supposed to be derived from the Hindoo deity, Iawarra, to whom the beautiful scarlet flowers of these plants are offered in the temples. [M. T. M.]

**JABOROSA.** A genus of South American herbs, belonging to the *Solanaceæ*, and differing from *Himeranthus*, principally in the funnel-shaped corolla, and the very short filaments of the stamens. [M. T. M.]

**JABUTI.** The edible fruit of *Psidium albidum*.

**JACARANDA.** A considerable genus of *Bignoniaceæ*, natives of tropical America, consisting of trees with opposite abruptly bipinnate leaves, the pinnae themselves imparipinnate. They have bluish flowers in terminal (rarely lateral) panicles. The calyx is five-toothed or five-parted; the corolla tubular at the base, dilated at the throat with an unequally five-lobed limb; there are four included didynamous stamens with a rudimentary fifth; and the capsule is roundish, compressed, two-celled, with many flattened winged seeds. Decandolle has divided the genus into two sections: *Monolobos*, characterised by having a single-celled anther and abruptly pinnate leaves; and *Dilobos*, with perfect two-celled anthers and imparipinnate leaves. Some species, especially *J. procera*, have the character of being useful in syphilitic affections. [W. C.]

**JACA, or JACK-TREE.** *Artocarpus integrifolia*.

**JACÉE.** (Fr.) *Lychnis dioica*. — **DES FRÉS.** *Centaurea Jacca*. — **DU MONTAGNE.** *Centaurea montana*.

**JACINTHE.** Another name for the Hyacinth.

**JACINTHE.** (Fr.) *Hyacinthus*. — **DE SIENNE.** *Muscari monstrosum*. — **DES JARDINIERS.** — *Scilla italica*. — **DU PÉROU.** *Scilla peruviana*. — **ÉTOILÉE.** *Scilla amara*. — **MONSTRUEUX.** *Muscari monstrosum*. — **MUSQUÉ.** *Muscari moschatum*. **PANICULÉE.** *Muscari monstrosum*. **PETITE.** *Hyacinthus non scriptus*.

**JACKAL'S KOST.** *Hydnora africana*.

**JACK-BY-THE-HEDGE.** *Sisymbrium*  
*Altharia*, or *Altharia officinalis*.

**JACK-IN-A-BOX.** *Hernandia sonora*.

**JACK-OF-THE-BUTTERY.** *Sedum acre*.

**JACQUIA.** The name of a tree of Southern India, forming a genus of *Cinchonaceae*. The flowers have an irregular calyx, divided into three segments; the corolla is funnel-shaped, with a slender tube and five-lobed limb; the anthers are sessile on the throat of the corolla; the style is very long, hairy in the middle; and the fruit is capsular, one-seeded, and surmounted by the three large sepals. [M. T. M.]

**JACKSONIA.** A genus of Australian undershrubs, belonging to that group of *Leguminosae* in which the ten stamens are free, and the pods two-seeded; and distinguished from *Daviesia* and other allies by the deeply and equally five-parted calyx, the absence of a carunculus or swollen excrescence to the seeds, and the want of stipules. Of upwards of thirty species a goodly proportion are leafless and have flattened stems which perform the functions of leaves; others have rush-like stems with juniper-like leaves; and some have the aspect of furze or broom bushes, with leaves like them, and branches often terminating in spiny points. The flowers are small and yellow. *J. scoparia*, the Dogwood of New South Wales, grows twelve or fifteen feet high, with a diameter of four to six inches, and furnishes a tolerably hard wood which takes a good polish, but is not applied to any particular purpose; when burning it emits an offensive smell, whence its local name. [A. A. B.]

**JACKWOOD.** A wood obtained from *Artocarpus integrifolia*.

**JACOBÉE.** (Fr.) *Senecio Jacobææ*.

**JACOBINIA.** A genus of *Acanthaceæ*, containing seven species, natives of Central America. They are erect shrubs with subcoriaceous leaves, and large flowers with a large herbaceous deeply five-cleft calyx, a ringent corolla with an erect oblong linear bidentate upper lip, and a three-cleft lower one, two stamens, a capitate two-lobed stigma, and a two-celled capsule. [W. C.]

**JACOB'S LADDER.** *Polemonium cæruleum*.

**JACQUEMONTIA.** A small genus of *Orobanchaceæ* of tropical America, with a single species from Asia. They are mostly twining herbs, sometimes woody at the base, with entire or slightly lobed leaves, and rather small flowers in axillary pedunculate cymes, the corolla usually broadly campanulate, and angular or broadly five-lobed. The ovary is two-celled with two ovules in each cell. This genus, separated from *Orobancha*, is intermediate between that genus and *Ipomœa* in the shape of the oblong two-lobed stigma. [W. C.]

**JACQUINIA.** A genus of handsome evergreen bushes, of the *Myrsine* family, peculiar to America, where they range from Florida to Brazil, and are usually found near the coast. They have alternate entire glossy leaves, and terminal racemes or umbels of vermilion flowers, having a five-parted calyx, a bell-shaped corolla with a flat border, five stamens with five alternating scales, and a one-celled ovary. The fruits are bright yellow, containing from one to three seeds imbedded in a mucilaginous placenta, which feature chiefly serves to distinguish the genus from *Clavija* and *Theophrasta*. *J. arnularia* is known to French settlers in the West Indies as Bracelet-wood, it being their custom to string its shining brown and yellow seeds into bracelets. The genus bears the name of N. I. de Jacquin, an eminent botanist, once professor at Leyden. [A. A. B.]

**JAGERY or JAGGERY.** A coarse kind of sugar made from the juice of the Coconut, and other palms.

**JAGONG.** The Malay name for Maize.

**JALAP.** A well-known drug, of which the best kind is obtained from *Exogonium Purga*, but other species are also collected under the same name. —, INDIAN. *Ipomœa Turpethum*. —, MALE. *Ipomœa batatoides*.

**JALAP-PLANT.** *Mirabilis Jalapa*.

**JALOUSIE.** (Fr.) *Dianthus barbatus*; also *Amaranthus tricolor*.

**JAMAICA-PEPPER.** One of the names given to Allspice.

**JAMALGHOTA.** The Hindoo name for Croton oil and seed.

**JAMBIRA.** A Sanscrit name for the Lemon, *Citrus Limonum*.

**JAMBOLAN-TREE.** *Calyptanthus Jambolana*.

**JAMBOLIER.** (Fr.) *Cyminoëma*.

**JAMBON DES JARDINIERS.** (Fr.) *Oenothera biennis*.

*Jambosa malaccensis*.

**JAMBOSA.** A group of myrtaceous

plants, belonging to *Eugenia*, from which it is sometimes separated on account of the throat of the calyx being drawn out beyond the ovary, and by the latter being many-celled. They are Indian trees, with large edible fruit, the most esteemed being the Malay Apple, *J. malaccensis*, and the Rose Apple, *J. vulgaris*, also called *Eugenia Jamboos*. [T. M.]

**JAMBOSIER.** (Fr.) *Eugenia* or *Jambosa*.

**JAMESIA.** A genus of *Hydrangeaceae*, from the vicinity of the Rocky Mountains, consisting of a shrub with opposite serrated leaves, and small few-flowered axillary and terminal cymes, the flowers small, with a downy bell-shaped five-cleft calyx, and five petals. [J. T. S.]

**JAMESTOWN-WEED.** An American name for *Datura*.

**JAMBOSADE.** The Rose Apple, *Eugenia Jambos* or *Jambosa vulgaris*.

**JAN.** (Fr.) *Ulex europæus*.

**JANAPA.** An Indian name for Sunn Hemp, *Crotalaria juncea*.

**JANCA-TREE.** *Amyris tozifera*.

**JANGL.** The Indian *Vallinaria alternifolia*.

**JANIPHA.** A name sometimes applied to a genus of euphorbiaceous plants, otherwise called *Manihot*. *Janipha Manihot*, and *Jatropha Manihot*, are other names for *Manihot utilisima*, the Mandioc plant, which yields cassava and tapioca.

**JANOO.** An Indian wood, *Lagerstræmia macrocarpa*.

**JANSONIA.** A genus of *Leguminosae*, peculiar to Western Australia, and represented by a single species, *J. formosa*, an erect branching bush of myrtle-like habit, with opposite smooth ovate-oblong leaves, and nodding heads of (apparently) scarlet pea-flowers, terminating the lateral twigs. The heads are surrounded by four ovate bracts, clothed externally with silky hairs. The plant agrees with *Brachysema*, in the great length of the keeled petal, compared with the very short standard which is here almost wanting, but it differs in the capitate inflorescence, and the great length of the lower lip of the calyx with respect to the upper. On account of the small standard the plant has also been named *Cryptosema*. [A. A. B.]

**JANTONG.** The Malay name for a Plantain leaf.

**JANUSIA.** A genus of Brazilian *Malpighiaceae*, mostly climbing shrubs, with flowers of two kinds (whence the name), as in *Gaudichaudia*, from which they differ principally in the fruit, consisting of three or fewer carpels, which have a dorsal wing thickened along one edge. [M. T. M.]

**JAPAN LACQUE.** A black hard varnish, obtained from *Rhus vernicifera*.

**JAQUIER.** (Fr.) *Artocarpus*.

**JARAT.** (Fr.) *Lathyrus Cicera*.

**JARBÃO.** *Stachytarpha jamaicensis*.

**JAREE.** An Indian name for the Jujube.

**JAROO.** *Lagerstræmia regina*.

**JAROSSE.** (Fr.) *Lathyrus Cicera*. — **D'AUVERGNE.** *Ervum monanthos*.

**JARRAH.** A durable West Australian wood, like mahogany, the produce of *Eucalyptus rostrata*.

**JASIONE.** A genus of dwarf herbaceous plants of the order *Campanulaceae*, bearing their flowers in terminal heads, with much of the habit of the compound flowers, and yet more of the scabious family. The most obvious character of the flowers is that the anthers are united by their bases so as to form a ring, and contain blue or purplish pollen. The species inhabit mountainous and sandy places in various parts of Europe and the north of Africa. *J. montana*, Sheep's Scabious, the only British species, bears numerous tufted root leaves, which are oblong, and hairy simple stems which are almost leafless, each surmounted by a head of bright blue flowers, all enclosed by a whorl of bracts. It is abundant in many heathy and moorland districts of Britain, and appears to have derived its name from its resemblance to a scabious, and from its abundance in sheep-walks. [O. A. J.]

**JASMIN.** (Fr.) *Jasminum officinale*. — **BLANC.** *Jasminum officinale*. — **D'AFRIQUE.** *Lyctum afrum*. — **D'AMÉRIQUE.** *Quamoclit coccinea*. — **D'ARABIE.** *Jasminum Sambac*. — **D'ESPAGNE.** *Jasminum grandiflorum*. — **D'ITALIE.** *Jasminum humile*. — **DE VIRGINIE.** *Bignonia radicans*. — **DU CAP.** *Gardenia florida*. — **JONQUILLE.** *Jasminum odoratissimum*. — **ODORANT DE LA CAROLINE.** *Gelsemium nitidum*. — **ROUGE DE L'INDE.** *Quamoclit coccinea*. — **TROMPETTE.** *Bignonia radicans*.

**JASMINACEÆ.** (*Jasminae*, *Bolivariceae*, *Jasminiverte*.) A natural order of corollifloral dicotyledons, belonging to Lindley's echin alliance of perigynous *Exogena*. Shrubs, often twining, with opposite or alternate, usually compound leaves; calyx and corolla regular, with five to eight divisions; stamens two, included within the salver-shaped corolla; ovary two-celled. Fruit a double berry or capsule; seeds with little or no albumen, and a straight embryo. Found chiefly in the tropical parts of India. The fragrant oil of *Jasmin* is procured from several species of *Jasminum*. There are half a dozen genera, and above 100 species. Examples: *Jasminum*, *Nyctanthes*. [J. H. B.]

**JASMINANTHES.** A genus of *Asclepiadaceae*, containing a single species from the Indian Archipelago. It is a twining shrub, with opposite oblong acuminate leaves, and yellowish flowers growing in few or many-flowered interpetiolar cymes.

The calyx is five-parted; the corolla is salver-shaped, with a long tube distended below, and a spreading five-cleft limb; and the staminal crown is wanting. [W. C.]

**JASMINE.** *Jasminum*. —, AMERICAN. *Quamoclit coccinea*. —, CAPE. *Gardenia florida*. —, CAROLINA. *Gelsemium nitidum*. —, GROUND. *Passerina Stelleri*. —, WHITE. *Jasminum officinale*. —, WILD, of Jamaica. A species of *Pavetta*.

**JASMINOIDE.** (Fr.) *Lyctium barbarum*.

**JASMINUM.** A considerable genus of *Jasminaceae*, dispersed over the warmer regions of the Old World, and containing one or two South American species. They are shrubs or climbers, with pinnate leaves or apparently simple, consisting of one leaflet—when the petiole is articulate. The white or yellow flowers are in axillary or terminal panicles, and have a tubular five or eight-cleft calyx, a cylindrical corolla tube and spreading limb, two included stamens, and a two-lobed ovary. Jasmynes are of little economic value, but they are prized as ornamental shrubs, on account of the fragrance of their flowers. The most universally cultivated is *J. officinale*, common throughout the centre and south of Europe, where it is thoroughly acclimated, though certainly not native.

Some species are used medicinally. The bitter leaves of *J. floribundum* have a very powerful action, and are employed in Abyssinia against the tape-worm. The bitter root of *J. angustifolium*, ground small, and mixed with the powdered root of *Acorus Calamus*, is considered in India as a valuable external application for ring-worm. The fragrant essential oil of *Jasmin* is obtained from *J. officinale* and *grandiflorum*; and an inferior oil is produced from the flowers of other species, as *J. Sambac*, &c. [W. C.]

**JASMINWORTS.** Lindley's name for the *Jasminaceae*.

**JASONIA.** A small genus of erect, branching, perennial, often glutinous composite herbs, confined to the Mediterranean region, nearly allied to *Pulicaria*, and technically distinguished from it by the nature of the pappus, which consists of a double series of rough hairs, the outer row like the inner but shorter, not crown-like as in *Pulicaria*. The stems have linear or lance-shaped leaves, and small yellow flower-heads, solitary at the ends of the twigs. [A. A. B.]

**JATAI.** A Brazilian name for *Hymenoc Courbaril*.

**JATAMANSI.** An Indian name for *Spike-nard*, *Eardastachys Jatamansi*.

**JATMI.** The common Indian name for *Jasminum grandiflorum*.

**JATROPHIZA.** This genus of *Ment-spermeaceae*, so called on account of the root of one of the species which is used in medicine, is closely allied to *Cocculus*, but the flowers have concave petals, enclosing the six stamens, which have thick filaments,

ending in a large fleshy connective, separating the lobes of the anthers, these opening by transverse slits. In the female flowers are three ovaries, densely hairy externally, and placed on a short stalk; and a three-parted stigma, with reflected segments. The fruit is clothed with long glandular hairs.

*J. palmata*, or *Cocculus palmatus*, furnishes the root known as Calumba-root, so called from a false impression that it was supplied from Ceylon. The plant is now

*Jatropha palmata*.

known to be indigenous in the forests of Mozambique, and the roots to be imported from thence. This drug is much esteemed as a bitter tonic, where a stimulant or astringent effect is not required; it is hence frequently employed in cases of indigestion, dependent upon languor and want of tone in the stomach, and attended by nausea and flatulence. It has likewise the effect of alleviating vomiting. [M. T. M.]

**JATIPATRI.** An Eastern name for Mace.

**JATIPHALI.** A Sanscrit name for the Nutmeg.

**JATROPHA.** A genus of *Euphorbiaceae*, consisting of woody plants, with alternate

*Jatropha podagrica*.

stipulate leaves, and flowers in cymes, the central flower female, and the outer ones male. The males have a calyx with

five divisions, five petals, and ten stamens, five long and five short, with the anthers united together around a central disk; the females have ten barren stamens, and a three-celled ovary.

*J. glauca*, an East Indian plant, known also under the name of *J. glandulifera*, furnishes an oil which is obtained by crushing the seeds, and which is used as an external application in rheumatism, &c. *J. podagrica* is a curious gouty-stemmed plant. See CURCUM, CHIDOSCULUS, MANIHOT. [M. T. M.]

JAU, JO. Indian names for Barley.

JAUBERTIA. An Arabian spiny shrub, with very small leaves, forming a genus of *Cinchonaceae*. The segments of the calyx and corolla are hairy, the latter organ is funnel-shaped, with the stamens inserted into its throat; the ovary has two one-seeded compartments; and the style is terminated by two spoon-shaped stigmatic divisions. [M. T. M.]

JAUNDICE BERRY. *Berberis vulgaris*.

JAURSA. An Afghan name for *Alhagi Maurorum*.

JAWA-WUT. A Javanese name for *Panicum miliaceum*.

JAWATRI. An Indian name for Mace.

JEANNARETTIA. A genus of *Pandanaceae*, figured in the *Voyage de la Bonite*, but not yet described.

JEANNETTE. (Fr.) *Narcissus poeticus*.

JEDWAR. *Curcuma Zedoaria*.

JEEAPOOTRA. An Indian name for the nuts of *Putranjiva Roxburghii*.

JEERA. An Indian name for Cumin.

JEFFERSONIA. A genus of *Berberidaceae* with the habit of *Sanguinaria*, a small glabrous perennial North American herb, with a horizontal rhizome, a simple naked one-flowered scape, and long-stalked root-leaves divided into two half-ovate leaflets. The flowers are large white, with four petaloid sepals, eight oblong flat narrow petals, and eight stamens. The capsule is pear-shaped and one-celled. *J. diphylla*, the only species, occurs from New York to the mountains of the Southern States; it is called Rheumatism-root in some places. [J. T. S.]

JELLY-PLANT of Australia. *Euchema speciosum*.

JENEQUEN. A Mexican name for the *Agave*, from the fibres of which cordage, sacks, &c., are made.

JENKINSIA. A genus of polypodiaceous ferns, allied to the *Acrostiches* through *Pachopteris*, of which it is by some regarded as an abnormal form. The sori form linear submarginal patches, with an areolate instead of universal attachment, which is the principal feature to separate them from the *Acrostiches*. The receptacle consists usually of the three outer series of

arcuate venules with three excurrent veinlets, and are hence compound, from which artificial characters it has been referred to the *Platyneris*, though having no natural affinity with *Platyneris* itself. The plant is a native of India, with much the general character of *Pachopteris*. [T. M.]

Also a genus of *Oleaceae*, now referred to *Miquelia*, consisting of climbing or twining shrubs, with alternate leaves, and dioecious five-petaled flowers collected into heads. The fruit is a drupe. There are two or three species, natives of tropical Asia. [J. H. B.]

JERCATCHREE. An Indian name for *Nux-vomica* seeds.

JERDONIA. A genus of *Cyrtandraceae*, containing a single species, a native of India, a small herbaceous stemless plant, with petiolate ovate leaves, and erect terminal scapes, terminating in a few-flowered umbel of funnel-shaped four-lobed flowers, with four stamens, all fertile, and an ovary surrounded at the base by a cup-shaped disk. [W. G.]

JERMAEE. An Indian name for *Cocculus indicus*.

JEROOGOO. *Caryota urens*.

JÉROSE. (Fr.) *Anastatica*.

JERSEY LIVELONG. *Gnaphalium luteo-album*.

JERUSALEM CROSS. *Lychnis chalcidonica*.

JERUSALEM STAR. *Tragopogon porrifolius*.

JESSAMINE. A popular corruption of Jasmine.

JESSENIA. A solitary palm, inhabiting moist woods in New Grenada, and attaining a height of sixty feet, with a trunk a foot in diameter, bearing a spreading crown of pinnate leaves, each of which measures twenty-four feet in length, and has numerous opposite leaflets, about four feet long by six inches broad, whitish underneath. The flower-spikes hang down from amongst the leaves, and are enclosed within two spathes, the outer one being a foot and a half, and the inner five feet long, bursting open along the back at the time of flowering. The flowers are arranged in threes (two males and one female) upon the lower, and in pairs (both males) upon the upper, part of the spikes. The fruit is about the size of a pigeon's egg, violet-coloured, having a thin, oily, eatable flesh, surrounding a fibrous husk which encloses a single bony seed. It is named *Jessenia polycarpa*, on account of the large number of fruits produced by a single flower-spike. [A. S.]

JETEE. An Indian name for *Moradania tenacissima*, whose fibres are made into bowstrings.

JETERUS. A yellowness of the green parts. Vegetable jaundice.

JETTITUD. An Indian name for *Liquorice* root.

**JEWBUSH.** *Pedilanthus tithymaloides*.

**JEWEL-WEED.** An American name for *Impatiens*.

**JEW'S-EAR.** The popular name of *Hir-nocle* (or *Eridia*) *Auricula Judæ*, a tough but gelatinous fungus, belonging to the natural order *Tremellini*. The plant is cup-shaped, velvety without and wrinkled within, and more or less rufous. It was formerly in reputation as an ingredient in gargles, but its virtues probably rest on no better foundation than a certain resemblance which the hymenium bears to the fauces. It is still to be met with in the shops of the herbalists. It grows principally on elder, but occasionally on elm. It is sometimes called the Jew's Ear *Peziza*, but the whole structure is totally different from that of that genus [M. J. B.]

**JEWUL, JINGUN.** Indian names for the gum-resin of the bark of *Odina Woder*.

**JIM CROW'S NOSE.** A West Indian name for *Phyllorhume*.

**JIPIJAPA.** A South American name for *Calandobea palmata*.

**JIQUILITE.** The native name for the Indigo plant in Central America.

**JIRA.** The Indian name for Cumini.

**JITO.** A Brazilian purgative, supposed to be a species of *Guarea*.

**JOAN SILVER PIN** *Pageter somniferum*

**JOAR, JOWAHREE, JONDIA.** Indian names for *Sorpha uluque*.

**JOBS TEARS.** *Cotiz Lachryma*.

**JOCASTE.** A genus of *Liliaceæ* from India, founded on *Smilacina purpuræa*. It has a horizontal rhizome, a simple leafy stem, scattered leaves, and a terminal raceme of violet-purple flowers, with the perianth leaves elliptical united at the base, six stamens with awl-shaped filaments, and a three-celled ovary. [J. T. S.]

**JOE-PYE WEED.** An American name for *Eupatorium purpureum*.

**JOHANNIS-BROD.** A German name for the pod of the Carob tree.

**JOHNSONIA.** A genus of *Liliaceæ*, allied to *Aphyllanthes*, founded on a South Australian plant, with fibrous roots, two-ranked linear leaves, and a simple scape terminating in an oblong nodding spike, with imbricated colored bracts, the lower ones small and sterile, the rest one-flowered. The flowers are small sessile, with a six-parted connivent perianth, three stamens, and a membranous capsule. [J. T. S.]

**JOINTED.** Falling in pieces at the joints, or separating readily there, or furnished with a distinct joint. Also applied to bodies having the appearance of being jointed, as the stem and leaves of *Juncus articulatus*.

**JOINTWEED.** An American name for *Polygonum articulatum*.

**JOLI-BOIS.** (Fr.) *Daphne Mezereum*.

**JONC.** (Fr.) *Juncus*. — À BALAIS. *Phragmites communis*. — DES CHAÎNIERS. *Scirpus lacustris*. — DES JARDINIERS. *Juncus glaucus*. — DES TONNELIERS. *Scirpus lacustris*. — D'INDE. *Calamus*. — ITALI. *Juncus effusus*. — FLEURI. *Butomus umbellatus*. — MARIN. *Ulex europæus*. — ODORANT. *Andropogon Schœnanthus*.

**JONCINELLE.** (Fr.) *Eriocaulon*.

**JONCIOLE.** (Fr.) *Aphyllanthes*.

**JONESTIA.** The generic name of a few trees of the leguminous family, also known as *baraca*, found in the Malayan peninsula and the adjacent islands. They are large shrubs or trees of twenty to forty feet in height, with the habit and leaves of *Brownea*, to which they are nearly allied, but they differ from them and others in the flowers being destitute of petals. The glossy leaves, a foot or more long, are made up of three to six pairs of oblong or lance-shaped leaflets, and the bright scarlet flowers are in terminal rounded clusters, having much superficial resemblance to those of the scarlet *Lorax*. Each flower consists of a tubular calyx supported by two rounded bracts, and having a four-parted petal-like border, and six to eight long protruding stamens. The ripe pod is emitter-shaped. The *Ushoka* of the Bengalese, *J. Asoca*, is very commonly planted throughout India, and is also cultivated in the Mauritius for the beauty of its flowers and foliage. Some Japanese species have flower clusters six to eight inches across. The genus bears the name of Sir William Jones, the eminent lawyer and scholar. [A. A. B.]

**JONNA.** An Indian name for grain.

**JONQUIL.** *Narcissus Jonquilla*. —, **QUEENANNE'S.** *Narcissus pseudonellus*

**JONQUILLE.** (Fr.) *Narcissus Jonquilla*.

**JORDANIA.** A genus of *Caruophyllaceæ*, consisting of herbs from Asia Minor, with the habit of *Queria*, or of the aggregate-flowered *Aronia*. The leaves are setaceous, united at the base; the flowers small, in dense cymes, with squarrose bracts, a tubular calyx of five united sepals with two bracts at the base, five petals, two styles, and four-valved capsules. [J. T. S.]

**JOSEPHIA lanceolata**, and *latifolia*, are the names given to two epiphytal vandaceous orchids of Malabar and Ceylon. They are stemless herbs, with a tuft of stalked, lance-shaped, coriaceous leaves, four to six inches in length, and slender scapes bearing panicles of minute flowers of a whitish colour, tinged with pink. The flowers are said to be renewed annually on the old scapes. The anther has four parallel club-shaped pollen-masses, attached to a dilated shield-like gland. Named after Dr. Joseph D. Hooker, a well-known English botanist. [A. A. B.]

**JOSEPHINIA.** A genus of *Pedaliaceæ*,

containing a single species from New Holland and the East Indian Archipelago. It is an erect or diffuse herb, with sub-opposite petiolate elliptical or lanceolate leaves, and reddish, shortly-stalked, solitary, axillary flowers. The calyx is unequally five-parted and persistent; the corolla has a short tube, a large campanulate throat, and a spreading five-lobed limb; there are four didynamous stamens, with a rudimentary fifth; and the nut-like four to eight-celled fruit is covered with numerous simple spines. [W. C.]

**JOSEPH'S COAT.** An American name for *Anaranthus tricolor*.

**JOSEPH'S-FLOWER.** *Tragopogon pratinensis*.

**JOTTE.** (Fr.) *Snaps arvensis*.

**JOUBARBE.** (Fr.) *Sempervivum*.  
**DES TOITS.** *Sempervivum tectorum*.

**JOUTAY.** *Outea guianensis*.

**JOVELLANA.** *Calceolaria*.

**JOVE'S-BEARD.** *Hydnum Barba Jovis*; also *Anthyllus Barba Jovis*.

**JOVE'S-FRUIT.** *Lindera melissæfolia*.

**JOWAR, JOAR.** Indian names for *Sorghum vulgare*.

**JUANULLOA.** A Peruvian shrub, with pendulous racemes of red flowers, constituting a genus of *Atropaceæ* (*Solanaceæ*), and distinguished by its distended coloured calyx, and its tubular corolla contracted at the throat, concealing the five stamens. The fruit is succulent, many-seeded, enclosed within the inflated calyx. *J. parastica* is in cultivation. [M. T. M.]

**JUBA.** A loose panicle, such as is often found in grasses.

**JURÉA.** The Coqui Palm of Chili, *J. spectabilis*, is the sole species of this genus of palms. It is very abundant in central Chili, between the latitudes of 33° and 35°, and is one of the most southern of American palms, existing only in a cultivated state in warmer latitudes. It has a tall straight trunk, bearing a crown of large pinnate leaves, and branching spikes of dark yellow distinct male and female flowers, enclosed in a double spathe. The fruit is roundish or egg-shaped, and has a thick fibrous husk, enclosing a hard one-seeded nut which has three small holes or pores at the bottom.

In Chili, a sweet syrup, called Miel de Palma, or Palm-honey, is prepared by boiling the sap of this tree to the consistency of treacle, and it forms a considerable article of trade, being much esteemed for domestic use as sugar. The sap is obtained by the very wasteful method of felling the trees, and cutting off the crown of leaves, when it immediately begins to flow, and continues for several months until the tree is exhausted, providing a thin slice is shaved off the top every morning, each tree yielding about ninety gallons. The nuts are used by the Chilian confectioners

in the preparation of sweetmeats, and by the boys as marbles. A quantity of them were brought to this country a few years ago, and sold under the name of Little Coker-nuts; they had a pleasant nutty taste. The leaves are used for thatching, and the trunks, being soft inside, and extremely hard towards the outside, are hollowed out, and converted into water-pipes, &c. [A. S.]

**JUBELINA.** A genus of *Malpighiaceæ*, consisting of three climbing shrubs of Guiana and Nicaragua. The flowers have a glandular calyx, ten stamens all fertile, and partly united ovaries. The dorsal wing of the fruit hardly exceeds the lateral ones in size. [M. T. M.]

**JUDAS-TREE.** *Cercis*.

**JUDIEGA.** Inferior Spanish olives, used for making oil.

**JUEPHUL.** An Indian name for the Nutmeg.

**JUGA.** The ridges on the fruit of umbellifers.

**JUGEOLINE.** (Fr.) *Sesamum brasiliense*.

**JUGLANDACEÆ.** (*Juglands*.) An order of monocotyledonous dicotyledonous plants, belonging to Lindley's quernal alliance of diclinous Exogens. Trees with alternate pinnate stipulate leaves, and unisexual flowers. Male flowers in catkins; perianth two to three or six-parted, with a scaly bract; stamens three or more. Female flowers in terminal clusters, or in loose racemes, with distinct or united bracts; perianth adherent, three to five-parted; ovary two to four-celled at the base, one-celled at the apex; ovule solitary, orthotropical; styles one or two. Fruit drupaceous, with a stony and often two-valved endocarp; seed exalbuminous, two to four-lobed at the base. Chiefly natives of North America. *Juglans regia* is the common walnut. *Carya alba* yields the American hickory nut. There are five genera, and about thirty species. [J. H. B.]

**JUGLANS.** The typical genus of *Juglandaceæ*, composed of the Common Walnut, and two or three other species, all of which form noble trees, and are natives of the temperate regions of Asia and North America. They have deciduous pinnate leaves, and bear flowers of separate sexes upon the same tree, and appearing in early spring before the leaves. The male flowers have a calyx of five or six scales, surrounding from eighteen to thirty-six stamens; whilst the calyx of the females closely envelopes the ovary, which bears two or three fleshy stigmas. The fruit has a fleshy husk, which does not split into regular divisions when ripe, but bursts irregularly, allowing the escape of the hard-shelled two-valved nut.

*J. regia*, the common Walnut tree, serves various useful purposes. The wood, particularly that of old trees, is valued by cabinet-makers on account of its beautiful velvety and dark colour; and in conse-

quence of its strength, lightness, and elasticity, it is extensively employed for gun-stocks. In Circassia, sugar is made from the sap, in the same way that the Canadians prepare that from the sugar-maple. The leaves are used medicinally in domestic practice; and an infusion of them is recommended as a vehicle for the administration of cod-liver-oil, in order to overcome its nauseous taste. The husk of the fruit yields a dark-brown dye; and the seeds a fine oil, which is suitable either for salad oil, or as a drying oil for painters. [A. S.]

It was said that in the golden age, when men lived upon acorns, the gods lived upon Walnuts, and hence the name of *Juglans*, *Jovis glans*, or Jupiter's nuts. The Romans called the walnut *Nux persica*, *Nux regia*, *Nux eubœa*, *Jovis glans*, *Dijuglans*, *Juglans*. Greek authors mention it under the names of *Carya*, *Carya persica*, and *Carya basiliæ*, or Royal Nut. We are not aware that the common English name of Walnut has been satisfactorily explained. On the contrary, we think an erroneous derivation has been given. Walnut, they say, is from Gaul-nut, presuming at the same time that the tree had been introduced from France into this country. But our ancestors, in their ordinary language, and that of the common people, did not use the classic name of Gaul in their designations of the things introduced from France in comparatively modern times. Walnut is doubtless of German derivation. In that language we find it is sometimes written *Walnuss*, sometimes *Wälschenuss*; the latter appears to have been the original. *Wälsch* simply means foreign; hence, *Wälschenuss*, a foreign nut, properly applied to the walnut, as regarded Germany, as well as the rest of the continent of Europe. In Dutch it is called *Wal-noot*, and its English, Danish, and Swedish names are modifications of this and of the original German term.

According to Dr. Royle (*Illustrations of the Botany, &c. of the Himalayan Mountains*), *J. regia* extends from Greece and Asia Minor, over Lebanon and Persia, probably all along the Hindoo Koosh to the Himalayas. It is abundant in Kashmir, and is found in Sirmore, Kumaon, and Nepal. The walnuts imported into the plains of India are chiefly from Kashmir. Dr. Hooker states that in the Sikkim Himalaya, the walnut inhabits the mountain slopes at 4,000 to 7,000 feet elevation. Professor Targioni says that it is a native of the mountains of Asia from the Caucasus almost to China. According to Pliny, it was introduced into Italy from Persia, and this must have been at an early date, for it is mentioned as existing in Italy by Varro, who was born B.C. 116. There is no certain account of the time it was brought into this country. Some say 1562, 300 years ago; but Gerard, writing only about thirty years later, mentions the walnut as being very common in the fields near common highways, and in orchards, and that being the case, its introduction in all probability had taken place at a much earlier period.

The nut, well known to every one, is covered with a green fleshy bark, which is very bitter, like the leaves. The tree grows to the height of forty or sixty feet, with a large spreading top, and thick massive stem. One accurately measured by Professor du Breuil, in Normandy, was upwards of twenty-three feet in circumference; and in some parts of France there are walnut trees 300 years old, with stems of much greater thickness. In the southern parts of England, the trees grow vigorously and bear abundantly, when not injured by late frosts in spring.

The timber of the walnut is light, a cubic foot, when dry, weighing about forty-seven pounds. Formerly, it was in much request for cabinet work, but since the introduction of mahogany it is less esteemed for that purpose. It is still, however, preferred to all other woods for gun-stocks, being light, yet tough and strong, and, with this desirable combination, it takes a good polish. The fruit is used for pickling in a green state, whilst the shell is still tender and can be easily pierced with a pin. The fruit becomes mature in the end of September, or in October; then, to bring it down, the trees are thrashed with poles, and many of the shoots are consequently broken; but an opinion has long been entertained, that this has the effect of making the trees more productive. It is, in fact, a rude mode of pruning.

Some varieties of the walnut are hard, and others tender-shelled. One of the latter is called the Titmouse Walnut (*Noyer mésange*), because the shell is so thin that birds, and especially the titmouse, can break it, and eat the kernel. Another variety, called the double walnut (*Noyer à biforc*), is large, of a square form, and when the shell is polished and hinged, it is fitted up so as to contain such presents as a pair of gloves, trinkets, &c. A variety called the Highflyer Walnut is considered the best English variety. In many parts, large quantities of oil are extracted from the fruit; indeed the walnut furnishes one-third of the oil made in France, and when well purified it is little inferior to olive oil; whilst, for some purposes in the arts, it is superior. Altogether, the Walnut is a tree of great importance—for its fruit as an edible product, for its oil, and for its timber. Trees of choice quality of wood have been sold for 600*l.* each. Its plantation, therefore, should not be neglected, but not too near dwellings, as some persons are affected by the powerful aroma of its foliage. [R. T.]

**JUGUM.** A pair of leaflets: thus, *uni-jugus* is one pair; *dijugus* two pairs, &c.

**JUJUBE.** *Elaeagnus vulgaris*, and *E. Jujuba*.

**JUJUBIER.** (Fr.) *Elaeagnus*.

**JULIANIA.** A genus consisting of two trees, one from Mexico, the other from Peru, which, as far as can be judged from the specimens known, appears to belong to the *Juglandaceæ*. The leaves are pin-

nate, the flowers dioecious; the males in short loose racemes very much like those of an oak; the females two or three together, imbedded in the summit of a broad flat peduncle having the appearance of a samara. The name of *Juliania* was also originally given by Llave to a Mexican shrub, which afterwards proved to be the *Chotaya* of Kunth.

**JULIENNE.** (Fr.) *Hesperia*. — **DE MAHON.** *Malcolmia maritima*. — **DES JARDINS.** *Hesperia matronalis*. — **JAUNE.** *Barbarea vulgaris*.

**JULLALYA.** An Indian name for hard wheat.

**JULOCROTON.** A genus of spurge-works, numbering about ten species, peculiar to tropical America, and ranging from Mexico to Buenos Ayres. They are branching undershrubs, having all their parts more or less clothed with white or rusty-coloured starry hairs, such as those seen in *Verbascum*. The alternate long-stalked leaves have ovate or heart-shaped blades; and the small green flowers are disposed in axillary or terminal bracted spikes, the lower flowers on which are fertile, the upper sterile. From *Croton* they differ in having irregular fertile flowers. [A. A. B.]

**JULUS.** The same as *Amentum*.

**JULY-FLOWER.** *Prosopis juliflora*. Also sometimes applied to the Stock Gilliflower.

**JUNCTURE.** A joint or articulation; the place where a body spontaneously separates into two parts.

**JUNCACEÆ.** (*Junci*, *Kingiaceæ*, *Xerotides*, *Bushes*.) A natural order of petaloid monocotyledonous plants, belonging to Lindley's juncal alliance of Endogens. Herbs with fasciculate or fibrous roots, hollow or flat and grooved leaves, and glumaceous (sometimes petaloid) flowers in clusters, cymes, or heads. Perianth dry, greenish or brownish, six-parted; stamens six or three, perigynous; anthers introrse; ovary one to three-celled; ovules one to three, or many in each cell; style one; stigmas often three. Fruit a three-valved loculicidal capsule, or indehiscent and one-seeded; seeds with a thin testa, which often becomes gelatinous when moistened. Natives chiefly of temperate or cold regions. The leaves are used for mats and the bottoms of chairs; the central cellular tissue for wicks of candles. There are upwards of 200 species distributed in about eighteen genera, of which *Juncus*, *Luzula*, and *Narthecium* are examples. [J. H. B.]

**JUNCAGINACEÆ.** (*Potamogetonaceæ*, *Arrow-grasses*.) A natural order of petaloid monocotyledonous plants, belonging to Lindley's alismal alliance of Endogens. Marsh plants, with narrow radical leaves, and hermaphrodite flowers in spikes or racemes. Perianth greenish; stamens six; anthers introrse; carpels three to six, united or distinct; ovules one or two, erect. Fruit dry, one to two-seeded; albumen none; embryo straight, with a late-

ral cleft. Natives of temperate or cold regions. *Triglochin* and *Apamegeton* are examples of the few genera. [J. H. B.]

**JUNCUS.** The Rush, a very extensive and almost universally distributed genus of *Juncaceæ*, with a peculiar rigid habit, and small greenish or brown flowers, arranged in heads or panicles. The flowers have two bracts and a six-leaved perianth resembling in texture the glumes of *Cyperaceæ*; six (rarely three) stamens; and a three-celled capsule, with numerous seeds. The soft pith of the stems of several species is used to form candle-wicks, and the stems themselves are made into mats. These plants are generally found in bogs or wet places, especially in sandy soil, and the great majority of the species occur in the temperate and Arctic zones. Of these twenty are included in the British flora. Of those with the inflorescence apparently lateral from the lowest bract resembling a prolongation of the stem, and having many leaf-like barren stems, *J. acutus*, *effusus*, and *glauca* are examples; while of those with the inflorescence evidently terminal and without barren stems, *J. obtusiflorus*, *acutiflorus*, *diversiflorus*, and *squarrosus*, furnish illustrations. [J. T. S.]

**JUNE-BERRY.** An American name for *amelanchier*.

**JUNERA.** An Indian name for *Sorghum vulgare*.

**JUNGERMANNIACEÆ.** The principal division of the liverworts (*Hepaticæ*), distinguished by the solitary capsules which, for the most part, split into a definite number of valves, and are filled with a mass of spiral elaters and spores. A few have a horizontal frond without any distinct leaves, but the greater part have distinct leaves, which assume the most grotesque forms, and are often folded or furnished below with a curious lobe. The leaves are arranged on two separate planes, the upper edge either resting upon the hinder edge of the one which succeeds it, in which case they are called incubous, or placed beneath it, when they are styled succubous. The leaves are mostly two-ranked, and there are frequently stipules on the under-side of the stem. As in mosses, the base of the fruit is often surrounded with leaves of a different form from those on the stem, besides which there are one or more membranes immediately surrounding the peduncle. The elaters which accompany the spores are distinct spiral vessels, and the outer cells of the capsules often contain rings, while the walls of succeeding cells are studded with deep broad pits, like those in punctate tissue. The spores germinate like those of mosses, producing a mass of threads from which the plants grow. The archegonia, which are sometimes solitary, are produced upon the stems, and the young plant is developed exactly as in mosses.

This large group is divisible into two natural sections of very unequal size, the one of which contains those genera which

have a one or two-valved capsule, and in part of these it is threaded like a columella; the other comprises the multitudes of species in which the capsule opens with four equal valves. These again are divided into frondose and foliose sub-orders, while the foliose are arranged in two sets, according as the leaves are incubous or succubous. Very rarely the capsule opens irregularly as in *Psilophyllum Ralfsii*, and as rarely more than one capsule is developed within the same calyx, as in *Jungermannia emarginata*.

*Jungermanniaceae* are found in all parts of the world, and are quite as abundant in the south as in the northern hemisphere. None of them seem to be of any economical value. One or two incubous species are found in amber. [M. J. B.]

**JUNGERMANNIA.** Almost all the *Jungermanniaceae* were originally referred to this genus, which is now, however, restricted to such succubous species as have a free terminal perianth, plicato-angular above, and cleft. It is the only one of its peculiar group which has its maximum in Europe, neighbouring genera, which contain many of the finest species, resembling small ferns, occurring in New Zealand, where they incurate more perhaps than in any other country. [M. J. B.]

**JUNGIA.** A genus of erect or climbing perennial herbs, belonging to the *Nassuvieae*, a tribe of *Compositae*, and differing from its allies in the chaffy receptacle of the flower-heads, the uniserial feathery or rough pappus, and the simple-lobed leaves. The ten known species are all South American. They have stalked five or seven-lobed leaves, usually clothed underneath with dense white or rusty down, and the twigs terminate in panicles or cymes of small white flower-heads of numerous perfect two lipped florets. [A. A. B.]

**JUNGLE-BENDY.** *Tetrameles*.

**JUNGLE-NAIL.** *Acacia tomentosa*.

**JUNIPER.** *Juniperus*; also applied in Nova Scotia to the Hackmatack Tamarack, or American Larch, *Abies pendula*.

**JUNIPERUS.** A genus of dicotyledons belonging to the *Gymnospermae*, and placed in the order *Coniferae*. The characters of the genus are:—Male flowers in catkins; anthers four to seven, one-celled, inserted on the lower edge or the scales. Female flowers few, in a small catkin, erect; scales of the catkin imbricate, lower ones barren; ovules three, surrounded by a three-cleft baccate involucre. The species have subulate leaves; and the fruit is berry-like, although in reality a reduced fleshy cone. There are forty or fifty known species. *J. communis* is the common Juniper; *J. Sabina*, the Savin; *J. bermudiana*, Pencil Cedar; *J. virginiana*, Red Cedar. The Juniper is the badge of the Murrays. One of the species is shown at Plate II b. [J. H. B.]

**JUNO'S TEARS.** *Verbena officinalis*.

**JUPITER'S BEARD.** *Anthyllis Barba Jovis*; also *Sempervivum tectorum*.

**JURINEA.** A genus of perennial herbs belonging to the thistle group of the *Compositae*, numbering about forty species, found chiefly in south Europe and Asia Minor, extending north to Siberia and east to Persia. A goodly number are neat little stemless plants, with a rosette of pinnatifid or entire hoary leaves, lying close on the ground, and surrounding a sessile thistle-like flower-head, consisting of many purple florets. Others differ from these in having the flower-heads borne on long naked stalks; and a few are branching plants, with stem as well as root leaves, which are either pinnatifid with linear divisions, or oblong or lance-shaped; while the flowers are numerous, disposed in corymba. From *Serratula*, and other allies, this genus differs in the four-sided, somewhat top-shaped achenes being crowned with a pappus of unequal rough hairs, which arises from within the minute cup-shaped and elevated border, and falls off in one piece, thus having the appearance of a painter's brush. [A. A. B.]

**JURUMU.** A Brazilian variety of Squash.

**JUSQUIAME.** (Fr.) *Hyoscyamus niger*.

**JUSSIEA.** An extensive genus of *Onagraceae*, consisting of herbs or more rarely shrubs, growing in marshes or ponds throughout the tropics, a few species reaching to sub-tropical regions. They have alternate leaves, and axillary yellow or rarely white, sessile or very shortly stalked flowers, with a persistent four-parted (rarely five to six-parted) calyx tube, as many petals, and twice as many stamens. Some of the species are astringent, as *J. villosa* from India, and *J. Caparossa* and *abra* from Brazil, where also occurs *J. ilosa* which yields a yellow dye. *J. decurrens* reaches north to Virginia. [J. T. B.]

**JUSTICIA.** A genus of *Acanthaceae*, occurring in tropical and sub-tropical regions, chiefly in India and Southern Africa. They are herbs or shrubs with red flowers in terminal spikes, furnished with large acbraceous bracts, or opposite and solitary flowers with small subulate bracteoles. The small calyx consists of five sepals; the corolla has a long tube and is two-lipped, the upper lip being concave and entire or notched, and the lower three-lobed, convex, and veined or rugose in the centre; there are two stamens, and two ovules in each cell of the ovary; while the capsule is laterally compressed below the seed-bearing part. [W. C.]

**JUTE.** The fibre of *Corchorus capsularis* and *C. olitorius*.

**JUVANEE.** An Indian name for *Ptychotis Ajowan*.

**JUVIA.** The Brazil Nut, *Bertholletia excelsa*.

**JUWANSA.** The Camel's Thorn, *Alhagi Maurorum*.

**JUXTAPOSITION.** The manner in which organs are placed with respect to each other.

**JYNTEE.** An Indian name for *Scabania aegyptiaca*, from which gunpowder charcoal is made.

**KABONG.** A Malayan name for *Sapierus saccharifer*.

**KADI-KANE.** An Indian name for *Panicum mitaceum*.

**KADSURA.** A genus of dicotyledonous plants belonging to the *Schizandraceae*. They are climbing nucllaginous shrubs, with white or reddish unisexual flowers; sepals three; petals six to nine; stamens fifteen or more, the filaments distinct or united; ovaries numerous, the style lateral; carpels beaked, distinct, forming a globular capitulum. There are about half a dozen species, natives of tropical Asia. [J. H. B.]

**KADUA.** A genus of cinchonaceous undershrubs, natives of the Sandwich Islands. The flowers have a leathery salver-shaped corolla, with a long tube and a four-parted limb. The fruit is capsular and adherent below to the calyx which is sometimes fleshy, while at the upper part it is detached from it. [M. T. M.]

**KÆMPFERIA.** A genus of tropical East Indian herbs, included among the *Zingiberaceae*. The flowers have a tubular calyx; a corolla with a slender tube, narrow equal outer lobes of the limb, much larger inner ones, and a flat lip; the filament short, prolonged beyond the anther into a two-lobed crest; the style thread-like, with a cup-shaped stigma. The roots or stocks of some of these plants are purple on the exterior, white within, and have an aromatic fragrance. Those of *K. Galanga* are used medicinally in India, and also as a perfume; those of *K. rotunda* are used for similar purposes. The flowers are curious, appearing before the leaves, from a very short stem. [M. T. M.]

**KAGENECKIA.** A genus of the rose family, differing from most of the others in the unisexual flowers and winged seeds, and from its nearest allies in the calyx segments overlapping each other in the bud. Of three known species two are found in Chili, and one in the Andes of Peru. They are trees with alternate, often gummy, ovate or lance-shaped leaves, and white flowers, much like those of the hawthorn. *K. oblonga*, known in Chili as *Lyday*, furnishes a wood used for building purposes, while the leaves being very bitter are used by the inhabitants to cure intermittent fevers. [A. A. B.]

**KAHO.** An East Indian name for the Lettuce.

**KAIMALEE.** *Rottlera tinctoria*.

**KAJU GARU.** A fragrant Malayan wood obtained from *Gonystylus Miqueliana*.

**KAKATERRO.** The New Zealand *Dacrydium taxifolium*.

**KAKOON.** An Indian name for *Setaria italica*.

**KALADANA.** *Pharbitis Nil*.

**KALAF.** A medicated water obtained from the male catkins of *Salix aegyptiaca*.

**KALA KANGNEE.** An Indian name for *Setaria italica*.

**KALANCHOE.** A Crassulaceous genus of robust erect herbs or shrubs, containing about thirty species, having its headquarters in tropical Africa, but also represented at the Cape, in tropical Asia, and in Brazil. It is distinguished from *Dryophyllum* and *Cotyledon*, by the quadripartite rarely quadrifid calyx. The flowers are rather large, usually in many-flowered paniculate cymes, yellow, purple, or scarlet. The leaves are fleshy, opposite, sessile or petiolate, entire crenate or pinnatifid. [J. Br.]

**KALE.** *Brassicaceae oleraceae acephala*, an open leaved variety of Cabbage. — INDIAN *Calandrinia esculentum*. — SEA. *Crabwe maritima*.

**KALLYMENIA.** A genus of rose-spored *Algae*, belonging to the order *Cryptomonadea*, distinguished by its compound capsule, and its flat nearly sessile indefinite frond, composed internally of threads sometimes combined with cells, and externally of cells. *K. reniformis* occurs on our southern coasts at extreme low-water mark, but is more common on the Atlantic coasts of France, though it occurs as high as Orkney. At first it forms a roundish or kidney-shaped frond with a very short stem; this becomes proliferous and produces from the edge a crop of similar expansions, which, however, are frequently torn by the waves, and as they grow after the laceration the ultimate appearance is very different from that of younger plants. Occasionally the fronds assume a longer outline. The species of the genus are at present ill-defined, and consequently their geographical distribution is doubtful. One, for instance, at the Cape, which was considered identical with our own, is now held by Agardh to be distinct. [M. J. B.]

**KALNIA.** A genus of heathworts, characterised by the border of the corolla having on the upper surface cavities in which the stamens are partly concealed. The name was given by Linnaeus in honour of Peter Kalm, a Swedish professor. The species are evergreen shrubs, natives of North America. Like many others of the heathwort order, they are deservedly favourites. In some species the flowers are in clusters more or less dense; in *K. hirsuta* they are solitary; in *K. latifolia* they are large and showy; in *K. angustifolia* smaller. The regular form of the corolla between wheel-shaped and bell-shaped, the depressions or small pouches in which the stamens lie, and the delicacy of texture and colour, render these plants objects of interest. In size of the whole plant there is considerable range, and even in the same species according to locality. *K. glauca* and *K. hirsuta* are shrubs of a foot in height; *K. latifolia*, in the more northern parts of the

United States varies from four to eight feet, while farther south it attains from ten to twenty feet, and when in full flower the dense thickets which it forms render it a prominent object. The flowers of this last species yield a honey said to be deleterious, and its leaves and shoots are certainly so to cattle; *K. angustifolia*, probably for the same reason, has received the name "cambkill." The powdered leaves of some are used as a local remedy in some skin diseases. The hard wood of *K. latifolia* is used in the manufacture of various useful articles. The Canadian partridge is said to become poisonous as human food after feeding on *Kalmia* berries. [G. D.]

**KALOSANTHES.** *Roehea*.

**KALUMBA-ROOT.** *Jateorhiza palmata*.

**KAMALA.** A down which covers the capsules of *Rottlera tinctoria*, and is used for dyeing orange.

**KAMBOU.** A name in the Kurile Islands for the *Fucus saccharinus*.

**KAMMA.** A Russian name for birch oil.

**KANARI.** The oil-producing Java Almond, *Canarium commune*.

**KANDELIA.** A Malabar tree, constituting a genus of *Rhizophoraceæ*. The flowers are remarkable for their five petals, which are inserted into a fleshy rim lining the interior of the tube of the calyx; they are divided beyond the middle into two segments, each of which is again broken up into a number of hair-like divisions; stamens indefinite; fruit one-celled, with only one seed. The species, like others of the mangrove family, present the curious phenomenon of the seed germinating within the fruit. The bark of *K. Rheedii* is used medicinally in India. [M. T. M.]

**KANGAROO'S-FOOT PLANT.** *Anigozanthus Manglesii*.

**KANILIA.** A genus of *Rhizophoraceæ*, [better combined with *Bruguiera*], consisting of trees and shrubs, natives of tropical Asia, the calyx of whose flowers have a limb divided into eight segments, shorter than the tube; and the eight two-lobed convolute petals are inserted into a disk lining the throat of the calyx, into which are likewise inserted sixteen stamens. The ovary is two to three-celled. [M. T. M.]

**KANTEN.** *Fucus cartilagineus*.

**KAPAS.** An Eastern name for the Cotton plant.

**KAPITIA.** A resin obtained in Ceylon from *Croton lacciferum*.

**KAPOK.** An eastern name for the cottony down of *Bombax pentandrum*.

**KARBI.** An Indian name for *Sorghum vulgare*.

**KARELINIA.** A genus of *Compositæ*, represented by a single species, *K. caespita*, found in littoral places on the borders of the Caspian Sea, and in Siberia. It is a smooth

erect woody-stemmed herb, having oblong lanceolate entire leaves, and corymbs of cylindrical purple flower-heads terminating the twigs, each head containing numerous tubular florets, the outer ones with pistil only, and their achenes crowned with a single series of soft white hairs, while the inner ones are perfect and have many series of pappus hairs to their achenes, which are cylindrical—not one series of pappus hairs and flattened achenes as in *Coryza* to which this plant is most nearly related. The genus is named in honour of M. Karelin, a Russian botanist. [A. A. B.]

**KARISHUTUR.** An Afghan name for *Aihagi Maurorum*.

**KAROO-VAILUM.** An Indian name for the gum of *Acacia arabica*.

**KARWINSKIA.** A Mexican genus of the buckthorn family, containing two or three species which have much the aspect of *Rhamnus*, and chiefly differ from them in having two instead of one ovule in each cell of the ovary. *K. Humboldtiana*, the most common species, has the smooth leaves marked underneath with prominent parallel nerves, and the minute greenish flowers in clusters in their axils, succeeded by little black berries. [A. A. B.]

**KASSOU-KHAYE.** The Senegal name for *Khaya senegalensis*, African Mahogany.

**KASSAR.** An Arab name for the Sugar Cane.

**KASSU.** A kind of Catechu, prepared from *Arca Catechu*.

**KAT, or KHÂT.** *Catha edulis*.

**KATHERINE'S-FLOWER.** *Nigella damascena*.

**KATUMBAR.** A Malay name for Coriander.

**KAUKOOR.** *Cucumis utilisetinus*.

**KAULFUSSIA.** A very distinct genus of marattiaceous ferns, found in India and Java, with thick rhizomes and coarse ternate fronds, but most remarkable for the structure of the sori, which are dorsal, sessile globose crenate fleshy coriaceous concave hemispherical bodies, consisting of ten or twelve spore-cases arranged in a single concrete cyclose series, each spore-case bursting on the inner face by a vertical oblong or obovate cleft. The veins are compoundly anastomosing, with free included veinlets, and compital receptacles. On the under surface of the fronds are found curious cavities which are supposed to be secreting organs. [T. M.]

**KAVA, KAWA.** Other names for *Ara, Macropiper methysticum*.

**KAVAROO.** The Tamil name for *Eleusine coracana*.

**KAWRIE TREE.** *Dammara australis*.

**KAYEA.** A genus of *Oliviaceæ*, differing from most others in its one-celled ovary, and from its nearest ally, *Calophyllum*, in

having four ovules instead of one. *K. Nordstranda*, found in Sihat, is a large handsome evergreen tree, with opposite narrow laurel-like leaves, and terminal panicles of numerous white flowers tinged with pink: each flower consisting of four calyx leaves, four petals, numerous stamens, and a simple style four-cleft at top. The fruits are rounded yellow drupes. *K. stylosa*, from Ceylon, is said to yield a useful timber, and to have very fragrant flowers. The genus bears the name of Dr. R. Kaye Greville of Edinburgh. [A. A. B.]

**KAYLA.** A Hindoo name for the Banana.

**KAYU-MANIS.** A Malay name for *Cinnamomum seylanicum*.

**KOCKS, KECKSIES, KIXES.** Country names for the dried fistulous stalks of cow parsley, hemlock, and various other wild umbellifers.

**KEDLOCK.** *Sinapis arvensis*.

**KEELED.** Formed in the manner of the keel of a boat: that is to say, with a sharp projecting ridge, arising from a flat or concave central plate, as the glumes of

**KEESLIP.** A Scotch name for *Galium*

**KEFERSTEINIA.** A small genus of epiphytal stemless bulbous orchids of New Grenada, with a few lance-shaped leaves, and from the lower axis solitary bracted peduncles, bearing a single flower at the apex. The sepals and petals are spreading, lance-shaped; the lip larger, fan-shaped, joined to the base of the column, which has a keeled crest, extending from the stigma halfway down in front; the anther has four unequal pollen-masses, attached to a strap-shaped caudicle as long as the gland to which it is fixed. [A. A. B.]

**KEITHIA.** A genus of the labiate order, having the calyx with five nearly equal teeth; the lower lip of the corolla with three nearly equal lobes; and the fruit dry and ovoid. The species are natives of Brazil. The genus was named after the Rev. F. Keith, a botanical author. [G. D.]

**KELINGOO.** An Indian name for *Datura edulis*.

**KELLETTIA.** A name given by Dr. in to *Prockia crucea*.

**KELP.** The ashes produced by burning sea-weeds, consisting principally of the common *Fuci* and *Laminariae*. They contain carbonate of soda and salts of potash, and were formerly used in the manufacture of coarse soap and glass, and returned a considerable revenue on rocky shores, or where large stones had been purposely placed to encourage the growth of seaweed. Modern improvements in chemistry, by which carbonate of soda was more profitably obtained from common salt, and the removal of the high duty from barilla, put an end to the manufacture, and the

benefit resulting in consequence to the public was unhappily in some measure counterbalanced by the ruin of many proprietors who had reaped a rich temporary harvest from what was supposed to be a permanent source of revenue. [M. J. B.]

**KEMPS.** *Plantago media*.

**KENDOO.** An Indian name for *Diospyros Melanoxylon*.

**KENGUEL.** The seeds of *Gundelia Tournefortii*, used as coffee in Asia Minor and Scinde.

**KENKERIG.** The Welsh name for a variety of *Parmelia saxatilis*, called *omphalodes*, which is much gathered for dyeing amongst the mountains. [M. J. B.]

**KENNEDYA.** A genus of prostrate or twining *Leguminosae*, peculiar to Australia, with the exception of *K. prostrata*, which grows also in Tasmania. They have wiry stems, with alternate, trifoliate, stipulate leaves, and axillary racemes of large handsome pea-flowers, bright red, pink, or almost black in colour. These have a two-lipped calyx; an obovate standard, the wings and keel nearly equalling it in length; ten stamens, one only of which is free; and an ovary tipped with a thread-like incurved style. They are distinguished from the allied *Hardenbergia* by their much larger and fewer flowers, which are never blue or white. *K. nigricans*, a Swan River species, is remarkable for its nearly black flowers. The genus is named in honour of Mr. Kennedy, once a nurseryman of Hammersmith. [A. A. B.]

**KENTIA.** A genus of palms, separated from *Areca*, chiefly on account of their ovary having only one cell, and their seed being solid and homogeneous, not having the nutmeg-like structure of the seed of true *Areca*, under which name, however, many botanists still retain them. They are natives of the islands of the Malayan Archipelago, Norfolk Island, and New Zealand; and have slender unarmed stems, marked with circular scars, supporting a cluster of large pinnate leaves, and branched flower-spikes, which bear numerous flowers of distinct sexes, each female being seated between two males.

*K. sapida* is the most southern known palm, being found in New Zealand as far south as lat. 38° 22', which is between two and three degrees further south than any representative of the order is found upon the Australian, African, or American continents. The New Zealanders call this palm Nikau, and use the young flower-spikes, just as they emerge from among the leaves, as an article of food. [A. S.]

**KENTROPHYLLUM.** A genus of *Compositae*, containing about a dozen species, distributed over the Mediterranean region, extending eastward to Kashmir, and west and south to the Canary Isles. They are mostly annual slightly branched thistle-like plants, with hard lance-shaped spiny-toothed leaves, and yellow, white, or pur-

ple flower-heads, each surrounded by a number of prickly scales, which are like the stem leaves. *K. lanatum*, one of the most widely distributed species, is remarkable for the loose white wool which hangs from the stems and flower-heads, giving them the appearance of distaffs loaded with wool. *K. arboreseens*, a Spanish plant, grows eight or ten feet high. According to Boissier, this plant gives quite a character to the lower warm regions in Granada, and is popularly known as *Cardo Santo*, or *Cardo lechero*. [A. A. B.]

**KERAMIDIUM.** The same as *Cystocarp*.

**KERMESINUS.** Carmine-coloured.

**KERNELWORT.** *Scrophularia nodosa*.

**KEROBETA.** An Abyssinian name for *Balsamodendron Myrrha*.

**KERRIA.** An evergreen shrub, with long slender branches, invested with smooth green bark, lanceolate acuminate leaves, which are coarsely and unequally serrated, and numerous buff-yellow flowers. The double-flowered form is commonly cultivated under the name of *Corchorus japonicus*. The structure of its flowers approaches that of *Spirea*, near which it is placed in the system. French: *Coréte du Japon*. [C. A. J.]

**KESHOOR.** A Bengal name for *Rottlera tinctoria*.

**KESTING, KESLING.** The Bullace Plum.

**KETCHUP, or CATSUP.** A name originally of Eastern origin, now applied to a favourite condiment prepared from various Fungi, as mushrooms, morels, champignons, &c. It is usually made by sprinkling the fungi when broken up with salt, and boiling the expressed juice with spice. The best way, however, is to let the juice drain without squeezing, and after standing for twelve hours to rack it off clear, and bottle it, filling the top of the bottle up with alcohol in which the proper spices have been previously steeped. Prepared in this way it retains its peculiar aroma much more perfectly than when boiled. Ketchup is often prepared for sale from agarics collected almost indiscriminately, no care being taken to discard notoriously poisonous species. The mass, moreover, frequently becomes putrid before it is boiled, and the ketchup is in consequence disgusting in flavour, and if taken largely very unwholesome. The best ketchup is prepared from *Agaricus campestris*, but a very good quality may be obtained from an admixture of other species, especially *A. procerus*, if care is used. [M. J. B.]

**KÉTIMONS DES INDIENS (Fr.)** *Cucumis sativus*.

**KETMIE. (Fr.)** *Hibiscus*. — **MUSQUÉE** *Abelmoschus moschatus*.

**KHAIR-TREE.** *Acacia Catechu*.

**KHÂT.** *Catha edulis*.

**KHAYA.** The name of a lofty Senegambian tree, forming a genus of *Cedrelaceæ* closely allied to *Swietenia*, but distinguished from it by the parts of the flower being in fours, and by the fruit bursting from above downwards. The bark of *K. senegalensis* is used as a febrifuge on the banks of the Gambia river, while the wood is like mahogany. [M. T. M.]

**KHEU.** *Melanorrhæa ustatissima*.

**KHISMIS.** A Malay name for Raisins.

**KHORMA.** A Malay name for the Date.

**KHUJJOOR.** *Phoenix sylvestris*.

**KHUS.** An Indian name for *Andropogon muricatus*.

**KHYAR.** An Egyptian name for *Cucumis sativus*.

**KIBARA.** A genus of but one species, *K. coriacea*, belonging to the *Moummeaceæ*, and differing from the other genera in the sterile flowers having but five to seven instead of many stamens. It is a large tree of Malacca and Java, having large opposite ovate oblong leaves, and small yellow flowers borne in axillary cymes. The fertile flowers, supported by two bracts, have the mouth of the calyx nearly closed by two or three series of scales enclosing a number of ovaries, which when ripe are oblong stalked drupes about half an inch in length. [A. A. B.]

**KIBI.** The Japanese name for Millet.

**KIDAR-PATRI.** An Indian name for *Limonium lauricola*.

**KIDNEY-BEAN TREE.** *Wistaria frutescens*.

**KIDNEY-SHAPED.** Resembling the figure of a kidney; that is to say, crescent-shaped, with the ends rounded, as the leaf of *Asium europæum*.

**KIDNEY-WORT.** *Umbilicus pendulinus*; also *Saxifraga stellaris*.

**KIELMEYERA.** A genus of resinous shrubs or small trees of Brazil, belonging to *Ternstroemiaceæ*, and related to *Camellia*, from which they differ in the petals being twisted instead of simply overlapping each other in the bud, and from others of their allies in their very numerous flattened and winged seeds. They have alternate, glossy, lance-shaped or elliptical leaves, with numerous nerves running at right angles to the midrib, and racemes or panicles of white or rose-coloured flowers, which in some species are small, but in others large and rose-like, thus suggesting the name *Roso do Campo*, by which some of the species are known in Brazil.

*K. speciosa*, called by the Brazilians *Malvo do Campo*, from the resemblance of its flowers to those of some mallows, has an abundance of mucilage in its leaves, which in decoctions are used by them for fomentations. M. St. Hilaire remarks as a curious circumstance, that we have soothing properties in the leaves of this plant,

while in those of the tea, to which it is related, we have stimulating properties. The Malvo do Campo is a tortuous tree eight to fifteen feet high, with short thick branches, corky bark, and elliptical leaves, the shoots terminating in a few rose-coloured flowers as large as camellias, with six curiously unequal-sided petals, and very numerous stamens. [A. A. B.]

KIERA. An Indian name for the seeds of *Amaranthus frumentaceus*.

KIGELIA *pinnata*, an African tree, found in Nubia, Abyssinia, Mozambique, to as far south as Natal on the eastern side, and in Senegal and Guinea on the western, is the only representative of this genus of *Crescentiaceæ*. It is of large size, with whitish bark and spreading branches, bearing opposite pinnate leaves, and long-stalked panicles of flowers, hanging down from the trunk or old branches: each flower being turned upwards, and having a two-lipped calyx with the lobes irregularly cut; a broad bell-shaped corolla divided at the mouth into five nearly equal lobes, enclosing two long and two short perfect stamens and five sterile ones; and a single-celled smooth ovary with a two-placed stigma. The fruit is often two or more feet long by from five to eight inches broad, hanging from a stalk several feet in length; it has a whitish corky rind, and is filled with pulp containing numerous roundish seeds. In Nubia this tree is held sacred; the negroes celebrate their religious festivals under it by moonlight, and poles made of its wood are erected as symbols of special veneration before the houses of their great chiefs. The fruits, cut in half and slightly roasted, are employed as an outward application in rheumatic and other complaints. [A. S.]

KIGELLARIA. A genus of *Flacourtiaceæ*, having for its chief distinguishing features a calyx of five distinct segments; the presence of scales at the base of the petals; and anthers opening at top by small round pores, instead of by longitudinal slits. The three known species are bushes or small trees of South Africa, with willow-like leaves clothed underneath with white starry down; in their axils grow the inconspicuous white unisexual flowers, the sterile ones in stalked cymes, and the fertile solitary, on different plants. [A. A. B.]

KING-CUPS, or KING'S CUP or COB. *Ranunculus bulbosus*, and the allied species.

KINGIA. A genus of *Juncaceæ* from South Australia, with the habit of *Xanthorrhæa* (grass tree), having an erect arborescent stem with crowded linear three-edged leaves at the top. The peduncles are shorter than the leaves; at first terminal and erect, but afterwards, as the stem elongates, lateral and reflexed, terminating in dense globose heads of flowers with a six-parted glumaceous perianth, six stamens, and a three-celled ovary becoming an indehiscent one-seeded pericarp. [J. T. S.]

KING-PLANT. *Anaclochilus setaceus*.

KING'S-SPEAR. *Asphodelus albus*.

KING'S TREE. The name among the Zulu Kaffirs of *Strychnos Atherstonii*.

KINGWOOD. A Brazilian wood believed to be derived from a species of *Triptoloma*; by some from *Brya Edenus*.

KINO. The name of various astringent gums. —, AFRICAN. The gum of *Pterocarpus erinaceus*. —, AMBOYNA. The gum of *Pterocarpus Marsupium*. —, BOTANY BAY. The inspissated juice of *Eucalyptus resinifera*. —, BUTEA or DHAK. The gum of *Butea frondosa*. —, INDIAN. The gum of *Pterocarpus Marsupium*.

KIPPER. *Orobis tuberosus*.

KIRIAGHUNA. *Gymnema lactiferum*.

KIRIATHA. A Malabar name for *Andrographis paniculata*.

KIRILOVIA. A genus of *Chenopodiaceæ* from Siberia, consisting of woolly annuals with a slender stem, membranous oblong or lanceolate entire leaves, and axillary sessile polygamous flowers in head-like spikes. The perianth has five (rarely four) small teeth; stamens five, with long exerted filaments; style two-cleft; fruit utricular, included in the unchanged woolly perigone. [J. T. S.]

KIRIS. (Fr.) *Matthiola greeca*.

KIRRITOCHEE. The fruit of *Terminalia angustifolia*.

KIRSCHENWASSER, KIRSCHWASSER. German names for a liqueur prepared from the cherry.

KISSENIA. *Fuscia*.

KISSMISS. A small kind of grape from which the Shiraz wine is made in Persia.

KISSING COMFITS. The candied roots of *Eryngium maritimum*.

KITAIBELIA. The name of a malvaceous plant peculiar to Hungary. The genus is distinguished by the outer calyx or involucre, which is cleft into seven or nine pieces; and by the numerous one-seeded carpels, which are aggregated together into a five-lobed head. *K. vitifolia* is a mallow-like plant, sometimes seen in English gardens; its leaves are employed in Hungary as a vulnerary. [M. T. M.]

KIT-JAP. The Japanese name of Ketchup.

KITTOOL, KITTUL. A Cinghese name for *Caryota urens*, also for its strong fibre.

KLAPA. A Malay name for the Coconut.

KLAPROTHIA. A genus of *Loasaceæ* readily distinguishable by having a four-toothed calyx and four petals to the flowers, instead of five which is the usual number, and by the sterile stamens having their apices dilated and fan-like. *K. mentzeloides*, the only known species, found in the Andes of Quito, is a twining annual herb,

with rough nettle-like leaves, and corymbs of inconspicuous white flowers terminating the twigs. Klaproth, whose name the genus bears, was a distinguished chemist of Berlin. [A. A. B.]

**KLEINHOFIA.** A genus of *Sterculiaceae*, consisting of a single species, *K. hospita*, a low branching tree with alternate heart-shaped leaves, and terminal panicles of small pink flowers, which are succeeded by top-shaped, bladder-like, five-winged fruits, with five cells having a single seed in each. These curious fruits are sufficient to distinguish the genus. The calyx is five-parted; the corolla consists of five narrow unequal petals; and the staminal tube bears on its apex five parcels of anthers, three in each parcel. The plant is a native of the Malay Archipelago, extending eastwards to the Solomon Isles. Its bruised leaves are said by Burmann to smell like violets. M. Kleinberg was once director of the botanic garden at Batavia. [A. A. B.]

**KLEINIA.** From the extensive genus *Senecio* a number of African species are severed by some authors who give to them the name of *Kleinia*, distinguishing them from true groundels more by habit than anything else. *K. verticillata* will serve to show what sort of plants they are. Growing on maritime rocks through all the Canary Islands, this plant is commonly known as Berode by the inhabitants; it is a fleshy-stemmed bush three to eight feet high, with thick candelabra-like branches, covered with scars of old leaves, and furnished at the apex with a rosette of pale-green lance-shaped leaves, somewhat like those of the oleander but fleshy in texture; and the numerous flower-heads are disposed in stalked corymbs arising from the axils of, and shorter than, the leaves. The achenes are ten-ribbed, surmounted by a white pappus of rough hairs. Most of the remaining species are South African; a few only Arabian; almost all having the stems (when present) fleshy, and leaves like those of that noted above. [A. A. B.]

**KLOPSTOCKIA.** A name sometimes given to the Wax Palm of the Andes and a few allied species, referred by others to *Ceroxylon*. [A. S.]

**KLOTZSCHIA.** A genus of umbellifers, having the fruit compressed from behind, each half with three dorsal approximate ribs but no oil-cells, and the lateral ribs small with single oil-cells. The genus was named in honour of Klotzsch, a well-known German botanist. The only species is an herb of the warmer parts of Brazil, having the stem leaves stalked, shield-shaped, five-lobed, and finely veined. [G. D.]

**KLUGIA.** A small genus of *Cyrtandraceae*, natives of India and Mexico. They are annual herbs with alternate leaves, and blue flowers in subsecund racemes. They have a five-cleft calyx; a two-lipped corolla, the upper lip being the smaller and bilobed, the lower entire; four included stamens, without trace of a fifth; and a

one-celled ovary surrounded by a disk, and crowned by a cup-shaped stigma. [W. O.]

**KNAPBOTTLE.** *Silene inflata*.

**KNAPWEED, or KNOFWEEED.** *Centaurea nigra*; also *C. Jacea* and *C. Scabiosa*.

**KNAURS.** Knobs or tumours formed on the stems or roots of plants; see *EXOSTOMA*.

**KNAUTIA.** A genus of herbaceous plants belonging to the *Dipsacaceae*, and allied to *Scabiosa*, from which it is distinguished by having its fruit invested with a toothed, not awned, calyx. *K. arvensis*, the only British species, is a common but graceful weed in cornfields; it grows to the height of two feet or more, with divided hairy leaves, and large handsome terminal lilac flowers, which are collected into convex heads, the outer florets much the largest, and having their outer segments larger than the inner, so as to assume the appearance of a ray, like that of the compound flowers. This is a favourite plant for showing the effect of burning tobacco on vegetable colour, for the flowers, immediately on being touched by a lighted cigar, assume a brilliant green hue. A similar effect may be produced by thus experimenting with other flowers of a reddish tinge, but none show so bright a green as this *Knutia*. [O. A. J.]

**KNAWEL.** *Scleranthus*.

**KNEE-JOINTED.** The same as *Geniculate*.

**KNEEPAN-SHAPED.** Broad, round, thick, convex on the lower surface, concave on the other; the same as *Meniscoid*, but thicker. See *PATELLIFORM*.

**KNEIFFIA.** A genus of hydroid *Fungi*, in which the hymenium consists of minute granules, surmounted by a little bristle-like point. It is very close to *Grandinia*. *K. setigera* is not uncommon in our woods on decayed sticks. [M. J. B.]

**KNEMA.** A genus of trees nearly allied to the nutmeg, and belonging to the *Myristicaceae*. The points of distinction lie in the three-lobed hairy calyx, and the stamens forming a column dilated at the top into a disk bearing the anthers at the margin. In the female flowers the stigma is provided with many teeth at its margin. The rigid leaves and the contracted inflorescence also form points of distinction. The trees are natives of India and other parts of tropical Asia. [M. T. M.]

**KNESBECKIA.** A genus of *Begoniaceae*. Its characters are: anthers obovate, truncate-tumid at the apex, with oblique chinks; filaments umbellately monadelphous; stigmas bipartite, dilated anteriorly at the base; placentas biflamellar, with the lamellae distinct, not united into a pedicel. There are thirteen species, found chiefly in Mexico and central America. The plants are more generally regarded as *Begonia*, as are all those proposed to be separated from it by Klotzsch. [J. H. B.]

**KNIGHTIA.** A genus of *Proteaceae*, containing a single species, *K. excelsa*, native of the northern island of New Zealand. It is distinguished by having a calyx of four sepals; four stamens with very long anthers and short filaments, one inserted on each sepal a little below the middle; and a long slender style thickened at the end. The fruit is a woody downy capsule, an inch in length with the long style still attached, containing four seeds, which are winged at the apex. The leaves are four to six inches long, very harsh, linear oblong, coarsely and rather bluntly toothed;

*Knightia excelsa.*

and the flowers grow in axillary racemes, nearly as long as the leaves, densely covered with a reddish-brown velvety down, as are also the flowers and their stalks. It forms a large tree about 100 feet high, erect and very narrow for its height, and consequently very conspicuous. The wood is much prized for its colour, which is a mottled red and brown; it is also useful as readily splitting for shingles. *Embothrium strobilatum*, a native of New Caledonia, has latterly been provisionally placed in this genus under the name of *K. integrifolia*, but the structure of the matured seeds has not been ascertained. [R. H.]

**KNIGHT'S SPURS.** *Delphinium*.

**KNIGHT'S STAR.** *Hippeastrum*.

**KNIGHTSWORT.** *Stratiotes aloides*.

**KNIPHOPIA.** *Triloma*.

**KNIPNÉE.** *Melicocca bijuga*.

**KNITBACK.** *Symphytum officinale*.

**KNOBTANG.** *Fucus nodosus*.

**KNOL KOHL.** *Brassica oleracea caulorapa*.

**KNOLLES.** *Brassica Rapa*.

**KNOFFERN.** A curious kind of gall, formed on some species of oak in Hungary and other parts of Europe.

**KNOTBERRY.** *Rubus Chamaemorus*.

**KNOTTHD.** Cylindrical, uneven on the surface, as the pod of *Onchodentum*.

**KNOTWORT.** *Polygonum aviculare*.

**KNOTWORTS.** Lindley's name for the *Flacobraceae*.

**KNOWLTONIA.** A genus of herbaceous plants of the *Ranunculaceae*, having, nevertheless, in outward aspect, much the appearance of umbellifers. The flowers have a green five-leaved calyx, several petals, and numerous stamens and carpels. The fruits are somewhat succulent, with a deciduous style, and are placed on a convex receptacle. These are acrid Cape plants, whose leaves are used to produce blisters. [M. T. M.]

**KNOXIA.** The name of a genus of cinchonaceous plants, consisting of Indian undershrubs, whose flowers have a four-parted calyx; and a salver-shaped corolla with lance-shaped segments, and a hairy throat, into which the stamens are attached. The fruit is a two-celled capsule, crowned by the calyx, and consisting of two halves, which separate from a slender central column. The species have pink or white flowers. [M. T. M.]

**KOARY.** An Indian grass used for making mats.

**KOBRESIA.** A genus of cyperaceous plants, belonging to the tribe *Caricinea*. Distinguished by the inflorescence being in spikes together, or what is termed aggregate; lower flowers female or pistilliferous, the upper ones male or staminate, without any perianth; perigone of one scale, enclosing the germen and covered by the glume. Steudel describes four species, which are natives of high mountains or northern latitudes. The British species, *K. caricina*, is a rare plant, which has hitherto only been observed to grow on the bleak moors of the north of England and Scotland. [D. M.]

**KOCHIA.** A genus of allied to *Chenopodium*, but with an urceolate perigone, the five segments of which at length send out from their beaks transverse membranous wings. They are herbs or undershrubs from the temperate to the old world, with sessile, linear, or cylindrical leaves (rarely absent), and axillary flowers. [J. T. S.]

**KODDA-PAIL.** *Pistia*.

**KODOYA BIKH.** *Aconitum ferox*.

**KODRO.** An Indian name for *Paspalum acrobiculatum*.

**KOELERIA.** A genus of grasses, belonging to the tribe *Poaceae*. It is distinguished by the inflorescences being crowded spike-like panicles; glumes unequal, two or three-ribbed; spikelets compressed, two to five-flowered; lower pale keeled, acuminate, or with a straight sub-terminal bristle; nut free. There are about three dozen species, which have a wide range, mostly inhabiting

climates. One of them, *K. cristata*, is a native of Britain, and is a beautiful grass, as it grows on dry sandy plains, or on dry hills. [D. M.]

**KOLREUTERIA.** A small-sized deciduous tree belonging to the *Sapindaceæ*. The generic characters are: calyx of five sepals; petals four with two scales at the base of each; stamens eight; ovary three-celled; capsule three-valved; seeds without an arillus. A native of China, first introduced into this country in 1793, and being handsome in regard to both leaf and flower, and hardy withal, it is much cultivated. The leaves are pinnate with an odd leaflet, the leaflets ovate coarsely toothed; the flowers yellow, disposed in terminal spreading clusters, and succeeded by large bladderly capsules which render the tree conspicuous till late in the autumn. [C. A. J.]

**KÖRNIGIA.** A genus of *Polygonaceæ*, consisting of an exceedingly small annual found in Iceland and Lapland, with alternate obovate, somewhat succulent leaves, short ochreate stipules, and terminal three-leaved flowers in small clusters with membranous bracts. [J. T. S.]

**KOHAUTIA.** A genus of cinchonaceous herbaceous plants, of no great beauty or interest. The corolla is salver-shaped with a long slender tube and pointed lobes; anthers sessile, within the corolla; capsule globular. [M. T. M.]

**KOHL.** A German name for Cabbage or Colewort. — **RABI.** *Brassica oleracea caulorapa*.

**KÖHLERIA.** A genus of handsome *Gesneraceæ*, represented by *K. hondenensis* and *K. Seemannii*. They have squamose stolons, upright stems with opposite leaves, and numerous axillary flowers having the corolla slightly deflexed, with a cylindrical somewhat tumid tube, and a narrow spreading limb; the stigma is bifid; and there are five nearly equal hypogynous glands. [T. M.]

**KOKOONA.** The Kokoon of the Cinghalese, a large forest tree growing sixty feet or upwards in height, in the central provinces of Ceylon, is *K. zeylanica*; it belongs to the natural order *Celastraceæ*, differing from the other genera of *Celastraceæ* in having a three-celled ovary, with four ovules in each cell, and exarillate seeds. The leaves are narrow at the base, but broad, rounded and with a small notch at the top, spotted beneath with numerous very small dark red dots. The fruit is three-sided and three-celled, each cell containing numerous seeds with broad wings. The Cinghalese use the yellow corky bark in the preparation of a kind of cephalic snuff, which they mix with ghee (vegetable butter) and introduce into the nostrils in order to relieve severe headache by encouraging a copious secretion from the nose. They also express an oil from the seeds and use it for burning in their lamps. [A. S.]

**KOKRA.** *Lepidostachys Roxburghii*, the hard wood of which is used for making musical instruments.

**KOLA.** *Cola* or *Sterculia acuminata*, and *tomentosa*.

**KOLBIA elegans** is the name given by Paillet de Beauvois to a plant which was formerly included in *Papayuceæ*, but is now considered to belong to the genus *Nodecca* in *Paspalaceæ*, and is referred by Dr. Masters to a form of *M. lobata*. It is imperfectly described, 'and the figure is apparently more fanciful than accurate, especially as to the colour of the flowers.' It differs from typical *M. lobata* in having cordate ovate leaves, and very long points to the anthers. Native of Upper and Lower Guinea. [J. Br.]

**KOLGAS.** *Colocasia antiquorum*.

**KOLKOUAL.** *Euphorbia alayanica*.

**KÖLLIKERIA.** A small genus of *Gesneraceæ*, separated from *Achimenes*. *K. argyrostigma* is a dwarf New Grenada heri with squamose stolons, rather large opposite leaves spotted with white, and racemes of small white flowers, mottled with red, the lower lip fimbriate. [T. M.]

**KOME.** A Japanese name for Rice.

**KÖNIGA.** The generic name sometimes given to the Sweet Alyssum, referred by Lindley to *GLYCE*: which see.

**KOOL.** The fruit of *Zizyphus Jujuba*.

**KOOLINGAN.** An Indian name for the Galanga root.

**KOOLLAH-i-HUZAREH.** The Cabul name of various species of *Statice*.

**KOOLTOO.** An Indian name for *Fagopyrum esculentum*.

**KOOMUGGI.** A Japanese name for wheat.

**KOONGOONIE.** An Indian name for *Setaria italica*.

**KOONGOO-TARO.** An Indian name for the flowers of a *Tamarix* used in dyeing.

**KOORINGA.** An Indian fibre obtained from *Tylophora asthmatica*.

**KOOROOMBA.** A name in Ceylon for the young Cocoa-nut.

**KOOSHA.** An Indian name for *Eragrostis cynosuroides*.

**KOOSUM, KOOSUMBA.** Indian names for Safflower; also for *Schleichera trygna*.

**KOOT.** The Indian *Costus* root.

**KOPEH.** The Tara, *Colocasia macrorhiza*.

**KOPSIA.** A genus belonging to the order of dogbanes, distinguished by having the corolla salver-shaped, its tube swollen above, the border of five spreading or reflexed lobes; the style ending in an oblong undivided hairy stigma; and the fruit of two drupes, one often abortive. The name was given in honour of Professor Kops, author of a botanical dictionary. The species are natives of Japan, usually

having milky juice, opposite leaves, and flowers resembling those of *Vinca*, and of handsome appearance. [G. D.]

**KORA KANG.** An Indian name for *Setaria italica*.

**KORARIMA, KURARIMA.** A large kind of Abyssinian *Cai damon*, the fruit of *Anomum angustifolium*.

**KORUMB.** An Egyptian name for Cabbage.

**KORRAS.** An Arabic name for Leek.

**KORTHALSIA.** A small genus of palms bearing a general resemblance to *Calamus*, having long flexible cane-like stems which climb up and become entangled among the branches of trees. Their pinnate leaves, also, terminate in long prickly tails like those of the *Culami*, and the lower part of their leaf-stalks forms a sheath round the stem; the leaflets being broad and shaped like a wedge or somewhat trapeziform, plaited, and irregularly toothed or torn at the top. The flower-spikes grow from the sides of the stem and have branches resembling catkins, bearing numerous flowers of separate sexes, the base of each branch being sheathed in an incomplete spathe. The males have a three-lobed calyx, a deeply three-parted corolla, and six stamens; the females a similar calyx, a tubular corolla trifid at the top, six sterile stamens, and a one-celled ovary. The fruit contains a solitary seed. There are five species, all natives of moist places in the forests of the Indian Archipelago. [A. S.]

**KOSHEL.** *Andropogon Nardus*.

**KOUBANKA.** A kind of wheat grown in Russia.

**KOUKOU.** A Tartar name for *Strychnos Ignati*, the *Ignatia amara* of authors.

**KOUKOUNARIA.** *Abies cephalonica*.

**KOUSSO, KOSSO.** An Abyssinian medicinal plant, *Brayera anthelmintica*; also called Cusso.

**KOYFUL.** An Indian name for wild Nutmegs.

**KRAMERIA.** An anomalous genus, nearly allied on the one hand to *Leguminosae*, and on the other to *Polygalaceae*, to which Bentham and Hooker refer it; it has even been separated as a distinct family, the *Krameriacae*. It consists of much-branched spreading undershrubs, indigenous to America, having alternate simple or trifoliate leaves, and flowers in racemes. The calyx consists of four or five irregular coloured sepals, and the corolla of four or five petals, the three inner of which are very small and anguiculate; the stamens are four or fewer, unequal, and open at the end by pores; the ovary is one-celled with two suspended ovules; and the one-seeded fruit is covered with hooked prickles. On careful examination the irregularity of the flower proves to be of the same kind as that of *Leguminosae*, one of the petals being superior or directly next the stem from which

the flower-stalk springs, on which account it appears undoubtedly preferable to refer it to *Leguminosae*. In *Polygalaceae* a sepal occupies that position, so that neither of the petals which are alternate with it can be directly superior. The sepals of *Krameria* are, however, sometimes partially displaced from crowding or inequality, so that one of them may appear superior.

*K. triandra*, remarkable for its entire obovate acuminate leaves, covered on both sides with silky hairs, is one of the species most known as yielding the Rhatany roots of commerce, but all the species, as far as known, are intensely astringent. In Peru an extract is made from this species which is a mild, easily assimilated, astringent medicine, possessed of great power in passive, bloody, or mucous discharges; it acts as a tonic in weakness of the digestive organs and muscular debility, and is even useful in intermittent and putrid fevers. It is also astringent, and restores tone to relaxed parts, and when applied in plasters is said to correct and cure all kinds of ulcers. An infusion is used as a gargle and wash, and the powder forms along with charcoal an excellent tooth-powder. The colour of the infusion of the roots of the *Krameria* is blood-red, on which account advantage is taken of it to adulterate port wine. [B. C.]

**KRAUSIA.** The name of a genus of *Cinchonacea*, consisting of a Natal shrub, whose flowers have a calyx with a short five-cleft limb, a funnel-shaped corolla with a short tube and a five-cleft limb; anthers placed on very short stalks on the hairy throat of the corolla; and an ovary crowned by a large fleshy disk, and a large spindle-shaped stigma which is divided into two lobes; fruit fleshy, two-celled, two-seeded. [M. T. M.]

**KRAUT.** A German name for Colewort or Cabbage.

**KREAT or GREAT.** A tonic infusion of the root of *Andropogon paniculata*.

**KREYSIGIA.** A genus of *Melanthaceae* from New Holland, with a roughish simple stem, ovate lanceolate amplexicaul leaves, smooth above and rough below, and axillary, solitary, one-flowered peduncles, with an involucre of three bracts below the middle. The flowers are pale lilac with a six-leaved spreading deciduous perianth, having glandular appendages, six stamens, and three stigmas. The capsule is somewhat fleshy. [J. T. S.]

**KRYNITZKIA.** A genus of *Boraginaceae* from New California, allied to *Echinopspermum*, but having the nuts quite smooth. They are hispid annuals with sessile leaves, and small flowers with a very hispid calyx, and a white salver-shaped corolla, having yellow scales in the throat. [J. T. S.]

**KUCHOO.** An Indian name for the tubers of *Colocasia antiquorum*, *Arun maculatum*, &c.

**KUCHOORA.** *Curcuma Zerumbet*.

**KUDUMBA.** *Net*

**KUMBA.** The Indian name for *Butea* King.

**KUMBUH.** An Indian name for the aromatic bark of *Myrica aspid.*

**KUMTIA.** A small genus of *Compositae*, differing from its allies in the many striate achenes, seated on a naked receptacle, and crowned with a single series of capillary and feathery pappus hairs. The species of *K.* is named by Torrey and Gray, *n. Bipartitum*, five-angled achenes. [A. A. B.]

**KUJGOR.** An Indian name for Dates.

**KUMBOO.** The Tamil name for spiked Millet, *Pennisetia spicata*.

**KUMERA.** A New Zealand name for *Bolobolus*.

**KUMKUMA.** An aromatic drug and perfume obtained from *Didymocarpus aromaticus*; also the Malay name for Saffron.

**KUMLA.** An Indian name for *Citrus Aurantium*.

**KUMMEL.** A German name for Cumin or Caraway seeds.

**KUMON.** An Indian name for Cumin.

**KUMNYAN.** The Malay name for Frank-

**KUMQUAT.** A variety of *Citrus japonica*.

**KUNDALOO.** A large kind of Indian Nettle.

**KUNDEL.** An Indian name for Sage-

**KUNBOO.** An Indian name for *Stachys* *flavida*.

**KUNKIRZED.** An Arabian name for the gum of *Oryza Scolyman*.

**KUTHIA.** A genus of palms, containing but one species, *K. montana*, a reedy palm, with a ringed stem about an inch in thickness, and twenty feet high or more, inhabiting the temperate mountain-regions of New Granada, where the natives call it *Cana de la Vibora*, i. e. Snake Cane, from the resemblance of its stem to a snake, and they consider its juice to be a remedy against the bite of that reptile. It has a terminal tuft of pinnate leaves, three or four feet long, beneath which the flower spikes, which are enclosed in several sheaths, and bear both male and female flowers, are produced. The fruit is about

the size of a clove, of a green colour, containing a single seed. Besides the use of its juice for curing snake bites, the Indians hollow out the reedy stems of this palm for the purpose of making blowpipes, through which they expel poisoned arrows to a considerable distance. [A. B.]

**KURREE.** An Indian name for the cut stalks and straw of the *Sorghum*, used as fodder for cattle.

**KURDEH, CURDEE.** Indian names for Safflower.

**KURPAH.** A kind of Indigo.

**KURRAJONG.** A native Australian name for several fibrous plants. — **BROWN.** *Commersonia platyphylla*. — **GREEN.** *Hibiscus heterophyllus*. — **TASMANIAN.** *Platanthus didotides*.

**KURTAU.** A Malay name for the Mulberry.

**KURUNDA.** An Indian name for *Cassia Aurantia*.

**KUSHMUT.** An Indian name for the root of *Costus speciosus*.

**KUSHNEEZ.** The Persian name for Coriander seed.

**KUTOHOORA.** An Indian name for the roots of *Curcuma*.

**KUTEERA, KUTERA.** A gum obtained from *Cochlospermum Gossypium*; also from *Sterculia urens*.

**KUTH.** An Indian name for *Acacia Catechu*.

**KUTHAR-CHARA.** An Indian name for *Limonia laurapa*.

**GA, KUKULEGA.** In the tonic seeds of *Cassia*.

**KUTKEY.** An Indian name for Helibore.

**KYABOOCA.** An ornamental wood obtained in the Eastern Archipelago, from the excrescences or burrs of *Pterospermum indicum*; the same as Amboyna wood.

**KYLLINGIA.** A genus of cyperaceous plants, belonging to the tribe *Cyperes*. distinguished principally by the inflorescence being in solitary heads, rarely two to three together; spikes compressed, one to two-flowered, the upper flowers male; stamens one to three; styles cleft. There are upwards of fifty species, the greater part natives of Brazil and South Africa, with a few from Australia. [D. M.]

ENCYCLOPAEDIA  
OR THE  
TREASURY OF BOTANY

PART II.

L to Z, with Supplement.

# THE TREASURY OF BOTANY.

## PART II.

**LABARIA PLANT** of Demerara. *Dracontium polyphyllum*.

**LABATIA.** A genus of tropical American trees, belonging to the *Eupotamoceae*. The flowers have a four-parted calyx, whose segments are arranged in two rows; five fertile stamens inserted at the base of the tube of the corolla, alternating with five scale-like abortive stamens placed on its throat; a four-celled ovary surmounted by a style that does not project beyond the corolla; and a fleshy fruit. [M. T. M.]

**LABEL, LABELLUM.** The third petal of an orchid, usually turned towards the lower front of the flower, and very different in form from the remainder. Also a similar petal in other flowers.

**LABIATÆ.** (*Lamiaceae, Labiatae*.) A natural order of Dicotyledonous plants, belonging to Lindley's Echio Alliance of perigynous Exogens. Herbs or under-shrubs with square stems, opposite and exstipulate leaves, and flowers in verticillasters. Calyx tubular, persistent, five to ten-toothed or bilabiate; corolla bilabiate; stamens four, didynamous, or by abortion two; anthers two-celled, or one-celled by abortion; ovary deeply four-lobed on a disk; style basilar; stigma blind. Fruit one to four achenes enclosed by the calyx; seeds erect with little or no albumen. Natives of temperate climates. Many of them are carnitative, and yield volatile oils. Mint, sage, lavender, rosemary, hyssop, patchouly, marjoram, horrhound, thyme, basil, savory, belong to the order. There are upwards of one hundred genera, and about 2,500 species. [J. H. B.]

**LABIATE.** A term applied to that form of a monopetalous calyx or corolla which is separated into two unequal divisions, the one anterior, and the other posterior, with respect to the axis.

**LABIATIFLOUS.** A term applied to composites whose corolla is labiate.

**LABICHERA.** A genus of *Leguminosae* of the suborder *Campalipiniæ*, allied to *Cassia*, but the sepals and petals are occasionally reduced to four, and the stamens are two only (with the anthers either both alike or one of them produced into a tube exceeding the other, and filled with pollen at the base only). There are five species, all Australian glabrous shrubs, with pinnate leaves consisting of one conspicuous terminal usually lanceolate and sharply pointed leaflet, and two or more small ones at its base. The flowers are yellow, in short axillary racemes, and rather showy.

**LABIOSE.** A polypetalous corolla having the appearance of being labiate.

**LABISIA petholus** is the name given by Lindley to the *Ardisia pumila*, a native of the Eastern Archipelago, which differs from the rest of the genus in the more induplicate aestivation of the corolla, in the almost apiculate inflorescence, and in the shape and venation of the leaves, which are almost those of some monocotyledonous plants, hence it was mistaken for a *Pothos* in the garden of the Horticultural Society until it flowered. For the same reason it was proposed by A. De Candolle as a section of *Ardisia* under the name of *Murantoides*.

**LABIUM.** The lower lip of a labiate corolla.

**LABIAB.** A genus of tropical pulse more usually included in *Dolichos*. The two recognised species are natives of India, but they have been so widely spread by cultivation that they are now found naturalised in most tropical countries. They are twining herbaceous plants, with trifoliate leaves, and long-stalked racemes of flowers, in which the two lower petals are bent inwards at a right angle, not twisted as in *Phaseolus*; and nine of the stamens are united. The pods are flat, marked along the edges with rough tubercles or warts. *L. vulgaris* and *L. cultratus* are greatly cultivated in tropical countries, the young pods taking the place of our kidney beans, while the seeds or pulse, on account of their nitrogenous qualities, afford nutritive and wholesome food. There are several varieties, some of which yield better-flavoured pulse than others. [A. B.]

**LABORDEA.** An evergreen shrub from the Sandwich Islands, described and figured by Gaudichaud as a genus of *Loganiaceae*, but of doubtful affinity.

**LABOUCHERIA.** A North Australian tree of the *Leguminosae Mimosæ*, scarcely sufficiently distinct from the African *Erythrophloeum*.

**LABURNUM.** *Cytisus Laburnum*. —, SCOTCH. *Cytisus alpinus*.

**LABYRINTHIFORM.** Marked by sinuous intricate lines: the same as *Dadaleus*.

**LAC.** A fluid having an opaque appearance, and either white, orange, or some such colour, occurring in many plants. Also the name of a gummy substance produced by *Ptychirina monosperma*, *Aleurites lucifera*, *Schleichera trifida*, &c.

**LACÆNA.** A genus of epiphytal orchids with the habit of *Acinetus*, and approaching very nearly to it in structure, but differing in having the lip articulated with the column as well as in the middle, and in having but two pollen-masses instead of four, these being attached to a long slender caudicle. *L. Schottii*, the original species, is a native of Guatemala. [T. M.]

**LACAUSADEA.** *Polybotrya*.

**LACHE-BARK.** The inner bark of *Lagetta Monticola*.

**LACEPDEA.** A Mexican shrub, described by Kunth as a distinct genus, but which has since proved to be a species of *Turpinia*.

**LACE-LEAF PLANT.** *Ouvirandra*.

**LACERATE, LACERUS.** Irregularly divided by deep incisions.

**LACHENALIA.** A genus of Lilyworts from the Cape of Good Hope, consisting of bulbous plants, with lanceolate lorate often spotted leaves, and erect flower-scapes bearing a raceme of pendulous flowers, the yellow colour being predominant among them. The perianth is six-parted, with the segments connivent into a cylindrical tube, the three exterior ones shorter than the others; there are six stamens, and a three-celled many-ovuled ovary which becomes a membranaceous three-winged capsule, containing but few seeds. *L. pendula*, *luteola*, *tricolor*, and *quadricolor* are familiar inhabitants of our greenhouses, and very ornamental in the spring months. [T. M.]

**LACHNÆA.** Cape shrubs of the *Thymelacææ*, deriving their name from the woolly hairs that densely clothe their flowers. The inflorescence consists of terminal flower-heads frequently surrounded by bracts. The perianth is coloured, tubular, jointed below, the lower portion persistent, the limb divided into four segments, and having attached to it, at its junction with the tube, eight stamens in two rows, and as many scales (petals!) inserted lower down than the stamens, and placed opposite to the divisions of the limb. [M. T. M.]

**LACHNOCAULON.** A genus of *Eriocaulacææ*. They have fibrous roots, a very short stem, linear-lanceolate leaves, sheathed peduncles, and villous capitules of unisexual flowers. They are natives of Virginia, Carolina, Georgia, Florida, and other parts of North America. [J. H. B.]

**LACHNOSTACHYS.** An Australian genus of *Amaranthacææ*, consisting of woolly shrubs, with opposite rigid leaves, and terminal and axillary cylindrical bracted spikes of perfect flowers, with a six or eight-parted scarious perigone, densely woolly outside. [J. T. S.]

**LACHRYMÆFORM.** Tear-shaped; the same as Pear-shaped, except that the sides of the inverted cone are not contracted; as the seed of the Apple.

**LACINIA** (adj. **LACINIATE**). A slash. A deep taper-pointed incision.

**LACINULA.** A small lacinia or slash; also the inflected point of the petals of umbellifers.

**LACIS.** A genus of *Podostemacææ*, consisting of small herbs, natives of Brazilian rivers, having a thick somewhat globular root-stock, numerous stalked palmately-divided leaves and racemose flowers, which differ from those of other genera of the order in their monadelphous stamens, and

in their capsules which consist of two or three equal ribbed valves. [M. T. M.]

**LACISTEMACEÆ** (*Lacistemadæ*). A natural order of dicotyledonous plants belonging to Lindley's violal alliance of hypogynous Exogæ. They are shrubs with simple stipulate leaves, and hermaphrodite or unisexual flowers in axillary catkins. Perianth free, divided, with a large bract; stamen one, hypogynous, the connective separating the antherine lobes, which open transversely; disk often fleshy; ovary one-celled; placentas parietal. Fruit a one-celled two to three-valved loculicidal capsule. Seeds numerous, albuminous, with an aril. Natives of the tropical woods of America. There are about half a dozen species in two genera. [J. H. B.]

**LACISTEMA.** A small genus of arborescent plants of tropical America, from which the order *Lacistemacææ* derives its name. They have simple alternate leaves, polygamous catkin-like flowers, a calyx supported by a bract, no corolla, a solitary stamen surrounded by a somewhat fleshy disk, a capsular one-celled fruit, each cell bearing a solitary seed. In habit the species somewhat resemble pepperworts. Their properties are unknown. [B. S.]

**LACTARIUS.** A large genus of gill-bearing *Fungi*, distinguished by the cellular not filamentous substance of the gills, and the milky juice which is contained in distinct tubes. They are often extremely acrid and dangerous, but some of them, as *L. volcanus* and *L. deliciosus*, are mild and form excellent articles of food. As, however, they are used when pickled in considerable quantities almost indiscriminately by the Russians, it would seem that the dangerous properties are neutralised by the acid. Dogs suffer dreadfully after biting such species as *L. vellereus*, and Dr. Badham had very unpleasant symptoms from simply tasting a few of the spores. The milk of this species leaves a burning sensation in the throat like that of *Euphorbia Lathyris*. When collected it forms a cheesy mass which burns with a bright flame. The milk in many species, though originally white, changes colour when exposed to the air, and sometimes displays brilliant tints, as blue, orange, &c. One or two species have been found in the Himalayas, but Europe and North America are their principal habitats. [M. J. B.]

**LACTESCENT.** Containing lac, or milk.

**LACTEUS.** Milk-white; dull white verging to blue.

**LACTUCA.** A well-known genus of *Compositæ*, deriving its name from the milk-like juice which pervades the plants in their wild state. The genus belongs to the *Cichoraceæ*, and bears the following marks: involucre of a few overlapping bracts, including a few yellow or blue flowers, which are placed upon a scaleless receptacle; fruits somewhat flattened, surmounted by a thread-like beak, and a pappus calyx of

silky hairs. The species are annual or perennial herbs, with erect branching stems, and smooth or spiny leaves, and are distributed over Southern Europe, Central Asia, and North America.

The Garden Lettuces have been so modified by long cultivation, that it is impossible to decide accurately from which species they have originated. Suffice it to say, that the narcotic and sedative principles that are so well known to exist in Lettuce do not occur except to an infinitesimal extent in the succulent young leaves that form so agreeable a salad, but when the flowering stem is thrown up, the sap becomes milky and bitter, and its narcotic properties are then more fully developed. The sedative effects of Lettuces appear to have been known from the earliest times of which we possess any record. Venus, after the death of Adonis, is reported to have found rest for her love-distracted mind by throwing herself upon a bed of Lettuces. Virgil and Oolumella both mention the Lettuce as proper to be eaten as a sequel to more savoury viands, at the end of a repast, as well as for their soporific qualities; and Pliny relates that Augustus was cured of an illness by the use of Lettuces, prescribed by his physician, Musa. The popular opinion respecting the properties of these plants is maintained in our own times by the doggerel that tells us

for want of rest

Lettuce and cowslip-wine probatum est.

Indeed, a substance called *Lactucarium* or Lettuce Opium is prepared from the dried juice of some of these plants, especially *L. virosa*, and is occasionally used as a mild narcotic or sedative where opium is inadmissible.

There are a few British species of this genus: *L. murale*, with thin stalked leaves, and short beaked fruit; *L. virosa*, with sessile prickly leaves, and a spreading panicle; and *L. saligna*, in which the panicle is so contracted as to resemble a spike. [M. T. M.]

The Garden Lettuce, commonly called *L. sativa*, is a hardy annual, whose native country is unknown with certainty, although it is generally supposed to be Asia. It has been cultivated in England since 1562. The plant has large roundish or roundish-oblong entire slightly-toothed milky leaves, which in some varieties are of a deep green, while in others they are of a dingy brown colour. The flower-stem is round, about three feet high, the flowers pale yellow and corymbose. Lettuces appear to have been known and used for salads at a very early period. According to Herodotus, they were served to the royal tables of the Persian kings more than 400 years before the Christian era. It is also recorded that they formed the opium of Galen, the celebrated Greek physician, in A.D. 200, and it was probably the consideration of this historical fact which led to the discovery in our day, by the late Dr. Duncan of Edinburgh, of the drug called *Lactucarium*, prepared from the juice of the Lettuce. The ancient Romans knew but one sort of Lettuce, and this was a variety

with dark-coloured leaves, which they suspected of having an injurious effect on those who ate it; but after the Emperor Augustus was said to have been cured by the free use of Lettuces, suspicion of their deleterious qualities vanished, and great efforts were made not only to cultivate them, but to blanch them so as to remove their bitterness, and thus render them more palatable.

The first English writer on gardening who has noticed the Lettuce is Gerard in 1597. He describes eight varieties as being then cultivated. The number has since greatly increased, and year after year new and improved sorts are brought forward to supply the places of those which have degenerated and are considered unworthy of further cultivation. The whole have been arranged in two divisions or groups, namely, *Cabbage Lettuces*, comprising all those which have round leaves, and form a compact head resembling a cabbage; and *Cos Lettuces*, those having firm and crisp upright oblong leaves, folded over one another. The latter are preferred for salads, while the cabbage kinds, from being more flaccid and milder, are preferred for soups. Although containing but little nourishment, Lettuces are universally esteemed for their emollient and cooling properties, and they are always in great demand. [W. B. B.]

**LACUNA** (adj. **LACUNOSE**). A large deep depression or excavation.

**LACUNOSO-RUGOSE**. Marked by deep broad irregular wrinkles, as the shell of the walnut, or stone of the peach.

**LACUSTRIS**. Growing in lakes.

**LADANUM**, or **LABDANUM**. A resinous product of *Cistus creticus*, and other species.

**LADENBERGIA**. A genus of *Cinchonaceae*, consisting of trees inhabiting Peru. The characteristics of the genus reside in the limb of the calyx, which is very small, somewhat bell-shaped, with triangular teeth; and in the ovary which is surmounted by an eight-lobed disk. [M. T. M.]

**LADY'S BEDSTRAW**. *Galium verum*; also *Pharnaceum Mollugo*.

**LADY'S BOWER**. *Clematis Vitalba*.

**LADY'S COMB**. *Scandix Pecten-Veneris*.

**LADY'S CUSHION**. *Armeria vulgaris*.

**LADY'S FINGERS**. *Antithyllis Vulnearia*.

**LADY'S GARTERS**. *Phalaris arundinacea variegata*.

**LADY'S GLOVE**. *Digitalis purpurea*.

**LADY'S HAIR**. *Briza media*.

**LADY'S LACES**. *Cuscuta*.

**LADY'S LOOKING-GLASS**. *Specularia perfoliata*.

**LADY'S MANTLE**. *Alchemilla vulgaris*.

**LADY'S NAVEL**. *Cotyledon Umbilicus*.

**LADY'S NIGHTCAP.** *Oxyntegia septum*.

**LADY'S SEAL.** *Conwallaria Polygonatum*.

**LADY'S SLIPPER.** *Cypripedium Calceolus*.

**LADY'S SMOOK.** *Cardamine pratensis*.

**LADY'S THIMBLE.** *Campanula rotundifolia*.

**LADY'S THISTLE.** *Carduus Marianus*.

**LADY'S TRACES or TRESSES.** *Neottia spiralis*.

**LADY'S THUMB.** An American name for *Polygonum Persicaria*.

**LADLEWOOD.** A Cape name for the wood of *Cassia Colpoon*.

**LÆLIA.** A beautiful genus of orchids, closely related to *Cattleya*, from which indeed it differs in little if anything, besides having eight pollen-masses instead of four. They are epiphytes, furnished with pseudobulbs which are often elongated clavate and stem-like, thick hard leaves, and terminal scapes of few or many flowers, which are for the most part extremely showy. *L. purpurata* and its allies, *L. superbiens*, *L. majalis*, and *L. prestans*, are some of the finest of the species, which are all South American, and come chiefly from Brazil and Mexico. [T. M.]

**LÆLIOPSIS.** The name of a few epiphytal orchids of the West Indies and South America. They agree with *Cattleya* in all respects except that the flowers are membranaceous, and the veins of the lip bearded. *L. domingensis*, the typical species, is a St. Domingo plant, with two-leaved pseudobulbs, and a slender terminal scape, bearing at the end a few showy flowers, of which the sepals and petals are rather erect than spreading, and the large lip is rolled up round the column, and two-lobed with wavy toothed recurved divisions. [T. M.]

**LÆTIA.** A genus of *Flacourtiaceæ* consisting of small trees inhabiting the woods of tropical America, with dotted or dotless, usually entire and leathery leaves; hermaphrodite or polygamous flowers, arranged in racemes; a highly imbricate calyx; either no corolla or one composed of five petals, yellow or white; an indefinite number of stamens, with very short anthers; and an ovate or three-cornered berry. *L. utetali*, of the Magdalena river, yields a balsamic resin which becomes white in contact with the air, like Sandarach. [B. S.]

**LÆVIGATE.** Having the appearance of being polished, as many seeds.

**LÆVIS.** Free from asperities or hairs, or any sort of unevenness.

**LÆPOENSIA.** A genus of South American *Euphorbiæ*, consisting of tree or shrubs, with opposite leaves, and flowers either solitary in the axils or in terminal racemes or panicles; they are large, white or pale red, with a bilobed eight to ten-

toothed calyx, ten to twelve petals, and twenty to twenty-four stamens; and are succeeded by an incompletely two-celled capsule. [T. M.]

**LAGAROSIPHON.** A genus of aquatic herbs, inhabiting tropical rivers and lakes, and belonging to *Hydrocharitaceæ*. It has smooth parallel-veined leaves, and flowers enclosed in a spathe, and having three sepals and three petals, an indefinite number of stamens, and a succulent fruit. [B. S.]

**LAGASCEA.** A genus of *Compositæ* of the tribe *Vernoniaceæ*, distinguished by the doubly compound flower-heads, each separate floret being enclosed in a four or five-toothed tubular involucre, several of these partial involucre being collected in a general head, surrounded by imbricated leafy bracts. Each floret has a very slender tubular corolla, and a compressed four-angled achene crowned by a very short entire or toothed membranous pappus. There are about seven species, natives of Mexico, all coarse weedy herbs of little interest.

**LAGENARIA.** A genus of *Cucurbitaceæ*, consisting of an annual pubescent musky plant, with alternate heart-shaped leaves, tendrils, clustered single-flowered axillary flower-stalks, and white monocious or dioecious flowers: the males with a bell-shaped five-

*Lagenaria vulgaris*.

parted calyx, five spreading petals, and five triadelphous stamens; and the females with a three-celled inferior ovary, becoming, when mature, a woody pepo. The only species is a native of the warm parts of Asia and Africa. [The fruits are poisonous, or at best of doubtful quality, although some of the numerous varieties have been eaten with impunity.] [J. H. B.]

**LAGENIFORM.** Shaped like a Florence flask.

**LAGENOCARPUS.** The generic name of plants belonging to the order of heath-works; distinguished by having the corolla small, nearly globose, its border slightly five-cleft, the seed-vessel flagon-shaped and one-celled. The species are heath-like shrubs, natives of the Cape. [G. D.]

**LAGENOPHORA.** A genus of *Compositæ*

of the tribe *Asteroides*, consisting of small daisy-like herbs, with the leaves mostly radical, and the small flower-heads growing singly on slender scapes. The numerous spreading ray-florets, either white or pale blue, the numerous yellow tubular florets of the disk, and the flattened achenes without any pappus, are nearly those of *Bellis*, from which genus *Lagenophora* differs chiefly in the achenes being narrowed into a beak at the top. There are about ten species, all Australian, although one species, *L. Billardieri*, extends also into Southern Asia.

**LAGERSTRÖMIA.** A genus of *Lythraceæ*, of which fourteen species are known, all natives of tropical and subtropical Asia, and forming large trees or shrubs, with opposite entire leaves, and terminal panicles of purplish or white flowers. The bell-shaped calyx is cut into six equal-sized lobes, without any intermediate teeth; the corolla consists of six petals, furnished with long narrow claws or stalks; the stamens vary from eighteen to thirty; and the fruit is divided into three or six cells, containing numerous winged seeds. *L. indica* is a shrubby plant, growing eight or ten feet high, with elliptical smooth pale green leaves, and bright rose-coloured flowers, the petals of which are very much curved, having a crumpled but exceedingly beautiful appearance. It is a native of China, and flourishes in our greenhouses.

*L. reginae* forms a magnificent timber tree, yielding a bloodred-coloured wood, which, though open in the grain and soft, is greatly used in India for boat building, and for the knees of ships, on account of its great durability under water. It is called Jarcol, and is common in the peninsula of India, and in Birmanah. The native Indian physicians esteem various parts medicinal, the astringent root being used as a remedy for thrush, its bark and leaves as purgatives, and its seeds as a narcotic. [A. S.]

**LAGETTA.** The tree producing the well-known lace-bark of Jamaica is called in that island by the name Lagetta. The genus belongs to the *Thymelacææ*, and is known by its perfect flowers; its tubular coloured perianth, with a distended tube, contracted throat, and four glands; eight stamens; and a small round hairy fruit, enclosed in the persistent base of the perianth.

The inner bark of *L. linearis* consists of numerous concentric layers of fibres which interlace in all directions, and thus present a great degree of resemblance to lace, whence the common name of the tree. It is reported that Charles II. received, as a present from the governor of Jamaica, a cravat, frill, and pair of ruffles, made of this material; and to this day it is used for bonnets, collars, and other articles of apparel, specimens of which may be seen at the Kew museum, &c. The uses to which this natural lace is applied are not always so unobjectionable as those just mentioned, for it is likewise used in the manufacture of thongs and whips, with which, in former

times at least, the negroes were beaten by their cruel taskmasters. The plant is cultivated in English hot-houses as an object of curiosity. [M. T. M.]

**LAGOECIA.** The name of a genus of umbellifera, characterised by having one half of the fruit abortive, and a deep furrow on one side of that part which attains maturity. The only species is a small annual, a native of Eastern Europe, along the borders of the Mediterranean. [G. D.]

**LAGOPUS.** Hare-footed. A term applied to parts which are so closely covered with long hairs as to resemble a hare's foot; as the rhizome of some ferns, and the inflorescence of some grasses.

**LAGUNARIA.** A malvaceous genus allied to *Hibiscus*, but distinguished from it, and other closely-related genera, by the small size and paucity of the bracts of the involucre; by the presence of a club-shaped style, terminated by a radiated stigma; as well as by the capsule, which is five-celled. The flowers are handsome, and of a pink hue. [There are two forms of the single species, *L. patersoni*, one from Norfolk Island, the other from Queensland.] [M. T. M.]

**LAGURUS.** A genus of grasses belonging to the tribe *Agrostideæ*. It is distinguished by the inflorescence being in round spike-like panicles; glumes scarious, ending in a long-fringed bristle. The soft white silky spikes of flowers, with their protruded awns, give this pretty grass a very remarkable appearance. *L. ovatus*, the only species, is a native of the south of Europe, as well as of some parts of Asia. Though included in the British flora, it is only found in Guernsey. [D. M.]

**LAITRON.** (Fr.) *Sonchus*. — **DE PLUMIER.** *Mulgedium*.

**LAITUE.** (Fr.) *Lactuca sativa*.

**LA-KAO.** A Chinese green dye obtained from *Rhamnus cathartica*.

**LAKE-WEED.** *Polygonum Hydropiper*.

**LALAGE.** A genus of *Leguminosæ* [now usually united with *Bauhinia*, from which it differs only in the much narrower and longer upper lobes of the calyx, which, however, pass gradually into the more usual shape observed in *Bauhinia*]. It consists of four or five shrubs, natives of South west Australia, with alternate ovate lanceolate or linear leaves, and pretty axillary flowers, either yellow or mixed with orange violet and crimson. *L. ornata* has been introduced into our greenhouses with other Swan River *Papilionacææ*.

**LALANG.** *Andropogon carissocus*.

**LALO.** The powdered leaves of *Adansonia digitata*.

**LAMAM.** (Fr.) *Solanum nigrum*.

**LAMARCKIA.** A genus of grasses belonging to the tribe *Festucææ*. The inflorescence is in simple crowded panicles, the spikelets of which are stalked, two-flowered, one fertile and the other sterile. *L. aurea*, the only species of the genus, is a pretty

annual, sometimes cultivated in botanical gardens. It is a native of the south of Europe and north of Africa. [D. M.]

**LAMBERTIA.** A proteaceous genus of small shrubs, natives of extra-tropical Australia, principally on the south and south-west coasts. The flowers are regular, solitary or in clusters, with a four-cleft tubular calyx, the segments of which bear each an anther; and a filiform style with a pointed stigma. The prevailing colour is dark red with occasionally an orange tint. The seed-vessel is ovate, leathery, often bristly, containing two winged seeds. The leaves are entire or toothed, either in threes or verticillate. [R. H.]

**LAMBKILL.** An American name for *Kalmia angustifolia*.

**LAMBRUSQUE.** (Fr.) *Vitis Labrusca*.

**LAMBS QUARTERS.** *Atriplex patula*; in America, *Chenopodium album*.

**LAMBS TOE.** *Anthyllis Vulneraria*.

**LAMBS TONGUE.** *Plantago media*.

**LAMELLA** (adj. **LAMELLAR**). A plate or thin part such as is found at the end of many styles.

**LAMELLÆ, LAMINÆ, LAMELLULÆ.** The gills of fungi: vertical membranous radiating or branching plates belonging to a pileus.

**LAMIACEÆ.** Lindley's name for the *Labiata*: which see.

**LAMINA.** The blade of a leaf; that expanded part which terminates the petiole, if there be one.

**LAMINARIACEÆ.** A natural order of dark-spored *Algae*, consisting of olive-coloured inarticulate sea-weeds, whose spores are superficial and form indefinite cloud-like patches, or cover the whole surface of the frond. Most of them are of considerable size, except *Chorda* which attains a great length, and *Adenocystis*. Some, like *Lessonia*, form submarine forests with stems as thick as a man's thigh, while *Macrocystis* by repeated division attains a length of hundreds of feet. One of the most remarkable is *Nereocystis*, which occurs on the north-west coast of America, and has a stem 300 feet long, which bears above a huge air-vessel six or seven feet long, shaped like a great cask, and ending in a tuft of upwards of fifty forked leaves. This is the favourite resting-place of the sea-otter. *Ecklonia buccinalis*, again, the Trumpet Weed of the Cape colonists, has a stem twenty feet high crowned with a fan-shaped cluster of leaves more than half as long. The stem, which is hollow above, is often used as a siphon or converted into a trumpet. These plants are mostly deep-sea *Algae*, and occur in either hemisphere, both in colder and warmer seas. [M. J. B.]

**LAMINARIA.** An important genus of dark-spored *Algae*, the type of the natural order *Laminariaceæ*. It has no definite leaves, but on the contrary a plane ribless

expansion, which is either simple or cloven. The stem is either short or elongated, and is sometimes of considerable thickness, and either naked or fringed with a crisped expansion. Some of the species, as *L. digitata* and *L. bulbosa*, attain an immense size, and together with *L. saccharina*, which is commonly brought away from the coast to answer the purpose of an hygrometer, yield an enormous supply for the preparation of manure or kelp. One peculiarity about these plants is that the old lamina annually falls off by means of a constriction, and is replaced by a new frond formed from the part beneath. The species delight in the colder seas of the north, and are usually exposed only at low tides. [M. J. B.]

**LAMINATING.** Separating into several plates or layers.

**LAMIUM.** A genus of herbaceous labiate plants distinguished by having four stamens, of which the lower pair are longest; hairy anthers, the cells of which diverge and burst longitudinally; and a corolla of two lips, of which the upper is arched and entire, the lower spreading, two-lobed, and mostly furnished with one or two teeth on each side. The common perennial, *L. album*, or Dead-nettle, received its English name from the resemblance of its leaves to those of the true nettle, from which, however, it may be distinguished at any stage of its growth by its square stem. *L. purpureum* is a common annual weed in cultivated land. French, *Lamier*; German, *Taubnessel*. [O. A. J.]

**LAMOUROUXIA.** A genus of *Scrophulariaceæ*, distinguished by a four-cleft calyx; by a corolla with an elongated somewhat flattened tube, dilated below the throat, and the small three-lobed lower lip shorter than the concave upper one; and by transverse hairy anthers with the cells unusually mucronate. The species are natives of Mexico or of the Andes of South America; they are all herbs, either erect or somewhat climbing, with opposite toothed or divided leaves, rarely quite entire, and handsome flowers, usually scarlet or pink, in terminal spikes or racemes. There are about eighteen species known, most of them very showy plants. None have, however, been yet brought into cultivation, and indeed it is probable that they are more or less parasitical on the roots of other plants, and therefore scarcely capable of being cultivated.

**LAMPOURDE** or **L. GLOUTERON** (Fr.) *Xanthium Strumarium*.

**LAMPRA.** A genus of *Commelynaceæ* from Mexico. They have erect leafy stems, with the lower leaves reduced to sheaths, the upper numerous and lanceolate, and numerous flowers in a sessile head among the leaves. [J. T. S.]

**LAMPRETTE.** (Fr.) *Lychnis Flos-auculi*.

**LAMPSANE.** (Fr.) *Lapsana*.

**LANA, LANUGO** (adj. **LANATE, LANUGINOSE**). Long, dense, curled, and

matted hairs, resembling wool, as in *Verbascum Thapsus*.

**LANCEOLATE.** Narrowly elliptical, tapering to each end. *Lanceolata-hastata* is hastate with the principal lobe lanceolate; and *Lanceolata-sagittata* is sagittate with the principal portion lanceolate.

**LANCE-WOOD.** The light elastic wood of *Duguetia quitarenis*. —, **JAMAICA.** A species of *Lycium*.

**LANDE, or LANDIER.** (Fr.) *Ulex europæus*.

**LANGUE D'AGNEAU.** (Fr.) *Plantago media*. — **DE BŒUF.** *Anchusa officinalis*. — **DE CERF.** *Scotopendrium vulgare*. — **DE CHIEN.** *Cynoglossum officinale*. — **DE MOINEAU.** *Passerina Stelleri*. — **DE SERPENT.** *Ophioglossum vulgatum*.

**LANGUOR.** A name given in vegetable pathology to that condition of plants in which, from unwholesome food, bad drainage, frequent want of water, &c., they fall into a state of premature decrepitude. This is well known in French vineyards under the name of *Goupissure*, and is familiar to all fruit-growers when the subsoil is ungenial. When once this condition is set up, it is difficult of remedy, if not past cure altogether. The removal of the cause is the only rational treatment, and this is not always possible. [M. J. B.]

**LANKESTERIA.** A genus of *Acanthaceæ*, containing two species, natives of Central Africa. They are hairy shrubs with ovate entire leaves, and yellow flowers in short axillary spikes, having a calyx of equal linear sepals, subtended by two bracts; a long slender corolla-tube, and one-sided five-parted limb, two exserted stamens, and a simple capitate stigma. The genus is named after Dr. Lankester, a well-known English botanist. [W. C.]

**LANSA, LANGSAT, or LANSÉE.** The fruit of *Lansium domesticum*.

**LANSBERGIA.** A South American genus of *Iridaceæ*, related to *Phalocallis* and *Cypella*, from the first of which it differs in having the sepals all closed and converging, in the cells of the anther being adherent to the lobes of the style by their whole length, and in the stigmas being minutely crested and not petaloid; while the second is known from it by its stigmas being lobed, acute, and fringed at the upper side with acute horny crests. The outer divisions of the perianth are large and concave, the inner narrow and involute. *L. caracasana* has tuberous roots, simple stems, equitant leaves, and yellow fugacious flowers, spotted with brown or black. [T. M.]

**LANSIUM.** A genus of *Meliaceæ*, confined to the East Indies, and consisting of trees with imparipinnate leaves, and axillary flowers arranged in panicles. The calyx is composed of five sepals; the corolla of five petals; the ten stamens are formed into a tube. The fruit is a corticate berry, having five cells, each cell contain-

ing one or two seeds. This berry has a cooling pleasant taste, and hence they are sometimes cultivated, and sold in the Canton markets. *L. domesticum* (known as *Lansa*, *Langsat*, *Lansch*, *Ayer-Ayer*, or *Bejetian*, in the different languages of the East Indies) has a fruit as large as a pigeon's egg, of a yellowish colour without, and whitish within, which is highly esteemed, and eaten either fresh or variously prepared. The wood is used by the Malays. [B. S.]

**LANTANA.** A considerable genus of *Verbenaceæ*, containing upwards of fifty species, chiefly from tropical or sub-tropical America. They are shrubs, or rarely herbs, with flowers in pedunculate axillary heads, rarely lengthening into spikes. The calyx is small, truncate or sinuately four-toothed; the corolla tube slender, with a spreading four or five-lobed limb; there are four included stamens; the ovary is two-celled; and the fruit is a drupe, the kernel two-celled, or divided into two nuts. [W. C.]

**LAPAGERIA.** A genus of *Philistaceæ*, consisting of twining undershrubs, with alternate cuspidate somewhat reticulate leaves, and solitary one-flowered peduncles, the perianth coloured, six leaved, and somewhat bell-shaped; and the stamens six, in-

*Lapageria rosea*.

serted at its base. The fruit is a one-celled berry, with numerous seeds. They are natives of Chili. *L. rosea*, with its white variety, are two of the most beautiful plants grown in modern greenhouses. [J. H. B.]

**LAPEYROUSIA.** A genus of *Iridaceæ*, consisting of half a dozen species from the Cape colony, allied to *Anomatheca*, in the long slender tube of their perianth, and spreading lobes, but these are much more equal, the stigmas are more deeply cleft, and the capsule is distinctly three-lobed. They have tuberous bulbs, simple stems, with sheathing leaves, and terminal elongated flower-spikes, each flower in the axil of a leafy bract. Three species, *L. lasiophylla*, *L. anceps*, and *L. corymbosa*, were formerly cultivated among our Cape *Iridææ*, but are

not near so showy as many other Ixia-like plants. The same genus has been described under the name of *Oviedo*; and the name of *Lapeyroussia* was also given by Thunberg to a genus of *Compositae*, which De Candolle altered to *Peyroussia*.

**LAPHAMIA.** A genus of *Compositae*, connected in many respects with the tribe *Asteroidae*, but the leaves are usually opposite, and it has not exactly the style of that group. It consists of five species, low herbs or undershrubs, from Texas or New Mexico, with small discoid or radiating yellow flower-heads, and offering no particular interest except to botanists. It is in many respects very near *Perilyta*.

**LAPIDOSE.** Growing in stony places.

**LAPIEDRA.** A small genus of paniciform *Amaryllidaceae*, consisting of a single species, *L. Placiana*, found in Spain. Its leaves are linear obtuse, striped longitudinally with white, and its flowers, white in a many-flowered umbel, have a spreading limb, an imperfect staminal cup, with the filaments short, and dentately winged on each side; a curved and tapering style, and a small trifid stigma. According to Herbert it is the same as *Vagaris parviflora*. [T. M.]

**LAPLACEA.** A genus of *Ternstroemiaceae*, distinguished from *Gordonia* by the short styles, distinct and spreading from the base. There are fourteen species from tropical America, and the Indian Archipelago.

**LAPPA.** *Aralium*.

**LAPPACEOUS.** Bur-like; that is, round or roundish, and covered with small hooks.

**LAPPAGO.** A genus of grasses, belonging to the tribe *Panicaceae*. The inflorescence is in close bundles or heads; spikelets two to five-flowered, with the rudiments of new florets. There are three species, natives of the south of Europe and Africa. [D. M.]

**LAPSANA.** A genus of herbaceous plants mostly annual, belonging to the tribe *Cichoraceae* of compound flowers, and distinguished by having compressed striated fruit destitute of pappus, a naked receptacle, and the involucre composed of a single row of erect scales, with smaller ones at the base. *L. communis*, a hedge weed, is our common Nipplewort. [C. A. J.]

**LARANGA DA TERRA.** A wild orange of Brazil.

**LARBREA.** A section of the caryophyllaceous genus *Stellaria*, of which *S. uliginosa*, the *Larbrea aquatica* of St. Hilaire, is the type; also a synonym of *Malachium*, *M. aquaticum* being the *Larbrea aquatica* of De Candolle. [J. T. S.]

**LARCHE.** *Abies Larix*. —, **CORSICAN.** *Pinus Laricio*.

**LARDIZABALACEAE.** (*Lardizabalada*.) A natural order of dicotyledons, belonging to Lindley's monispermial alliance of dicotyledons *Xylogenia*. Twinning shrubs, with alternate exstipulate leaves, ternary symmetry, and unisexual flowers. They re-

semble *Menispermaceae*, but differ in their spound leaves. Natives of the cooler parts of South America and China. The fruit of some of the plants is eaten. Examples: *Lardizabala*, *Holboellia*. [J. H. B.]

**LARDIZABALA.** One of the two American genera, belonging to the small order *Lardizabalaceae*, and consisting of two species, both climbing shrubs, with rather large compound leaves, the six or nine leaflets disposed in two or three sets containing three each. The flowers are of separate sexes, borne on distinct plants, the males in many-flowered racemes, and the females solitary. Both sexes have a calyx of six fleshy egg-shaped sepals, arranged in a double series, the inner ones narrower than the outer. The ovaries ripen into many-seeded berries. Both species are found in Chili, extending as far south as Concepcion. One, *L. biternata*, which generally has leaves composed of six leaflets, is sufficiently hardy to withstand the cold of our winters, when trained against a wall, and its dark glossy evergreen foliage, and drooping spikes of deep purple flowers, render it very ornamental. In Chili, a very tough fibre is obtained from its stems and made into cordage; and its fruit, containing a sweet-tasted pulp, is sold in the markets. [A. S.]

**LARIX.** See **ABIES**, under which head information is given respecting the well-known European Larch; hence, it is here only necessary to add what is there omitted, viz. that the American Larch, *Abies* or *Larix pendula*, is the tree known to the Canadians as the Tamarack, and which furnishes an important feature in the appearance of the Canadian forests. [M. T. M.]

**LARKSPUR, LARKHEEL, LARK'S OLAW.** *Delphinium*.

**LARME DE JOB, or LARMILLE.** (Fr.) *Cotix Lachryma*.

**LARNAX.** Peruvian and Mexican herbs, constituting a genus of *Solanaceae*, closely allied to *Physalis*, with which genus, among other things, they concur in the fact that, as the berry-like fruit ripens, the calyx increases in size and assumes the appearance of a bladder surrounding the fruit. The points of distinction are to be sought for in the shape of the calyx, which is here tubular, angular, and five-toothed; and in that of the corolla, whose limb is somewhat bell-shaped, and divided into five acute spreading lobes. [M. T. M.]

**LAROECHA.** *Rochea*.

**LARREA.** A genus of *Zygophyllaceae*, of which four species, three of them found in Chili and Paraguay, are known. They are strong-scented evergreen shrubs, with low branched stems, knotty jointed branchlets, opposite leaves, consisting usually of a single or rarely of several pairs of unequal-sided leaflets, and terminal flowers, with five sepals, five yellow petals, ten stamens, and a five-celled ovary, each cell maturing a single thin-shelled seed.

*L. mexicana*, the Orocote plant of the

**Americans**, is a shrub growing from four to six feet high, very abundant in some parts of Mexico, forming a dense and almost impassable scrub, particularly on the borders of the Colorado desert, where its luxuriant growth puts a stop to the drifting sand. It is a sure sign of a sterile soil, for wherever it flourishes little else can be found, and although it gives the scenery a beautifully verdant appearance, its strong crocodile-like odour renders it so repulsive that no animal will touch it. Moreover, as it can scarcely be made to burn, it is useless even for the purpose of fuel. The resinous matter to which the odour is due abounds in all parts of the plant. The Pimos Indians collect and form it into balls which they kick before them as they journey from one point to the other of their trail. It is also used in rheumatism. [A. S.]

**LASEGUEA**. A genus of dogbanes, distinguished by having the calyx five-parted, the divisions oblong, two glands at the base of each; the corolla shorter than the calyx, its border five-lobed; a ring of hairs at the point of origin of the stamens; and the glands of the nectary five. The species are shrubs or undershrubs, natives of Brazil, having opposite and shortly-stalked leaves, which are cordate and entire; the racemes of flowers are terminal, and the individual flowers are supported on stalks which are longer than the linear-lanceolate bracts. [G. D.]

**LASER**. (Fr.) *Laserpitium*.

**LASER CYRENAICUM**. The Ass dulcis, *Thapsia garganica*.

**LASERPITUM**. A genus of umbellifers, distinguished from its allies by the fruit having eight prominent wing-like appendages. The species are perennial herbs, chiefly found in South-eastern Europe. Some of them are employed as domestic remedies, on account of their possessing some degree of aroma. [G. D.]

**LASERWORT**. *Laserpitium*; also *Thapsia Laserpitii*.

**LASIA**. A genus of onoriads, very closely allied to *Pothos*, but distinguished from that genus by its sessile spadix and its pendulous ovules. The species are Indian plants, with more or less of a creeping habit, thickly beset with strong spines; and the pinnately-divided leaves have sheathing leaf-stalks. [M. T. M.]

**LASIAGROSTIS**. A genus of grasses belonging to the tribe *Stipeæ*. The species which were referred to it are described under *Stipa* by Steudel, who makes *Lasiagrostis* a section of that genus. [D. M.]

**LASIANDRA**. A genus of *Melastomaceæ*, consisting of trees or shrubs with four-angled branches, opposite or verticillate entire ribbed leaves, and panicled showy flowers, with five petals and a capsular fruit. There are about forty species, natives of tropical America. [J. H. B.]

**LASIOLEPIS**. This genus is stated to

differ from *Harrisiopsis* in its five-parted flowers only, and therefore would be better merged therein. The name is applied to a shrub of the Philippine Islands, with wavy spiny branches and compound leaves, and refers to the hairy scales that are attached to the base of the stamens in this and other genera of *Simarubaceæ*. [M. T. M.]

**LASIOPETALUM**. A genus of *Soroeæ*. *Macra*, the type of the tribe *Lasiopetaleæ*, exclusively Australian, distinguished by hermaphrodite flowers with the petals either wanting or reduced to small scales; and by the stamens, of which five only bear anthers, and which are only shortly united at the base, or quite free. The genus is characterised in the tribe by anthers opening in terminal pores, and by the calyx not marked with the parallel prominent ribs of *Soroeæ*. It consists of about twenty-five Australian species, low shrubs, more or less clothed with stellate hairs. The leaves are usually alternate, and more or less toothed or lobed, rarely entire or opposite; and the flowers are in short racemes, with the calyx at first herbaceous and downy, often enlarging as the flower advances, and coloured blue or reddish, so as to assume the appearance of a corolla. A few species occasionally occur in our collections of greenhouse plants.

**LASIOSPERMUM**. A genus of South African plants, belonging to the chamomile group of the *Compositæ*, and readily recognised by the dense rusty wool which completely envelopes the ripe achenes. The three species are erect branching herbs, with pinnatisect leaves, and solitary whitened flower-heads, having much resemblance to those of the feverfew. [A. A. B.]

**LASIOSTOMA**. The name of a cinchonaceous shrub, native of New Ireland. It has sessile flowers in axillary heads; a cup-shaped calyx limb; a short-tubed four-parted funnel-shaped corolla; four anthers; and a succulent two-celled fruit. The name is also synonymous with *Rouhihamon*, a genus of *Loganiaceæ*. [M. T. M.]

**LASTHENIA**. A genus of *Compositæ*, of the tribe *Heliantheæ*, consisting of three or four Californian or Chilian annuals, with opposite linear leaves, and small flower-heads, with a yellow ray or entirely discoid. The involucre is campanulate, of several united bracts, the receptacle without scales, and the achenes with a pappus of about ten chaffy scales or none at all. They grow in wet places, and appear to be uninteresting weeds.

**LASTREA**. A large genus of polypodiaceous ferns of the *Aspidium* group, including all those species in which the veins are free, and the indurium is kidney-shaped. It is one of the three great divisions into which the old genus *Aspidium* was broken up by modern pteridologists, the others being *Nephrodium* and *Polystichum*. The former, which also has reniform indusia, is known from it by the conveniently anastomosing venation, that of *Lastrea* being

quite free; while the other, which is free-veined, is separated by its petiole indusia. *Sagittaria*, another group with reniform indusia, is separated by its compoundly anastomosing veins. The species are well represented in gardens, and consist principally of those whose veins are simple, as in *L. lucida*, and those whose veins are forked, as in *L. marylandica*. Several of our British species belong to this genus, of which, indeed, *L. Filix-mas* is the type. A similar name, *Lastrea*, was formerly given to certain species supposed to be allies of *Poly-podium*, and this name is sometimes mistakenly used for the modern group, which was defined by Presl under the name of *Lastrea*. A fine Japanese species, *L. Sieboldii*, has several series of sori. [T. M.]

**LATANIA.** A small genus of African palms, forming trees of twenty or thirty feet high, their stems marked with circular scars, and bearing at the summit a tuft of fan-shaped leaves, from the lower part of which the branching flower-spikes, sheathed in incompete spathe, emerge. The two sexes of flowers grow on separate trees, the males being disposed in many-flowered, the females in fewer-flowered, cylindrical catkins. Both have three sepals and three petals. The fruits contain three rough stones, covered with a bony network. The round or somewhat three-sided yellowish fruit of *L. Commersonii* is about the size of a small apple, covered with a tough rind, and containing a small quantity of pulp, which the negroes eat in spite of its very disagreeable flavour. It is a native of Bourbon and Mauritius, and is one of the palms cultivated in the hot-houses of European gardens. [A. S.]

**LATERA.** Sides; the two opposite sides of a stem or similar body.

**LATERAL.** Fixed near or upon the side of anything.

**LATERINERVED.** Straight-veined, like the leaves of grasses.

**LATERITIUS.** Red brick colour.

**LATEX.** The same as Lac (which see), but the term is extended to any kind of viscid fluid conveyed in laticiferous vessels, whether opaque or not. Latex granules are particles of starch or other matter, floating in the latex.

**LATHEREA.** Toothwort, a curious herbaceous plant belonging to the *Orobanchaceae*, and having the habit of an *Orobancha*, from which it may be distinguished by its four-cleft calyx. *L. Squamaria*, the only species, has a simple fleshy erect stem, about a foot high, leafless, but furnished with numerous fleshy scale-like bracts; and dull purple or flesh-coloured drooping flowers, which grow in two rows on the same side of the stem. The root, which is parasitic on the roots of various trees, is branched and clothed with numerous fleshy scales, which, from their resemblance to human front teeth, originated the English name. In accordance with the common fallacy of

the old herbalists, its tooth-like roots were considered a specific for tooth-ache, but the plant has no known virtues. French, *Almandesine*; German, *Schuppenwurz*. [G. A. J.]

**LATHYRUS.** A genus of *Leguminosae*, of the suborder *Papilionaceae*, very nearly allied to *Vicia*, but distinguished by the style, which is flattened below the stigma, quite glabrous on the outer side, but more or less downy on the inner face for some way below the stigma. There are a considerable number of species, mostly known by the name of Peas. Indeed, the common pea (for which see *Pisum*) ought, strictly speaking, to be included in the same genus, the characters by which botanists have been in the habit of separating it being of very trifling value. The true *Lathyrus* are dispersed over various parts of the globe, chiefly in temperate climates or in mountain ranges within the tropics. They are herbs with weak stems, sometimes climbing, the leaves usually pinnate, with fewer and larger leaflets than in the vetches, and often only one pair or even none at all, the common stalk always ending in a point or a tendril. The flowers are solitary or in racemes, purple, red, blue, white, or bright yellow, and often very handsome.

Several species are in cultivation. *L. odoratus*, the Sweet Pea of our gardens, an annual well known for its showy sweet-scented flowers, two or rarely three together on each peduncle, is a native of southern Sicily, where it is not uncommon wild, in cultivated as well as in bushy places. *L. latifolius*, cultivated in flower-gardens as the Everlasting Pea, is a slight variety of *L. sylvestris*, a species dispersed over the greater part of Europe, and known by its perennial root-stock, its single pair of lanceolate or rarely ovate leaflets, and its loose racemes of rather large reddish-purple scentless flowers. The garden variety has broader leaflets, and larger, more richly coloured, flowers. *L. sativus*, an annual with leaflets in single pairs, bluish flowers growing singly on each peduncle, and winged broad short pods, is extensively cultivated in Southern Europe, under the name of Jarosae or Gesse, for its seed, which is eaten in the same way as the chick pea (*Cicer*), but is of superior quality; the pod is also eaten green, and the whole plant is sometimes cut for forage, while the peas are much given to poultry. *L. Cicera*, an annual like the last but with red flowers, is also grown occasionally for its peas, under the names of Jarosae pola-carrae, or lesser chick pea, but is of a still inferior quality, and said to be sometimes very unwholesome. *L. tuberosus*, a very handsome perennial, with purplish-red often sweet-scented flowers, not uncommon in cornfields in several parts of Europe, has been recently detected in Essex. In countries where it is abundant, its tuberos roots are much sought after for eating, boiled, or baked like potatoes, but it is now much less common than it used to be. *L. pratensis*, common in our meadows, has short racemes

of yellow flowers, and forms an excellent pasture. *L. Aphaca*, an annual with solitary small yellow flowers, is curious from the leaves, which have no real leaflets, but are reduced to a tendril between two large leaf-like stipules; and *L. Nissolia*, an annual with solitary pale red flowers, has neither leaflets nor stipules; but the leaf-stalk is flattened so as to resemble a linear grass-like leaf. The genus *Orobus*, distinguished only by the tendril being reduced to a short point, is now united with *Lathyrus*, and includes the British species *L. macrorrhizus* (*Orobus tuberosus*) and *L. (Orobus) niger*.

**LATICIFEROUS VESSELS.** A continuous anastomosing tubular tissue in which latex is conveyed. It is probably a modification of cellular tissue, formed in a similar way to bothrenchyma.

**LATIPES.** A genus of grasses belonging to the tribe *Panicææ*. *L. senegalensis*, the only species, is now included under *Lappago*. [D. M.]

**LATOURIA.** A section of *Lechenaultia* consisting of a North Australian herb, with alternate filiform leaves, and flowers opposite the leaves, having a tubular calyx and a partially two-lipped corolla. They are distinguished by the capsule which is slightly valvate, and by the seeds which are cylindraceous. [R. H.]

**LATROBEA.** An Australian genus of *Leguminosæ*, nearly allied to *Lotus*, differing in the strophilote seeds, and the leaves concave or with involute not revolute margins; and to some species of *Pultenaea*, from which it

**LATTICE-LEAF-PLANT.** *Oncandra fenestrata*; also *O. Bernieriana*.

**LATRACEÆ.** (*Laurinææ*, *Lauri*, *Laurelæ*.) A natural order of dicotyledons belonging to Lindley's daphnoid alliance of perigynous Exogens. Trees with exstipulate, usually alternate, dotted leaves; perianth four or six-cleft in two rows; stamens often eight to twelve, the three or four innermost being abortive staminodia, and the outer fertile; filaments sometimes bearing glands; anthers two to four-celled, opening by recurved valves; ovary superior, one-celled, with one or two pendulous ovules. Fruit a berry or drupe; pedicel often thickened; seed solitary, exalbuminous; embryo with large cotyledons. They

species. *Cinnamomum zeylanicum* yields cinnamon bark. *C. Cassia* supplies cassia bark. *Camphora officinarum*, a native of China, Japan, and Cochin China, yields camphor. *Persea gratissima* furnishes the fruit called avocado pear or alligator pear. *Nectandra Rodiei* is the name of bebeeru bark. *Bassafras officinale* is the sassafras tree of America. *Laurus nobilis*, a tree of the south of Europe and the Levant, is the victor's laurel or sweet-bay. [J. H. B.]

**LAUREL.** *Laurus*; also *Cerasus Laurocerasus*. — of Panama. *Cordia Geraschankus*. — of New South Wales. *Cryptocarya glaucescens*. —, ALEXANDRIAN. *Ruscus racemosus*. —, AMERICAN. *Kalmia*. —, BAY. *Laurus nobilis*. —, CHERRY. *Cerasus Laurocerasus*. —, COFFEE. *Daphne Laureola*. —, GREAT. An American name for *Rhododendron maximum*. —, GROUND. *Epigæa*. —, JAPAN. *Aucuba japonica*. —, MOUNTAIN. *Oreodaphne bullata*. —, PORTUGAL. *Cerasus lusitanica*. —, NATIVE, of Tasmania. *Anopterus glandulosa*. —, NEW ZEALAND. *Corynocarpus lavigata*. —, POETS. *Laurus nobilis*. —, ROMAN. *Laurus nobilis*. —, SEABIDE. *Xylophylla latifolia*. —, SHEEP. *Kalmia angustifolia*. —, SPURGE. *Daphne Laureola*.

**LAUREL-CHERRY.** *Cerasus Laurocerasus*.

**LAURELIA.** A genus of *Atherospermaceæ*, one species of which is confined to Chili, and the other to New Zealand. They are tall trees, exhaling a powerful aromatic odour when bruised or broken. The leaves are ovate or oblong lanceolate serrated, and of smooth leathery texture; the flowers are small and inconspicuous, borne in short racemes, the two sexes being usually upon different trees, their calyx cut into from five to fifteen segments, arranged in several series, those of the males containing from seven to fourteen stamens, and those of the females numerous scales in the place of stamens, and several hairy ovaries.

*L. Nova Zelandia*, called Pukatea by the natives, is one of the largest of the New Zealand trees, attaining a height of one hundred and fifty feet, with a trunk from three to seven feet in diameter, encircled at the base by huge buttresses fifteen feet thick. It affords a soft yellowish timber which is much used by the colonists for boat-building. The aromatic seeds of the Chilian species, *L. sempervirens*, are used as a spice in Peru, and are often called Peruvian Nutmeg. [A. S.]

**LAURENOLACEÆ, LAURENCIA.** A natural order and genus of rose-spired *Algae* belonging to the series with tufted spore-threads. The capsules are external, and contain a distinct nucleus with a basal placenta, and the fruit is confined to the terminal joint of the spore-threads. The frond is four-articulate, solid or tubular, and septate, the cells on the surface minute, and the tetraspores scattered irregularly through the branchlets. The type of the order is *Laurencia*, which has a solid cartilaginous round or compressed four-articulate compound pinnate or rarely forked frond, studded with ovate capsules, opening by a terminal pore. This genus contains some of our more common *Algae*, as *L. obtusa* and *pinnatifida*, the latter of which is sometimes eaten under the name of Pepper Dulse, while *L. obtusa* forms the greater part of what is now sold in the shops as Coralline Moss. Both of these are found equally in the north and south

hemispheres. No *Alga* are more subject to variation. [M. J. B.]

**LAURENTIA.** A genus of *Lobeliaceae*, consisting of low-growing annual plants, with tufted leaves, axillary or racemose inflorescence, and blue or rose-coloured flowers. They are natives of extra-tropical Australia, and of the Cape of Good Hope. The genus is mainly distinguished from its allies by the ovate calyx tube, and the straight tube of the corolla, whose limb is divided into five nearly equal segments, or is somewhat bilabiate. [M. T. M.]

**LAURÉOLE.** (Fr.) *Daphne Laureola*.

**LAURESTINE, or LAURUSTINUS.** *Viburnum Tinus*.

**LAURIER.** (Fr.) *Laurus*. — **ALEXANDRIN.** *Ruscus racemosus*. — **ALEXANDRIN DES ALPES.** *Streptopus amplexifolius*. — **AMANDIER.** *Cerasus Lauro-cerasus*. — **A SAUCE.** *Laurus nobilis*. — **AU LAIT.** *Cerasus Laurocerasus*. — **AUX ORÈMES.** *Cerasus Laurocerasus*. — **AVOCAT.** *Persea gratissima*. — **BENJOIN.** *Benzoin odoriferum*. — **CERISE.** *Cerasus Laurocerasus*. — **D'APOLLON.** *Laurus nobilis*. — **DE PORTUGAL.** *Cerasus lusitanica*. — **DE SAINT ANTOINE.** *Epibotium angustifolium*. — **DU MI-SSISSIPI.** *Cerasus caroliniana*. — **SASSAFRAS.** *Sassafras officinalis*. — **TIN.** *Viburnum Tinus*. — **TULPIER.** *Magnolia grandiflora*.

**LAURIER-ROSE.** (Fr.) *Nerium Oleander*. — **DES ALPES.** *Rhododendron ferrugineum*.

**LAURINE.** (Fr.) A kind of olive.

**LAURUS.** Under the common name of Laurel many very different plants are met with in gardens, but Bay or Noble Laurel, *L. nobilis*, is the only one which is properly so called. The genus *Laurus* gives its name to the order *Lauraceae*, and is distinguished by the leaves, which have a single midrib, and by the twelve stamens all of which are fertile, with two-celled anthers, and two glands, one at each side. In the female flower the succulent fruit is surrounded by the persistent base of the calyx. The Bay Laurel, *L. nobilis*, is a native of the south of Europe, and is commonly cultivated in this country as an evergreen shrub, as it usually proves hardy enough to resist our winters. In its native countries it attains a height of thirty or forty or even sixty feet, but never loses its shrub-like character. Its leaves are evergreen, lance-shaped, with an agreeable aromatic slightly bitter taste; its flowers are yellowish and inconspicuous, and its fruits are succulent and of the size of a small cherry. From their agreeable flavour the leaves of the Bay are made use of by cooks and confectioners, and without the hazard that attends upon the use of the leaves of the cherry-laurel, which are frequently substituted for those of the Bay. The dried figs that are imported into this country are usually packed with these leaves. From the fruit is expressed a butter-like

substance known as oil of Bays, which has been used as an external stimulant, and still finds a use in veterinary medicine.

The Laurel is one of the plants called *Daphne* by the ancients, and is figured under that name in the Rincevent MS. of Dioscorides, now in the possession of Sir Thomas Phillips. The branches of this plant were likewise used to form the crowns placed on the heads of the heroes of antiquity, and on the statues of the gods: hence perhaps the name from *laus*, praise, and also the specific name 'noble.' See **BENZOIN**, **CINNAMOMUM**, **CAMPHORA**, **PERSEA**, and **SASSAFRAS**. One of the Laurels is figured in Plate 11 d. [M. T. M.]

**LAVANDE MÂLE.** (Fr.) *Lavandula Spica*.

**LAVANDULA.** A genus of *Labiata* known by its ovate ribbed calyx; its two-lipped corolla, the upper lip of which is two-lobed and the lower three-lobed; and its four stamens which are bent downwards. The common Lavender, *L. vera*, is a native of the south of Europe, but is largely cultivated in this country for the sake of its agreeable perfume, and for the oil on which this property depends. It is an undershrub two to three feet high, with ascending striated branches; linear hoary leaves, which in the young state are rolled under at the edges; and greyish-blue flowers which are borne in compact spikes. The flowers and leaves of this plant are stated to have been used by the ancients to perfume their baths, whence perhaps the name, from *lavare*, to wash. They are still used by housewives to perfume their stores of linen, and prevent the access of moth. The essential oil of Lavender is procured by distillation from the flowers, and is much prized for its agreeable odour; when dissolved in spirits of wine, and mixed with other perfumes, it forms the much-appreciated Lavender Water. The Red Lavender drops of the druggists consist merely of a spirituous solution of the oils of Lavender and Rosemary, mixed with certain aromatic and colouring materials. They are used frequently as a stimulant and cordial in cases of flatulence, hysteria, or faintness.

Another species, *L. Spica*, yields oil of Spike, which is of a darker colour and less agreeable perfume than true oil of Lavender. The oil procured from this plant, together with that from *L. Stachas*, are used by painters on porcelain, and by artists in the preparation of varnishes. The last-named plant is employed as an expectorant and antispasmodic by the Arabs.

Besides these, other species natives of the Canary Isles, Madeira, &c., are cultivated in greenhouses; some of them are remarkable for the elegance of their leaves, which are more or less deeply divided in a pinnate manner. *L. Stachas* is moreover remarkable for the large size of some of the uppermost bracts of the spike, which are of a beautiful violet colour. [M. T. M.]

**LAVANDE.** (Fr.) *Galega officinalis*.

**LAVATERA.** A genus of *Malvaceæ* chiefly confined to Europe and Western Asia, abounding principally in the countries bordering on the Mediterranean, and apparently preferring the vicinity of the sea, one species extending as far north as the British Isles. They are shrubby plants, sometimes having woody stems two to three feet high, their leaves being roundish and lobed, and their flowers having a three to six-lobed involucre, a five-lobed true calyx, five or more carpels or ovaries arranged in a circle round a thick axis, and as many styles. *L. arborea*, the Sea or Tree Mallow, is a common south-west European plant, growing upon rocks on the sea-shores, occasionally found in a wild state on the south and west coasts of England and Ireland, and also on the Bass Rock in the Frith of Forth, but more frequently seen in places where it has escaped from cultivation, it being a common plant in sea-coast cottage gardens. In a wild state it is usually three or four feet high, but when cultivated it attains a height of eight or ten feet, and its stem is three or four inches thick. The pale purple flowers grow in long racemes at the ends of annual flowering branches. Like the rest of mallowworts the Tree Mallow contains an abundance of mucilaginous matter, and a large quantity of fibre. It has lately been recommended for cultivation as a fibre-yielding plant, but the quality of its fibre is not very good. [A. S.]

**LAVATÈRE D'HYÈRES.** (Fr.) *Lavatera Olbia*.

**LAVENDER.** *Lavandula vera*. —, FRENCH. *Lavandula Spica*. —, SEA. *Statice*.

**LAVENDER COLOUR.** Pale blue, with a slight mixture of grey.

**LAVENDER-COTTON.** *Santolina*.

**LAVER.** A condiment prepared from the common *Porphyra*, which is greatly esteemed by some, while to others it is an object of unmitigated disgust. The taste for it, like that for olives, is only acquired by use. The best way of preparing it for table is to mix the quantity required for immediate use with a few tablespoonfuls of stock, and a little lemon-juice. It is then to be made quite hot in a well-tinned or silver saucepan, and poured upon toast. Green Laver is *Ulva latissima*. [M. J. B.]

**LAVOIR DE VÉNU.** (Fr.) *Dipsacus sylvestris*.

**LAVOISIERA.** A genus of *Melastomaceæ*, consisting of shrubs with dichotomous erect branches, opposite decussate sessile leaves, and terminal bracteated showy flowers, with a five to ten-toothed calyx, five to ten petals, and ten to twenty stamens, the anthers with a short beak, and a single pore. The fruit is a capsule covered by the calyx. There are about twenty species, natives of Brazil. [J. H. B.]

**LAVRADIA.** A genus of *Sauvagesiaceæ*, consisting of smooth undershrubs, with

crowded alternate stipuled leaves, and white or rose-coloured panicles, bracteated flowers, having a five-parted calyx, five hypogynous convolute petals, hypogynous stamens, the outer ones petaloid staminodia, and a free ovary three-celled at the base and one-celled at the apex. The few species are natives of Brazil. [J. H. B.]

**LAWRENCILLA rosea** is a very pretty dwarf Swan River annual, described by Lindley as forming a genus of *Compositæ*, of the tribe *Gnaphaliceæ*. It resembles *Rhodanthe*, but is said to be handsomer, and differs in the achenes being covered with long clavate glands, and in the pappus not being plumose. The leaves are said to be fragrant. Bentham unites it with *Helichrysum*.

**LAWRENCIA.** The name of a small malvaceous herb of Taamania, having small flowers arranged in densely-crowded spikes, provided with numerous bracts; each flower has an involucre of three segments, and an inner bell-shaped five-cleft calyx, five lance-shaped petals, and reniform two-valved anthers. The fruit consists of five one-celled one-seeded indehiscent capsules. It is now referred to *Fraxinanthus*. [M. T. M.]

**LAWSONIA.** The celebrated Henna of the East, *L. alba*, or as sometimes called *L. inermis*, the only species of this genus of *Lythraceæ*, is a dwarf shrub eight or ten feet high, bearing smooth oval lance-shaped entire leaves, and panicles of small white sweet-smelling flowers, which are used by Buddhists as offerings to their deities. These flowers have a four-parted persistent calyx without intermediate teeth, four spreading petals, eight stamens, and a four-celled ovary. The fruit is about as large as a pea.

This shrub is grown throughout India, Kurdistan, Persia, Syria, Egypt, and the north of Africa, and the use of its powdered leaves as a cosmetic is very general in all these countries, the practice having descended from very remote ages, as is proved by the evidence of Egyptian mummies, the parts dyed being usually the finger and toe nails, the tips of the fingers, the palms of the hands, and the soles of the feet, to all of which it imparts a reddish-orange colour, which is considered by the Oriental fair sex greatly to enhance their beauty! It is also used by the men for colouring their beards, and by the Arabs for dyeing the manes and tails of their horses. The preparation of henna usually consists in simply reducing the leaves and young twigs to a fine powder, but sometimes powdered catechu or lucern leaves are mixed with it. When required for use, this powder is made into a pasty mass with hot water, and then spread upon the part to be dyed, being generally allowed to remain on for one night. Henna is the Persian name of the shrub, Khenna the Egyptian, Al Khanna the Arabic, and Mende the Indian, while in England it is often called Egyptian Privet, and in the West Indies, where it is naturalised, it goes by the name of Jamaica Mignonette. [A. S.]

**LAXMANNIA.** A genus of Australian herbs, belonging to the *Liliaceæ*. They have the habit of *Polycarpon*, with filiform procumbent stems, setaceous-acerose leaves, the radical ones crowded, and small purple or white flowers, arranged in sessile axillary or shortly-stalked terminal heads, the perianth being membranaceous, six-parted, and persistent. [J. T. S.]

**LAX, LAXUS.** Said of parts which are distant from each other, with an open arrangement, such as the panicle among the kinds of inflorescence.

**LAYIA.** A genus of *Compositæ*, of the tribe *Heliantheæ*, including *Madaraglossa* of De Candolle. It is near to *Madia*, differing chiefly in the achenes not being laterally compressed, and all, at least those of the disk, being crowned by a pappus of ten to twenty bristles, which are plumose or villous, with long hairs at the base. It consists of seven or eight annual or biennial herbs, natives of California or Oregon, usually pubescent or hirsute and often glandular, with alternate leaves, the lower ones often cut or lobed, and flower-heads more showy than in *Madia*, with white or yellow rays. The name of *Layia* has also been given to a Chinese leguminous tree, which has since been united with *Ormosia*.

**LEAD-COLOURED.** Slate-coloured, with a slight metallic lustre.

**LEAD PLANT.** An American name for *Amorpha canescens*.

**LEADWORT.** *Plumbago*.

**LEADWORTS.** Lindley's name for the *Plumbaginaceæ*.

**LEAF.** An expansion of the bark, placed asymmetrically with regard to other leaves, and performing the offices of respiration and digestion when in its perfect condition. In an incomplete or modified state, it constitutes all the forms of the appendages of the axis. It is simple when not cut into separate parts, and compound when divided into other distinct parts.

**LEAF-BUDS.** Buds from which leaves only are produced: they are called *normal* when produced at the axis, *adventitious* when they occur in places not axillary, and *latent* when they are undiscoverable by the naked eye.

**LEAFLET.** One of the divisions of a compound leaf.

**LEAF-LIKE.** The same as Foliaceous.

**LEAF-STALK.** The (unexpanded) base of a leaf, connecting it with the stem.

**LEAF-CUP.** *Polymnia Uvedalia*.

**LEAF, WALKING.** *Campptosorus rhizophyllus*.

**LEATHER-FLOWER.** *Clematis Viorna*; also *Byrranthæa*.

**LEATHER-WOOD.** *Biros*; *Coratopetalum*.

**LEATHERY.** The same as Coriaceous.

**LEAVENWORTHIA.** A genus of *Cruciferae* from North America, formerly included in *Cardamine*, from which it differs by having the seed wing-margined and the embryo nearly straight, or with the radicle only slightly bent towards the edge of the cotyledons. The flowers also are yellow, which is never the case in *Cardamine* and *Dentaria*. [J. T. S.]

**LEBECKIA.** A South African genus belonging to the papilionaceous suborder of *Leguminosæ*. The species are shrubs with ternate leaves, or occasionally with one leaflet or with none, the leaf-stalk being then leafy and supplying the place of the true leaf. The flowers have a five-toothed calyx; an ovate standard bent downwards, and a rather sharp keel; ten monadelphous stamens; and a cylindrical many-seeded pod. [M. T. M.]

**LEBO.** The leaves of the Bread-fruit tree used in the Pacific Islands sewed together to cover food in cooking, in order to keep in the steam.

**LECANIODISCUS.** A name given by Planchon to a sapindaceous tree or shrub from tropical Africa, which appears, however, scarcely to differ generically from some species of the large genus *Cupania*.

**LECANOPTERIS.** A name proposed by Blume for a Javanese polypodiaceous fern, remarkable chiefly for its coriaceous pinatifid fronds, with roundish ovate segments, having the sori immersed in the concave or cupuliform marginal teeth, which are turned back on the surface of the frond. It belongs to the series with the venation anastomosing, and has free included veinlets within the areoles. Sir W. Hooker and Mr. J. Smith both regard it as an abnormal form of *Pleopeltis loma-rioides*. [T. M.]

**LECANORA.** A genus of crustaceous lichens belonging to the order *Parmeliaceæ*, resembling frequently *Lecidea* in appearance, but always distinguished by the border being formed from the thallus. *L. tartarea* affords the Cudbear of commerce; but the most remarkable species in the genus are *L. cauculeta* and *affinis*, which are found in Armenia and Algeria, blown about and heaped up by the winds, and are ground up with corn in times of scarcity to eke out the scanty supply. They are, however, a bad substitute, as they contain 66 per cent. of oxalate of lime. These species are either slightly lobed like the brain, or composed of close-packed branches. Their early stage of growth has not been observed, but it is probable that they are attached when young, and become free by a sort of hypertrophy, which nourishes the plant everywhere except at the very base—at least an analogous form of *Parmelia saxatilis* has been described. The natives consider these lichens to be the Manna of the Israelites, and believe that they fall from heaven, as they see them occasionally borne by tempests from distant tracts. [M. J. B.]

**LECHEA.** A genus of *Oistacea*, differing from *Helianthemum* in the petals being reduced to three small ones or entirely deficient, in the fringed stigmas, the ovules two only to each placenta, and in the seeds having a straight embryo. There are four or five species, natives of North America, all low slender much-branched herbs or undershrubs, with numerous small greenish or purplish flowers of no beauty.

**LECHEGUANA HONEY.** A dangerous kind of honey, supposed to be furnished by *Paulinia australis* and *Serjania lethalis*.

**LECHENAULTIA.** *Lechenaultia*.

**LECIDEA.** The typical genus of *Lecidinet*, consisting of crustaceous lichens, for the most part adhering closely to rocks or trunks of trees. The weather-stains on stones and the grey patches on trees belong principally to this genus, which is diffused over the whole face of the globe. The fruit-bearing shields have the border coloured like the disk, which is always well-defined in the young plant, though sometimes obliterated in age. [M. J. B.]

**LECIDINEI.** A natural order of lichens in which the open orbicular disk of the fruit is contained in a distinct proper receptacle. The disk sometimes in age obliterated the margin and becomes convex. The frond frequently consists of a mere crust adhering closely to the substance on which it grows, and scarcely separable from it. It becomes, however, by gentle degrees, foliaceous; and finally erect often branched bodies, as in the reindeer moss (*Cenomyce*) and cup moss, arise from the crust and bear the fruit. The order, in fact, contains some of the most obscure and some of the most beautiful of lichens. *Lecidea aurorum* is one of the most common examples of the crustaceous group, and is conspicuous from its golden hue, which is, however, far surpassed by that of *L. elegans*, which flourishes in extreme latitudes. [M. J. B.]

**LECYTHIDACEÆ. (Lecytha.)** A natural order of dicotyledonous plants, belonging to Lindley's myrtal alliance of epigynous Exogens. Large trees, with stipulate leaves and showy flowers, allied to *Myrtaceæ*, but distinguished by the large almond-like seeds, the alternate dotless leaves, and by the stamens being in part collected into a hooded plate. The fruit is a woody capsule, often opening by a lid. They are natives of the warm regions of South America. The seed-vessels are used as cups and bowls. The seeds of *Bertholletia excelsa* are the Brazil or Castanha nuts of the shops. There are about forty species distributed among seven genera. [J. H. B.]

**LECYTHIS.** A genus of *Lecythidaceæ*, almost exclusively confined to Venezuela, Guiana, and Brazil, where most of the thirty or forty known species attain a large size, their gigantic trunks towering to a height of eighty or more feet, and expanding into large heads of glossy foliage. The flowers have a six-lobed calyx, and six nearly equal petals, the centre being hid by the curious

hood-shaped body to which the sterile stamens are attached, and which serves to protect the fertile stamens seated beneath it. In most species the fruit is very hard and woody, and often of a large size; it is furnished with a lid at the top, which, when the fruit is quite ripe, falls away, and thus permits the escape of the seeds.

Under the name of Sapucala nuts, the seeds of *L. Zabucaya* are commonly sold in our fruit shops, and they will probably take the place of the closely-allied Brazil nuts, to which they are greatly superior in point of flavour and much easier of digestion. They are rather more than two inches long and one wide, covered with a longitudinally-furrowed corky shell, and grow in large hard woody fruits, shaped like urns, measuring about six inches in diameter, and having close-fitting lids at the top. Our supply comes from Parí, and is principally the produce of the Brazilian forests.

*L. Ollaria* is another species producing large fruits, commonly known as Monkey Pots, but its seeds are not so palatable as those of the last, leaving a bitter flavour in

*Lecythis Ollaria.*

the mouth. Its bark is composed of a great number (upwards of a hundred have been counted) of layers, not thicker than writing paper, which the Indians separate by beating, and employ, under the name of Tauré, for the wrappers of cigarettes. [A. B.]

**LEDEBOURIA.** A genus of milbous plants from India, referred to *Zillaceæ* by some authors, and to *Melanthaceæ* by others. They have broadly-lanceolate root-leaves, spotted like those of *Orchis maculata*, and scapes terminating in a raceme of bluish flowers, with a six-leaved bell-shaped deciduous perianth; six stamens with introrse anthers. The cells of the capsule are one-seeded. [J. T. S.]

**LEDGERIA.** *Cyrtosia*.

**LEDOCARPUM.** A genus of small Chilean shrubs belonging to *Orahidaceæ*. They have alternate, rarely opposite, three-parted leaves, with linear revolute segments, and rather large yellow terminal solitary flowers on long peduncles. The flowers have five sepals, with as many linear bracts on

the outside; five petals, ten free stamens, and a five-celled capsule. [J. T. S.]

**LÉDON, or LÉDE. (Fr.)** *Ledum*.

**LEDUM.** A genus of heathworts, having the calyx five-toothed, and the seed-capsule with five cells, each containing numerous small seeds, the outer coat of which is soft and forms a wing-like border at each end. The species are small shrubs, natives of the colder parts of the northern hemisphere; their leaves are of hard texture, usually with rust-coloured down on the lower surface. One of them, *L. palustre*, is known by the name of Labrador Tea, on account of its use. [G. D.]

**LEBA.** A genus of *Vitaceæ*, the type of the suborder *Leeæ*, distinguished by its petals being united at the base, by its monadelphous stamens, and by its three to six-celled ovaries, with the ovules solitary in each cell. The tendrils which are present in the true vines are absent in this suborder. They are rough shrubby plants (rarely trees) found in tropical Asia, Africa, and the Mauritius, and have opposite pinnate or bi-tri-pinnate leaves, and peduncles opposite the leaves, cymosely branched, with small greenish-yellow flowers, the petals united to the staminal cup, which is five-lobed, and has the five filaments adnate outside, between the lobes. [J. T. S.]

**LEE-CHEE, or LITCHI.** *Nephelium Litchi*.

**LEEK.** *Allium Porrum*. — **STONE.** *Allium fistulosum*. — **VINE.** *Allium Ampeloprasum*.

**LEERSIA.** A genus of grasses belonging to the tribe *Oryzææ*. Most of the species have the inflorescence in lax panicles; and the pales of the florets ribbed, thin, paper-like, of equal length, the outer somewhat boat-shaped. There are about a dozen species, which have an extensive range over some of the warmer parts of the globe; only one extends so far north as the British Isles, namely, *L. oryzoides*, which is found in wet ditches through the counties of Sussex, Surrey, and Hampshire, though it seldom flowers there. [D. M.]

**LEGNOTIDEÆ. (Cassipourææ.)** A tribe of *Rhizophoraceæ*, sometimes regarded as a distinct order. It consists of tropical trees or shrubs, with opposite entire stipulate leaves, and axillary solitary or clustered flowers, having the calyx bell-shaped, four to five-cleft; the petals four to five, fringed; and the stamens two or three times as many as the petals, distinct, with free filaments, and two-celled introrse anthers. The ovary is superior, three to five-celled; ovules two or more in each cell; style simple; stigma blunt. Fruit baccate or capsular. Lindley considers them to be allied to *L. paniculata*. *Cassipourea* is the principal genus. [J. H. B.]

**LEGUME.** The fruit of leguminous plants, as the pod of the pea; a solitary two-valved carpel, bearing its seeds on the ventral suture only.

**LEGUMINOSÆ. (Fabaceæ, Leguminosæ plants.)** A natural order of dicotyledons belonging to Lindley's roseal alliance of perigynous Exogens. Herbs, shrubs, or trees, with alternate usually compound stipulate leaves. Calyx five-parted, hypogynous, the odd segment inferior; petals usually five, sometimes one or more abortive, papilionaceous or regular, the odd petal superior; stamens definite or indefinite, perigynous, rarely hypogynous, distinct, or united in one or more bundles; ovary superior, one-celled, one or many-seeded, sometimes consisting of one carpel, sometimes of two or five; style and stigma simple. Fruit a legume or a drupe; seeds with or without albumen; embryo with large cotyledons.

This order is a large one, and the plants occur in all parts of the world, but are abundant in tropical countries. It has been divided into three suborders—1. *Papilionaceæ*: petals papilionaceous imbricate, upper one exterior; 2. *Cæsalpiniceæ*: petals imbricate, upper one interior; 3. *Mimoseæ*: petals valvate in aestivation. Some of the plants are nutritious, others tonic and astringent, others purgative, and a few poisonous. They supply timber, fibres, gums, dyes, and various economical substances. Amongst the useful plants of the order may be noted, beans, peas, lentils, kidneybeans, and pulse of various kinds, lupins, clover, lucerne, medick, sainfoin, liquorice, tragacanth, indigo, and kino. Among the poisonous plants are *Coronilla varia*, *Cytisus Laburnum*, *Gompholobium uncinatum*, and *Physostigma venenosum*, the ordeal bean of Calabar. There are about 550 genera and 7,000 species. Examples: *Lotus*, *Pisum*, *Vicia*, *Phaseolus*, *Cæsalpinia*, *Cassia*, *Acacia*. [J. H. B.]

**LEHMANNIA.** A Peruvian undershrub constituting a genus of *Solanaceæ*, or of *Atropaceæ* according to Miers. It has decurrent lance-shaped leaves, and racemes of dull purple flowers, the corollas of which are funnel-shaped with a short tube and a bell-shaped somewhat oblique plaited and five-toothed limb. By these latter characters the genus is distinguished from *Nicotiana*. [M. T. M.]

**LEIANTHUS.** A genus of *Gentianeæ*, very closely allied to *Lisianthus* and *Tuchia*. The points of distinction reside in the corolla which is regular; in the stamens which are bent downwards, and protrude beyond the corolla; and in the fruit which is one-celled, with the margins of the valves bent inwards. The leaves are opposite, and have sheathing connate stalks. The species are natives of the West Indies and Mexico. *L. nigrescens* has pendent purplish flowers, which in outward appearance are somewhat like those of *Atropa*. *L. limatiflorus* has yellow tubular flowers. Both are highly ornamental. [M. T. M.]

**LEICHARDTIA.** A genus of Australian *Asclepiadaceæ*, having a five-parted calyx, an urceolate corolla with the tube beardless within, and the throat with a thick-

ened ring, a five-lobed staminal crown, with the leaflets undivided, erect pollen-masses, and a scarcely divided stigma. *L. australis* is a climbing shrub, with linear acute leaves, and flowers in fascicles. [T. M.]

**LEIOCARPUS.** A genus of *Euphorbiaceae*, established by Blume for two Javanese shrubs referred to the tribe of *Buxus*; they are considered by Müller as belonging to the genus *Aronosa*; which see (Surr.)

**LEIOPHYLLUM.** A genus of *Eriaceae*, having a five-parted calyx; a corolla of five separate petals; ten exerted stamens; and a two to three-celled many-seeded pod, splitting from the apex downward. *L. buxifolium*, the only species, is a native of New Jersey, where it is called Sand Myrtle. [J. Br.]

**LEIOSPERMUM.** A genus of *Cunoniaceae*, allied to *Wemmannia*, differing in the deciduous calyx, and the flat (not urceolate) disk; the seeds also are glabrous, not hairy. They are New Zealand trees or shrubs, with opposite simple or pinnate leaves, having jointed leaf-stalks and enducous stipules; and the flowers are racemose. [J. T. S.]

**LEIOTHAMNUS.** A genus of *Gentianaceae*, represented by an Andean shrub, with opposite stalked leaves, axillary incurved flower-stalks provided with large bracts, a wingless calyx with five overlapping concave divisions, a salver-shaped deciduous corolla, its limb divided into five slightly unequal lobes, and five stamens inserted into a ring-like membrane, lining the base of the tube of the corolla, the anthers arrow-shaped, finally revolute. [M. T. M.]

**LEMATREA.** A genus of *Goodeniaceae*, proposed by De Vriese for an Ant plant, resembling a *Scaevola*, except that the style is said to be deprived of the indusium considered as characteristic of the order.

**LEMANEA.** A curious genus of green-spored *Algae* belonging to the natural group *Batrachospermum*, consisting of one or two species which grow mostly in sub-Alpine torrents. The first growth is precisely that of a conferva, but the walls of the frond at length become cellular, and are coated within with two or three layers of colourless cells, which give off tufts of necklace-like threads, the ultimate joints of which are the spores. It is, in point of structure, like a *Batrachospermum*, turned inside out. *L. funiculata* and *torulosa* occur not unfrequently in this country, the latter also in North America. [M. J. B.]

**LEMMAPHYLLUM.** *Drymoglossum*.

**LENNACEÆ.** A synonym of *Pistiaceæ*.

**LEMNA.** The Duckweed, the typical genus of *Pistiaceæ*. The species have a membranous urn-shaped spathe or flower sheath; flowers proceeding from immediately below the edge of the frond; stamens one to two; anthers two-celled. The plants float on water, and are propagated chiefly by buds. The 'green mantle of the standing pool' is

formed chiefly by *L. minor*. Four species are natives of Britain. [J. H. B.]

**LEMONIA.** A genus of *Rutaceae*, named in honour of Sir Charles Lemon, an enlightened patron of science and of horticulture. *L. spectabilis* is a Cuban shrub with ternate leaves, and axillary clusters of beautiful rose-coloured flowers, recognised by the following characters: calyx of five sepals, the two outer much larger than the three inner ones; corolla salver-shaped, with an oblique five-parted limb; stamens five, attached to the hairy inner surface of the corolla tube, two fertile sessile, three sterile, projecting from the tube, horned, glandular; ovary five-celled, surrounded by a lobed disk; stigma five-lobed. Fruit of five two-valved one-seeded carpels. It is often united with *Escentia*. [M. T. M.]

**LEMON.** The fruit of *Citrus Limonum*. There are many varieties, some of which bear the names of Citron, Cedrate, Genoa, or Wax Lemons. —, JAVA. *Citrus javanica*. —, MEDITAN. *Citrus Medica*. —, PEARL. A variety of *Citrus Limetta*. —, PEARL. *Citrus margarita*. —, SWEET. *Citrus Lumia*. —, WATERL. *Passiflora laurifolia*. —, WILD. *Podophyllum peltatum*.

**LEMON-COLOURED.** The purest yellow, without any brightness; as in a lemon when ripe.

**LENS-SHAPED.** The same as *Lenticular*.

**LENTIBULARIACEÆ.** (*Utriculariæ*, *Utriculariæ*, *Buttercups*.) A natural order of dicotyledons, belonging to Lindley's ligno-nal alliance of perigenous Exogones. Herbs growing in water or in wet places, with radical leaves, which are either undivided or cut into filiform root-like segments, bearing little bladders; and producing irregular showy flowers. Calyx divided, persistent; corolla bilabiate, irregular; stamens two, included, with one-celled anthers; ovary superior, one-celled, with a free central placenta. Fruit a one-celled capsule; seeds exalbuminous. Most abundant in the tropics. There are four genera, and about 180 species. *Pinguicula* and *Utricularia* are familiar examples. [J. H. B.]

**LENTICELLÆ** (adj. **LENTICELLATE**). Lenticular glands. Rudimentary roots appearing on the surface of the stems of many trees in the form of small conical swellings.

**LENTICULÆ.** The spore-cases of certain fungi.

**LENTICULAR, LENTIFORM.** Lens-shaped; resembling a double convex lens.

**LENTIGINOSE.** Covered with minute dots, as if dusted.

**LENTILS.** The seeds of *Ervum Lens*, from which *Revalenta Arabica* is prepared.

**LENTILE, or L. COMMUNE.** (Fr.) *Ervum Lens*. —, DEAN. *Lemna minor*. —, DESPAGNE. *Lathyrus sativus*.

**LENTILLON.** (Fr.) *Ervum Lens minor*.

**LENTINUS.** A large genus of gill-bearing *Fungi*, distinguished principally from *Agaricus* by their tough substance, and from *Panus* by their thin toothed gills. Two or three species are found in this country, and a few more in Europe and North America, the maximum being attained in hot countries, where they are the ornaments of the woods from their beautiful forms, elegant sculpture, and various clothing. The tough substance renders them unfit for food, but easy of preservation, so that more is known of them than of most tropical *Agaricini*, as they are brought home by every collector, when the more watery and fleshy species are neglected. [M. J. B.]

**LENTISCUS.** *Pistacia Lentiscus*.

**LENTISQUE** (Fr.) *Pistacia Lentiscus*.

**LENZITES.** A genus of gill-bearing *Fungi*, distinguished from *Agaricus* by its tough corky substance and gills. It leads in fact directly through *Dedalea* to the pore-bearing *Fungi*, the gills in certain states being so connected with transverse processes as almost to constitute pores. *L. betulina* is our commonest species, and is often very beautiful from the purity of its hymenium, and the zoned velvety pileus. It occurs on stumps of various trees, and on wrought wood. *L. scoparia* is often very rich in colouring, showing various tints of brown and reddish-yellow. It is sometimes abundant on imported deals, but is scarcely indigenous. [M. J. B.]

**LEOCHILUS.** A genus of South American epiphytes of the orchid family, allied to *Oncidium*, from which it is distinguished by the arms of the column being placed below the stigma, and by the presence of a honey-pore at the base of the lip. The species, which are not numerous, are pseudo-bulbous, and produce small, often yellowish flowers in racemes. [T. M.]

**LEONIA.** This genus, referred by Mr. Benthani to the *Violaceae*, consists of two species, one found in Peru, the other in Brazil. They form moderately high trees, and have alternate entire leaves, full of pellucid dots, with small deciduous stipules at their base. The flowers are small, full of dots, with a five-parted calyx of round fringed lobes; five petals slightly cohering, but ultimately free; and four stamens, with their filaments united into a short tube. *L. glycyarpa* produces edible fruit, greatly relished by the Peruvians, who call the tree Achoron. It is of a roundish form, about the size of a peach, with a rough yellow rind, marked with a kind of network, and contains from six to ten seeds, and a soft whitish pulp or flesh possessing an agreeable sweet taste. [A. S.]

**LEONOTIS.** A genus of herbaceous or somewhat shrubby plants belonging to the *Labiatae*, well distinguished among its congeners by the elongated concave entire upper lip of the corolla, and the very short lower lip which is nearly equally three-cleft.

The species inhabit the southern hemisphere, and are cultivated in English conservatories for the sake of their handsome orange flowers, which grow in dense whorls, with numerous very narrow bracts. The Greek name *Leonotis* (or Lion's ear) was given from some fancied resemblance of the corolla to a lion's ear. One species, *L. Leonurus*, a native of the Cape of Good Hope, received its second systematic, and its popular name Lion's tail, from the assumed resemblance of the inflorescence to a lion's tail, an infelicitous combination of not very apposite terms. French, *Queue de lion*; German, *Löwenschwanz*. [C. A. J.]

**LEONTICE.** A small genus of *Berberidaceae*, of Southern and Eastern Europe, and Western and Northern Asia, consisting of smooth herbaceous plants with tuberous roots, which annually send up several variously-cut leaves, and stems about a foot or a foot and a half high, bearing smaller leaves, and racemes of small yellow flowers. The only one consists of six coloured sepals; the corolla of six smaller stalked petals, bearing scales at the bottom on the inside. The fruits are inflated or bladder-like, of a thin texture, marked with netted veins. *L. Leontopetalum* is a strong-growing herbaceous plant, having large long-stalked leaves, composed of six inversely egg-shaped stalked leaflets arranged in threes. It is commonly called Lion's leaf, on account of a fancied resemblance between the leaves and the imprint of a lion's foot. Its tuberous roots, sometimes called Lion's turnips, are pounded and used at Aleppo, instead of soap, for washing woollen garments, and more particularly for taking out spots or stains from Cashmere shawls. Medicinal properties were formerly ascribed to them, Dioscorides attributing to them the power of allaying the pain caused by snake bites; and the Turks of the present day employ them as an antidote to the effects of overdoses of opium. [A. S.]

**LEONTODON.** A genus of *Compositae*, having a perennial rootstock, from which proceed, near to the ground, a number of spreading toothed leaves. The flower-stalks are usually leafless, the flowers yellow, all strap-shaped, surrounded by several rows of overlapping bracts, but the receptacle on which the flowers are immediately placed is destitute of bracts. The fruits taper above into a short beak, and are surmounted by a pappus of feathery hairs, which latter circumstance serves to separate the genus from the nearly-allied *Taraxacum*. The species are widely spread over Europe and central Asia. Three of them, according to Mr. Benthani, are British, viz. *L. hispidus*, *autumnalis* (formerly ranged under *Apargia*), and *hirtus* (which has been also called *Thrinacia*). *L. hispidus* is covered with short hairs that are frequently stellate. [M. T. M.]

**LEONTOPODIUM.** A genus established by Cassini and adopted by De Candolle for the *Gnaphalium Leontopodium* from the Alps of Europe, and two closely-allied species of

varieties from the mountains of Asia, which differ slightly in the pappus from other species. They are also remarkable for their dense clusters of flower-heads surrounded by a kind of radiating general involucre of floral leaves, all densely clothed with a close white cotton.

**LEONURUS.** A small genus of *Labiatae*, consisting of erect herbs, with the leaves more or less lobed, and the small flowers in close axillary verticillasters, forming long leafy spikes. The calyx has five prominent ribs and five equal spreading almost prickly teeth; the corolla has a shortish tube, a concave entire upper lip, and a spreading three-lobed lower one; the stamens form two pairs; and the nuts are flat, angular at top. *L. Cordacea*, or Motherwort, is found in wastes, hedges, &c., in Europe and Russian Asia, and has pinkish flowers with a very hairy upper lip. The genus is allied to *Stachys*, differing chiefly in the shape of the nuts. [T. M.]

**LEOPARD'S BANE.** *Doronicum*; also *Scorpio Doronicum*, *Aronicum Clusi*, and *Puls quadrifida*.

**LEOPARD WOOD.** The wood of *Bromum tabebu*, also said to be applied to a fancy wood of the palm tribe.

**LEOPOLDINIA.** A small genus of Brazilian palms, comprising three or four species, existing in considerable numbers on the Amazon and Rio Negro, and forming trees of medium size bearing terminal unarmed pinnate leaves, and having the upper part of their stems covered with a copious network of fibres. Their flower-spikes are very much branched, with two small spathe-like, the male flowers being seated on the upper, and the female on the lower part of the spike.

*L. Pissaba* is one of the palms which yield the Pissaba or Pucaba fibre, now so extensively employed in this country by its natives, and also for making the stout street brooms used in most large cities. Two distinct varieties of this fibre are recognised in commerce, one a coarse kind obtained from *Attalea juazeira* and imported from Bahia; and the other a finer kind brought from Para, and the produce of the *Leopoldinia*, which is found growing in great abundance on the extensive plains between the Rio Negro and Orinoco rivers, forming entire forests. It attains a height of fifteen or twenty, or occasionally as much as forty feet, and the fibre or beard, as it is usually called, which is the envelope of the young leaves, hangs down all round and completely covers the trunk quite to the ground, except in very tall trees, the lower part of whose trunk is generally bare. [A. S.]

**LEOTIA.** A genus of the helvellaceous order of pyrenomycetous *Fungi*, distinguished by its gelatinous substance, and the button-shaped head, the borders of which are rounded and confluent below with the stem. *L. lubrica* is a common in-

habitant of our woods, and varies in tint from dull yellow to olive. [M. J. B.]

**LEPALS.** Sterile stamens.

**LEPANTHES.** A genus of minute-flowered West Indian orchids, closely related to *Pleurothallis*. [T. M.]

**LEPICYSTIS.** *Goniophlebium*.

**LEPIDADENIA.** A genus of *Lauraceae*, represented by an Indian tree, with ribbed leaves, and hermaphrodite flowers in umbels surrounded by an involucre. The perianth has six nearly equal segments; stamens twelve in four rows, the two inner surrounded by scales, whence the name; anthers four-celled, four-valved. [M. T. M.]

**LEPIDANCHE.** A proposed genus of *Cuscutaceae*, but generally accepted as a section of *Cuscuta*, including those species which have five sepals in the calyx, a sub-tubulose urceolate corolla, a two-celled ovary always with two styles, and a two-celled capsule with no more than one seed in each cell. [W. C.]

**LEPIDANTHUS.** A genus of *Brassicaceae* from the Cape of Good Hope, with simple leafless stems, and spicate terminal male flowers, which have three glumes, and three stamens. [J. T. E.]

**LEPIDES** (adj. **LEPIDOTE**). Scurfy; minute petiole scales, such as cover the foliage of *Elaeagnus*.

**LEPIDIDIUM.** The Cresses form a very extensive genus of *Brassicaceae* (*Cruciferae*) widely spread throughout the temperate regions of the earth, but abounding in the greatest number in the northern hemisphere. They are annual or perennial herbs, occasionally with woody stems, and have entire or variously cut leaves, and numerous small white flowers arranged in terminal racemes, which grow longer while fruiting. The genus is distinguished from its congeners by characters taken from its pods, which are egg-shaped or oblong, entire, notched or two-lobed at the apex, and compressed at right angles to the narrow partition dividing them into two boat-shaped valves.

*L. oleraceum* is confined to New Zealand, where it is found growing abundantly upon the sea-shores, and, being a good antiscorbutic, it was eagerly sought after by early voyagers as a remedy for the dreadful scurvy with which their crews were so frequently affected. The natives call it Eke-tera; and it is now cultivated as a pot herb. It is a smooth erectish branching plant, with a short woody stem and narrow-oblong or wedge-shaped leaves, two or three inches long, the lower ones being sharply serrated, and the upper entire or toothed towards the tip. The natives of the Society and Sandwich Islands make use of *L. Pseudium* for catching fish, it, in common with several other plants, possessing the property of intoxicating them so that they float upon the surface in a helpless insensible state, and are then easily taken. The

whole plant possesses an extremely pungent taste. [A. S.]

*L. sativum*, the Garden Cress, is a hardy annual whose native country is stated to be Persia. It has been cultivated in this country since 1548, and is a comparatively dwarf uninteresting plant, having oblong alternate deeply-divided leaves, smooth erect branching stems, and small white flowers producing an orbicular winged seed-pod. The chief purpose for which it is grown in gardens is for its leaves, which are cut and used in a young state with those of mustard for salads, to which it gives a peculiarly warm and grateful flavour. It is on this account very generally cultivated and esteemed as one of the most useful plants for small salads that we possess. The leaves when full grown are frequently employed for garnishing like those of parsley. [W. B. B.]

**LEPIDOCARYUM.** A genus of palms containing two species found in moist places in forests on the banks of the Rio Negro in Brazil. Both have slender stems of ten or twelve feet high, the upper part being covered with remnants of the stalks of dead leaves, and bearing at the summit a tuft of fern-shaped irregularly-cleft leaves with bristly margins. They have perfect and imperfect flowers; and their flower-spike consists of numerous little catkins proceeding from sheathing spathe at short intervals along its branches; the male catkins being longer than those of the female, and having their flowers in pairs within cup-shaped bracts, while in the latter they are solitary. Their fruits are of a reddish-brown colour and vary from the size of a hazel-nut to that of a pigeon's egg, and, like those of other palms belonging to the same section (*Culamee*), are covered with hard scales arranged like plates of mail in ancient armour. Neither of the species (*L. gracile* and *L. tenuis*) possesses any special feature of interest. [A. S.]

**LEPIDONEURON.** *Nephrolepis*.

**LEPIDOSTACHYS.** A genus of East Indian *Euphorbiaceae*, which proves to be the same as *Scopa* of Lindley, *Aporosa* of Blume.

**LEPIDOSTEPHANUS.** *Achyrochama*.

**LEPIDOTIS.** *Lycopodium*.

**LEPIGONUM.** *Spergularia*.

**LEPINGIA permariorum** is a procumbent branching Californian annual, forming a genus of *Compositae*, which has the aspect of an *Asterum* with the style of one of the *Senecionidae*. The lower leaves are pinnatifid, the upper ones entire, the flower-heads yellow, not showy, either terminal or lateral, without rays. The involucre is imbricated, the receptacle naked, the achenes silky, with a bristly pappus.

**LEPIOTA.** A subgenus of *Agaricus*, characterized by the free white-spored gills, and well-formed ring. *Agaricus procerus*, one of our best esculent fungi, and very ornamental, belongs to this subgenus. [M. J. B.]

**LEPISANTHES.** A genus proposed by Blume for two or three East Indian trees which may be better considered as forming a subgenus or section of *Cupania*.

**LEPISMA.** A cup-shaped disk.

**LEPISIUM.** A small genus of *Cactaceae* now regarded as a section of *Rhipsalis*, but at one time separated, and characterized by the petal-like leaves of its perianth standing almost erect, while those of *Rhipsalis* are widely expanded; and by its smooth pear-shaped fruits being somewhat buried in the fleshy substance of the branches. The three or four known species are natives of Brazil. They have weak, fleshy, jointed branches, occasionally emitting roots, the joints being sharply three or four-angled, waved along the edges, and bearing tufts of hairs seated upon little cushions in the depressions from out of which the small cream-coloured flowers are produced. *L. communis* and *L. Myosurus* are cultivated in European gardens. [A. S.]

**LEPISTEMON.** A genus of *Convolvulaceae*, containing two species, natives of India and the islands of the Indian Archipelago. They are twining hairy shrubs, with many-flowered axillary peduncles. The calyx consists of five equal sepals; the corolla is tubular and inflated at the base; the five stamens spring from the back of as many large arched hairy scales which are united to the base of the corolla; the ovary is two-celled with two ovules in each cell, and bears a stigma composed of two capitate lobes. [W. C.]

**LEPISTOMA javanicum**, is a twining shrub, with elliptical oblong leaves, and interpetiolar peduncles, growing in the island of Java, and representing a genus of *Asclepiadaceae*. The calyx is turbinate and has five teeth; the corolla is rotate and five-cleft; whilst the fruit is unknown. Uses not recorded. [B. S.]

**LEPRA** (adj. **LEPROUS**). A white mealy matter, which exudes or protrudes from the surface of some plants; leprosy.

**LEPRARIA.** An abnormal condition of certain lichens in which the crust is broken up into a dusty mass, occasionally mixed with a few threads. The yellow powdery and white patches which are so common on oak are examples, the one being a condition of some lichen like *Parmelia parietina*, and the latter of *Porina pertusa*. The genus is now, however, justly exploded. [M. J. B.]

**LEPROSE.** Having a scurfy appearance.

**LEPTADENIA.** A genus of *Asclepiadaceae*, inhabiting tropical and subtropical parts of Africa and Asia, and comprising erect leafless shrubs, or twiners furnished with leaves. There are about a dozen species described, all having a greyish tomentum covering stem and leaves. The flowers are white, small, and arranged in interpetiolar umbels. The calyx is short,

the corolla rotate or bell-shaped, the fruit quite smooth on the surface. [B. S.]

**LEPTANDRA.** *Veronica*.

**LEPTANTHUS.** A small genus of aquatic herbs belonging to the *Pontederiacae*, natives of North America, differing from *Heliconia* in having the three filaments all alike. *L. graminea* is common in streams in North America, and has much the habit of the narrow-leaved pond-weeds. The small yellow flowers with a salver-shaped perianth float on the surface of the water, and are produced from a one-flowered terminal spathe. [J. T. S.]

**LEPTARRHENA.** A genus of *Saxifragaceae*, found on the north-west coast of America, and in Kamtschatka. It is allied to *Saxifraga*, from which it differs by the anthers being four-celled (the partition being incomplete), and by the two carpels adhering only by their bases: a herb with shining evergreen leathery undivided and serrate leaves, resembling those of *Pyrola secunda*; scape with a terminal panicle of small inconspicuous white flowers. [J. T. S.]

**LEPTINELLA.** A genus of *Compositae* of the tribe *Anthemideae*, consisting of four or five prostrate or procumbent herbs with the scent of *Artemisia* or of tansy, all natives of the southern extremity of South America, or of some of the Antarctic islands. They are remarkable for the shape of the minute ray-florets, of which the corolla appears to be formed by a double membrane connected at the summit and the base, with a cavity between them. One species, *L. scariosa*, though possessed of no beauty, is interesting as one of the flowering plants which extend the furthest into the Antarctic regions.

**LEPTOCARPUS.** A genus of Australian *Rutaceae*, consisting of leafless herbs, with the stems simple, and the dimerous flowers fasciculate. [J. T. S.]

**LEPTOCAULIS.** A genus of umbellifers, characterised by each half of the fruit having five inconspicuous ribs, and one oil-vessel (vitta) in each furrow. The species are natives of North America, of no great interest, having umbels of few small white flowers. [G. D.]

**LEPTOCERAS.** A genus of terrestrial Australian orchids belonging to the *Arethuseae*. They have solitary or geminate radical leaves, and one or many-flowered scapes, the flowers often fragrant. They have membranaceous sepals, the upper fornicate, the lateral deflexed; clavate erect petals; a lip articulated with the winged column; and four pollen-masses. [T. M.]

**LEPTOCHILUS.** *Gymnopteria*.

**LEPTOCHLOA.** A genus of grasses belonging to the tribe *Chlorideae*. The spikes of inflorescence are disposed in racemes, and the spikelets mostly unilateral, two or more-flowered; glumes keeled; outer pale keeled, three-nerved, with a straight awn.

The species, of which about three dozen are described, are, for the most part, handsome grasses, and chiefly natives of South America and the West Indies. *L. arubica* is found growing near Naples. [D. M.]

**LEPTODACTYLON.** A section of *Gilia*, originally proposed as a distinct genus of *Polemoniaceae*. The three species are distinguished from other *Gilias* by the following characteristics: they are lowly branching perennial herbs, with alternate sessile palmatisect leaves, the segments subulate and needle-like; and the solitary sessile flowers are either terminal or axillary at the tops of the branches; the divisions of the calyx are subulate and prickly; the corolla is somewhat salver-shaped, with entire lobes; the anthers are ovate; and there are many ovules in each cell of the ovary. Natives of North America. [W. G.]

**LEPTODAPHNE.** A genus of Brazilian lauraceous trees, with net-veined leaves, and flowers in panicles. The perianth is funnel-shaped, with a limb of six deciduous segments; stamens nine, in three rows, the outer six fertile, some of them provided with an erect tooth-like appendage; the inner three sterile, sometimes absent, and when present having two glands at their base; the anthers are four-celled. The fruit is fleshy and enclosed within the fleshy base of the perianth. [M. T. M.]

**LEPTOGLOSSIS.** A genus of Peruvian herbaceous plants of the family *Scrophulariaceae*. The leaves are hairy; and the flowers grow at the extremity of the branches, the corolla limb being somewhat two lipped. The genus is intermediate between *Schrenkia* and *Browallia*. [M. T. M.]

**LEPTOGRAMMA.** *Grammitis*.

**LEPTOLÆNA multiflora** is the sole representative of a genus of *Chenopacea*, inhabiting Madagascar. It is an elegant tree, bearing undulate glabrous leaves, corymbose flowers, with a fleshy cylindrical involucre, three sepals, five petals, and ten stamens; and a three-celled capsule, with one or two seeds in each cell. [B. S.]

**LEPTOLOBIUM.** This name has been applied to two genera of *Leguminosae*, but is now abandoned. The species so named by Vogel are Brazilian trees now referred to *Butea* (see *ECPL.*) in *Sophorae*, and distinguished by the lobes of the calyx equalling or exceeding the tube. Benthams gave the name to a few Australian and Asiatic plants of the tribe *Phaseoleae*, and which was afterwards changed by him to *Leptogrammus*; they are now united with *Glycyne*, from which they differ only in the flowers being distinct from each other, not clustered along the rachis of the raceme. [J. Br.]

**LEPTOMERIA.** An Australian genus of *Santalaceae*, abounding in the neighbourhood of Swan River. About twenty species are known, two of them separated by some botanists under the name of *Omphalomeria*. They are broom-like shrubs, with angular or roundish twiggy branches, gene-

rally entirely destitute of leaves, or with very small ones only upon the young twigs, and bearing spikes of extremely minute flowers. The fruit is either fleshy and juicy or dry and juiceless, and has a scar at the top surrounded by the remains of the calyx. *L. Billardieri* is a pretty broom-like shrub, growing about six feet high, with erect very slender branches, and numerous spikes of small white flowers producing greenish-red berries, which are called Native Currants in New South Wales and Victoria; they have a pleasant acid taste, combined with a certain degree of astringency. Mixed with other fruits, they are used for making preserves, and in the preparation of cooling acid beverages. The fruit of another species, *L. (Omphacomeria) acerba*, is also called Currants in Australia, and is used for the same purposes. [A. S.]

**LEPTONEMA.** A low branching Madagascarian shrub, with the habit of a *Vaccinium*, but constituting a genus of *Euphorbiaceae*, of the tribe *Phyllanthæ*. Dr. Mueller has since referred to the same genus, as a second species, a shrub from tropical Australia.

**LEPTOPETALUM.** This name, signifying slender or narrow petal, is applied to a Mexican shrub constituting a genus of *Cinchonaceae*. The flowers are in terminal corymbs, and have a somewhat globular calyx tube, with a four-toothed limb; the corolla is divided into four long very narrow segments; stamens four, equalling the corolla; capsule hemispherical, crowned by the teeth of the calyx, and opening by a chink at the top; seeds small, angular. [M. T. M.]

**LEPTOPTERIS.** A Sumatra plant, proposed by Blume as a distinct genus, but which appears to be the same as the *Medicla* of Gardner, a species of *Gelsemium*.

The name is also sometimes unnecessarily given to those species of *Todea* which have delicate membranaceous fronds and oligocarpous sori. [T. M.]

**LEPTOPUR.** An East Indian herb proposed by Decaisne as a genus of *Euphorbiaceae*, but reduced by Baillon to *Andrachne*.

**LEPTORHACHIS.** A genus of *Euphorbiaceae* of the tribe *Acalyphæ*, founded by Klotzsch on a Brazilian herbaceous twiner with hastate leaves, and having the habit of a *Trapa*. [J. Br.]

**LEPTORHYNCHUS.** A genus of *Compositæ* allied to *Helichrysum*, but the florets are all hermaphrodite, and the achenes are narrowed into a slender beak bearing a pappus of simple bristles. There are several species, natives of Australia, all erect herbs with narrow leaves and terminal flower-heads of yellow florets, not so handsome as other everlastings, the involucres being smaller and less scarious.

**LEPTOS.** In Greek compounds = slender, graceful; as *leptophyllus*, slender-leaved.

**LEPTOSEMA.** A North Australian papilionaceous shrub, proposed by Benthham as a genus of *Leguminosæ*, which has since been reduced to *Brachysema*.

**LEPTOSIPHON.** A name applied to some Californian annuals, which are now generally considered as forming a section of *Guiz.* which see. [J. Br.]

**LEPTOSOLENA.** A genus of *Singiberaceæ*, closely related to *Alysicum* and *Renealmia*, and containing but one species, *L. Bankoi*, native of the island of Luzon. It has an erect leafy stem, with oblong acuminate leaves terminated by a sessile branched panicle of flowers with bracts at its base. The tube of the corolla is elongate and filiform, the outer segments spreading, the inner segments very short. [J. Br.]

**LEPTOSPERMUM.** A large genus of shrubs or small trees belonging to the *Myrtaceæ*, and nearly all confined to Australia and Tasmania. The leaves are alternate, small, leathery, and full of dots or cells containing oil; and their white flowers are borne on short stalks on the sides of the young branches, either solitary or in little clusters. They have a bell-shaped calyx with five lobes; a corolla of five roundish petals; numerous short free stamens; and a four or five-celled ovary. *L. taugerum*, a native of Tasmania and South-eastern Australia, is commonly called Tea tree on account of its leaves having been used by the early settlers in those countries as a substitute for tea. It sometimes forms a tree thirty feet high, with a trunk four or five feet in circumference, but in mountainous situations is only a small shrub a few feet in height. Its straight stems were used by the Australian aborigines for making their spears, the points being sharpened with a flint and then hardened by means of fire. *L. scoparium*, the Kahi-Katon or Manuka of the New Zealanders, a shrub of moderate height, with harsh prickly leaves, produces a very hard heavy wood, but its small size renders it of little value. [A. S.]

**LEPTOSTACHYA.** A genus of *Acanthaceæ*, containing seventeen species chiefly natives of America and India. They are herbs, rarely shrubs, with opposite leaves, and distant opposite flowers in slender terminal or axillary spikes, furnished with many small bracts and bracteoles. The small calyx is five-parted; the corolla ringent with a longish tube and a two-lipped limb, the upper lip arching and two-toothed, the lower convex and trifid; two stamens are inserted in the tube; and the ovary is two-celled surmounted by a simple style and trifid stigma. This genus is less distinct from its technical character than from its habit and inflorescence. [W. C.]

**LEPTOSTEGIA.** *Onychium*.

**LEPTOSTELMA.** The Mexican Daisy (*Erigeron maximus*) is sometimes cultivated under this name. It attains a height of five to seven feet, and is rather hand-

some when in flower. The whole plant is more or less clothed with short stiff hairs; the lower leaves, a foot long, lanceolate and coarsely toothed, the upper amplexicaul; the flower-heads more than an inch across, the ray-florets strap-shaped, purple, and very narrow. [A. A. B.]

**LEPTOTICHUS.** Thin-skinned; a term applied only to tissue.

**LEPTOTES.** A small genus of Brazilian orchids of the tribe *Epidendreae*, distinguished by having the sepals and petals linear spreading and nearly equal; the lip three-lobed, parallel with the short thick column, around which the lateral lobes are convolute; the six pollen-masses incumbent, the two upper ones pear-shaped, the four lower ones unequal and thinner. *L. bicolor*, a pretty epiphyte with thick rush-like leaves, and white flowers blotched on the lip with purple, bears fragrant fruit with the odour of the Tonquin bean or of the sweet vernal grass. This fruit infused in cream gives it, when fed, a mild agreeable flavour, sweeter than vanilla but less penetrating. *L. serrulata* is a second species with larger flowers. [T. M.]

**LEPTURUS.** A genus of grasses belonging to the tribe *Rotthelieae*. The inflorescence is mostly in close round solitary spikelets, imbedded alternately on opposite sides of the rachis; glumes one or two, thick, on the same side of the spikelet, which contains one perfect floret, and the rudiment only of a second floret. The species are mostly natives of the north-east of Europe and New Holland. *L. incurvatus* extends to the British Isles, and grows on most of the salt marshes along the seaboard, where it often furnishes the principal pasture grass. [D. M.]

**LEPURANDRA.** The Sack-tree of Western India, a tree of the *Artocarpaceae*, now referred to *Antiaris* and called *A. saccidora*, has been so called. It is a gigantic tree, reaching a height of a hundred feet, with a trunk six feet in diameter, exuding a milky juice when wounded, and having a strong tough fibrous inner bark useful for the manufacture of cordage, and of which the natives, by an ingenious yet simple process, make capital sacks. For this purpose young trees of about a foot in diameter are selected, and cut intounks of the same length as the sack required. These are then soaked for a short time and afterwards beaten with clubs until the outer bark is removed and the inner loosened so that it can readily be separated by turning it inside out. Sometimes a small piece of the wood is left to form the bottom of the sack, but more frequently the bark is pulled entirely off and the bottom sewed up. These sacks are commonly used by the natives of Western India and of Ceylon for carrying rice, &c., and are very strong and elastic. A considerable quantity of milky viscid juice exudes from the fruit when wounded, and hardens into the appearance and consistence of bees' wax, but eventually becomes

black and shining; the seeds have an intensely bitter taste. [A. B.]

**LEPYRODIA.** A genus of Australian *Bastaceae* with simple leafless stems, and compound spikes of dioecious, or rarely simple spikes of perfect flowers. [J. T. S.]

**LEQUÉE.** (Fr.) *Lechea*.

**LERENA.** A species of *Rajania*, whose roots are used in St. Domingo like potatoes, and are said to be extremely nutritive.

**LERIA.** A genus of *Compositae* of the tribe *Mutiseae*, consisting of South American perennials, with the leaves all radical and white cottony underneath, and solitary flower-heads on long simple cottony scapes. The inner disk florets are obscurely bilabiate, while the outer radiating ones pass into ligules without any inner lip. The pappus consists of numerous simple bristles. There are about half a dozen species known, none of them in cultivation.

**LESCHENAUTIA.** A genus of goodeniaceous heath-like shrubs, distinguished by having a tubular calyx with five linear sharp-pointed lobes and a partially two-lipped corolla, the tube of which is split on its upper side. The anthers cohere previous to the opening of the flowers, which are axillary or terminal, of a red, blue, or yellow colour. The leaves are linear and sharp-pointed. The plants are natives of the south and south-west parts of Australia, and are very ornamental. [R. H.]

**LESKEA.** A genus of pleurocarpous mosses, distinguished from *Hypnum* by its erect more or less symmetrical capsule, and the want in general of intermediate cilia. The limits are not, however, very acutely marked. Our commonest species, *L. sericea*, grows on almost every ash tree, forming silky yellowish-green patches, which are darker when dry, and add much to the picturesque effect of the bark. There are many exotic species. [M. J. B.]

**LESSERTIA.** A genus of *Leguminosae* of the suborder *Papilionaceae*, consisting of herbs or undershrubs with pinnate leaves, and pink or crimson, rarely white flowers in axillary racemes. There are above thirty species described, all from the Cape Colony. They much resemble the Australian *Swainsonia*, both in habit and character, differing chiefly in the pod, which, though membranous as in *Swainsonia*, is perfectly flat, and never inflated. None of the species are in cultivation, and few are so showy as those of *Swainsonia*.

**LESSINGIA.** A genus of Californian *Compositae* consisting of procumbent branched herbs, with thickish leaves, the lower ones pinnatifid, and yellow solitary terminal flower-heads, with an imbricated involucre and naked receptacle, the florets all tubulose, those of the ray larger than the rest. The achenes are silky and compressed, with a pappus of one row, the hairs rigid and scabrous. [T. M.]

**LESSONIA.** A genus of seaweeds be-

longing to the natural order *Laminariaceae*, with a tall thick stem, branched above and bearing at each tip a pair of lanceolate leaves which hang down for a foot or more in length. The species form large submarine forests, and the stems when thrown ashore look like wood; hence they are sometimes collected by seamen for firewood, to their great disappointment when they attempt to use them. They are employed more profitably for knife handles, and other similar purposes. The blade is fixed in when the plant is moist, and is effectually fastened by its contraction when dry. The stems have a kind of false exogenous growth, of which a representation may be seen in *Berkeley's Introduction to Cryptogamic Botany*, p. 56. The new rings seem to depend upon the growth of the leaves, whereas in the large *Laminariæ* where a similar structure occurs, it depends upon the development of new roots or holdfasts. *Lessonia* are principally at home in the southern hemisphere. [M. J. B.]

**LETHARGIA.** A name applied in vegetable pathology to those cases in which the buds of transplanted plants and grafts, or the embryos of seeds, though still possessed of vitality, are sluggish and other are not developed at all, or are expanded imperfectly. Close pruning is often necessary to overcome this evil in plants which are not removed till spring; and artificial means, as the application of hot water, weak solutions of acids, &c., are sometimes needful to overcome the suspended animation of seeds. Some roots, again, like those of orchids, occasionally lie dormant in the soil for years, where they are excluded from the light by an overgrowth of shrubs. *Ophrys muscifera* and some other species in certain districts appear only after the underwood has been cut down. Portions of the tubers of dahlias, again, if no part of the crown be left, will live for years without throwing out a single bud. [M. J. B.]

**LETTERED.** Bearing letter-like spots.

**LETTER-LEAF or LETTER-PLANT.** *Grammatophyllum*.

**LETTER-WOOD.** *Brontium Aubletii*, sometimes called *Pissinera guianensis*.

**LETTOMIA.** A name given by Ruiz and Pavon to a genus of *Ternstroemiaceæ*, since united with *Freziera*; and by Roxburgh to a convolvulaceous genus which has proved to be identical with *Argyrea*.

**LETTUCE.** *Lactuca*. —, **BLUE.** *Mulgedium*. —, **CABBAGE.** Garden lettuces with low depressed cabbage-like hearts. —, **COS.** The erect-growing crisp-leaved varieties of garden lettuce. —, **FALSE.** *Mulgedium*. —, **GARDEN.** *Lactuca sativa*. —, **LAMB'S.** *Valerianella oleracea*. —, **PRICKLY.** *Lactuca Scariola*. —, **SEA.** *Fucus vesiculosus*. —, **WILD.** *Lactuca virga*.

**LETTUCE TREE.** *Pisonia morindifolia*, common in gardens in S. and W. India.

**LEUCANDERON.** A genus of proteaceous plants, mostly shrubs or small trees, natives of the Cape of Good Hope and the

south-eastern parts of Africa, distinguished by having the calyx either four-cleft or with four sepals, each of which bears a nearly sessile anther, and a filiform style with an oblique club-shaped stigma. The seed-vase is one-celled, containing a single wingless seed. The involucre is generally imbricated; the dioecious flowers (white or yellow) are produced in small heads; and the leaves are generally sessile, simple, entire, occasionally covered with white silky hairs. *L. argenteum*, the Witteboom or Silver tree of the Cape colonists, was formerly of great importance for firewood, but it is now nearly extirpated. [R. H.]

**LEUCENA.** A genus of *Leguminosæ*, of the suborder *Mimosæ*, characterised by having the ten stamens of a *Mimosa*, with the flat two-valved pod of an *Acacia*. It consists of eight species, trees or shrubs, all natives of central or South America, or the Pacific Islands, with twice-pinnate leaves, and small white flowers in globular heads. One species, *L. glauca*, is much cultivated as an ornamental tree in most warm climates, and has become naturalised and apparently wild in several parts of Africa and Asia. In Europe it will bear the winter only in the warmer parts of the Mediterranean region, where it is occasionally planted.

**LEUCANTHEMUM.** A name given to the Ox-eye Daisy, *Chrysanthemum Leucanthemum*, and a few other species, which have been distinguished from other *Chrysanthemums* as a genus on account of some very slight differences in the achenes.

**LEUCAS.** A genus of *Labiatæ*, having the upper lip of the corolla concave, usually entire and hairy on the outside, the lower lip spreading, its middle lobe largest; having also the end of the style of two unequal pieces, the upper of which is shortest. They are herbs or shrubs, natives chiefly of tropical Asia and Africa. The flowers are white, rarely purple. [G. D.]

**LEUCERIA.** A genus of *Compositæ* of the suborder *Mutisaceæ*, consisting of eight or nine Chilian herbs, with erect or ascending stems, more or less clothed with white cottony wool. The leaves are mostly pinnately divided, cottony underneath, the flower-heads small in terminal panicles. The involucre is hemispherical and imbricate, the outer florets radiating; the pappus consists of shortly plumose bristles. None of the species offer any particular interest either as useful or ornamental plants.

**LEUCHTENBERGIA.** A remarkable genus of *Cactaceæ*, of which the only species, *L. principis*, a native of Southern Mexico, has been introduced to European gardens. In this plant the mammille, as the variously-shaped projections seen in most *Cacti* are called, grow very long, and being of a succulent nature and three-sided shape, they somewhat resemble aloe leaves, but bear tufts of long chaffy or horny scales on their apex. The plant itself grows a foot or more high, the lower part of the stem being about as thick as a man's arm, hard and

woody, and covered with the remains of decayed mamillæ, while the upper bears long perfect mamillæ, and looks very much like an artichoke. The flowers, which are produced at the top of the plant among the younger mamillæ, bear a great resemblance to those of *Cereus*, but are distinguished by the tube of their perianth being more cylindrical, and having the stamens growing to its inside as far as the bottom of the petals, after which they converge and meet in the centre, closing up the mouth of the tube. [A. S.]

**LEUCO.** In Greek compounds = white: thus *leucocarpus* is white-fruited; *hypoleuca*, white beneath, &c.

**LEUCOBRYUM.** A genus of acrocarpous mosses, having the white hue of *Sphagnum*, and agreeing with *Dicranum* in the capsule and peristome, but distinguished by the peculiar structure of the external leaf-cells. These are disposed in two or more strata, and are large and rectangular, void of chlorophyll, and communicating with each other by means of circular apertures. The chlorophyll cells are imbedded in the centre of the leaves. Our only species, *L. glaucum*, occurs in the same sort of situations as *Sphagnum*, forming large tufts, which, however, seldom fructify: it agrees in the general appearance of the foliage with *Leucophanes* and *Octoblepharum*, and occurs in America and in the southern hemisphere. There are several exotic species. [M. J. B.]

**LEUCOCORYNE.** A genus of Chilian herbs of the order *Liliaceæ*. They have fleshy roots, linear leaves, and umbels of white or blue flowers supported on scapes. These flowers have a hypocrateriform perianth; three fertile stamens inserted in the middle of the tube, and three sterile fleshy ones seated in the throat; and a terminal style articulated with a sessile ovary, and having a simple stigma. [T. M.]

**LEUCOJUM.** A genus of European *Amaryllidaceæ* comprising a few very pretty bulbous plants called Snowflakes. They bear considerable general resemblance to snowdrops, but are larger, and the six perianth segments are nearly equal. They have sheathing erect linear lorate leaves, and hollow angular scapes, the flowers being campanulate, and white tipped with green. The six stamens are inserted on an epigynous disk, and their anthers open by a terminal pore, and also by a lateral exterior slit, not extending to the base. *Erinosema* and *Acis*, represented by *L. vernum* and *L. autumnalis*, were formerly included. The common species is *L. aestivum*. [T. M.]

**LEUCOLÆNA.** A genus of umbellifers, having the border of the calyx five-lobed; and the fruit compressed, each half with seven to nine narrow ribs. The species are natives of New Holland, generally of small size, and usually covered with fine down. The name indicates the white appearance of the bracts. [G. D.]

**LEUCOMERIS.** A Himalayan shrub or thick-stemmed erect herb, with long leaves

hoary underneath, and numerous flower-heads in a terminal corymb, forming a genus of *Compositæ*, scarcely differing from the American *Gnaphalium*.

**LEUCOPHÆ.** A genus proposed by Webb for the shrubby species of *Sideritis* from the Canary Islands, but which have generally been maintained as a section only of *Sideritis*, under the older name of *Marrubium* of Mönch.

**LEUCOPOGON.** A large genus of *Epacridaceæ*, distinguished by having a five-lobed calyx, with two or three bracts at the base; a funnel-shaped corolla with five spreading lobes; five anthers on very short filaments which are included within the corolla; and a style thickened at the base, bearing a capitate stigma. The fruit is either a berry or a dry capsule. The flowers are white in terminal or axillary spikes, and the leaves are lanceolate slightly toothed or hairy at the margin. They are handsome shrubs found in most parts of Australia, Tasmania, and New Zealand. [R. H.]

**LEUCOPSIDIUM.** A genus of *Compositæ* established by De Candolle in the tribe *Anthemideæ*, for some North American plants since reduced to *Egletes*. *L. arkansum* is sometimes met with in gardens.

**LEUCORCHIS.** A genus of Java orchids consisting of terrestrial, perhaps leafless, herbs, having scapes bearing racemes of whitish flowers. They belong to the *Arethuseæ*, and have the leaflets of the perianth connate at the base, the lateral sepals forming an emarginate lower and the dorsal sepal with the petals a trifid upper lip, while the labellum is roundish undivided and spreading, articulate with the column. [T. M.]

**LEUCOSMIA.** A genus of *Aquilariaceæ*, consisting of a shrub, native of the Friendly Isles. It has opposite entire leaves, and terminal heads of flowers, surrounded by a deciduous involucre. The perianth is tubular, coloured, with five petaloid scales in its throat; stamens ten, in two rows; ovary girt round at the base by a short sheath, with a solitary ovule in each of its two compartments; fruit fleshy. [M. T. M.]

**LEUCOSPERMUM.** A notaceous genus consisting of shrubs or small trees, natives of South and South-eastern Africa, reaching to the tropic. They are known by having a four-cleft silky calyx, the concave segments of which occasionally cohere, and each bear a sessile anther; style filiform, with a smooth stigma. The seed-vessel is one-celled, and contains a single smooth wingless seed. The involucre is imbricated, and the yellow flowers are borne in terminal globose heads; leaves sessile, of a leathery texture, often toothed at the apex, and generally covered with silky hairs. [R. H.]

**LEUCOSTEGIA.** *Acrophora*.

**LEUCOSYKE.** The name of a small tree, native of Java, forming a genus of *Moraceæ*. The leaves are stalked, ovate, sharply pointed, white and hoary on the

lower surface, with large stipules; and the flowers are unisexual, grouped in axillary globose heads, the males stalked, and the females sessile. The ovary contains a single ovule. [M. T. M.]

**LEUCOTHAMNUS.** A name proposed by Lindley for two or three species of *Thomasia*, in which the cup formed by the united base of the filaments is more adnate to the calyx, thus rendering the insertion of the stamens more perigynous than in the other species.

**LEUCOTHOË.** One of the subgenera of *Andromeda*.

**LEUZEA.** A genus of unarmed perennial composite herbs related to thistles, found in Eastern Australia, and in the Mediterranean region, and Siberia. Their unbranched stems are furnished with entire or pinnatifid leaves, and terminate in a single rather large ovate or globose flower-head, which contains numerous purple tubular florets, enclosed by an involucre of many series of silvery scales extended into thin dry membranous tips. The nature of these scales serves to distinguish the genus from some of its allies, and the feathery pappus-hairs which crown the four-sided achenes from others. [A. A. B.]

**LEVENHOOKIA.** A small genus of *Stylidiaceæ* consisting of minute herbaceous plants natives of King George's Sound, South-west Australia, and distinguished by having a five-cleft calyx with two lips; the limb of the corolla five-parted and irregular, the fifth segment or lip being dissimilar to the others, arched and longer than the erect column; the lobes of the anthers lie one above the other; there are two hair-shaped stigmas, and a one-celled capsule. The leaves are alternate, crowded at the tops of the branches, and intermixed with fascicles of flowers. [R. H.]

**LEVERWOOD.** *Ostrya virginica*.

**LEVISTICUM.** A genus of umbellifers, distinguished by having each half of the fruit with five wings, the two lateral of which are broader than the others. The only species is an herb, native of the Pyrenees; it contains an abundant yellow juice, and is employed as a domestic remedy. [G. D.]

**LEWISIA rediviva**, the Bitter-root plant or *Racine amère* of the Canadians, the *Spatium* or *Spmitum* of the Oregon Indians, is the only species of this singular genus of *Mesembryaceæ*. It is a somewhat succulent stemless perennial, with a fleshy tapering root, from the summit of which arise numerous clusters of narrow succulent green leaves; and in the centre a fleshy stalk, jointed above the middle, and bearing a solitary rose-coloured flower, surrounded by an involucre of five to seven narrow scales. As soon as the flower opens, the leaves begin to wither and dry up, usually lasting only a few days, the entire period of the plant's existence above ground not exceeding six weeks, viz. from early in May

till the middle of June. The flower, which remains open only during sunshine, has a persistent calyx, a corolla of eight to ten spreading petals, numerous stamens, and a one-celled ovary, in which respect it differs from allied genera.

This extremely curious plant is a native of the Upper Oregon territory, and its roots, which are largely collected by the Indians, afford a wholesome though bitter-tasted food, being composed almost entirely of starch. When fresh, these roots are covered with a dark-brown skin, and are bright-red within, but when skinned and dried for preservation they are nearly white. The specific name, *rediviva*, was given to the plant in consequence of the growth of some dried and apparently dead roots taken from an herbarium specimen. [A. S.]

**LEYCESTERIA.** A genus of *Caprifoliaceæ*, having the border of the calyx five-parted, the pieces narrow and unequal; and the fruit a berry with five cells and numerous seeds. The only species is *L. formosa*, a shrub, chiefly confined to the higher parts of Nepal, and now well known as an ornament of our shrubby gardens. The name was given in honour of the late Mr. Leycester, of the Indian civil service, and a patron of horticulture. [G. D.]

**LEYSSERA.** A genus of *Compositæ*, of the tribe *Senecioneæ*, distinguished by the ray-florets being ligulate, female or neuter, with a pappus of short simple bristles, whilst the tubular and hermaphrodite disk-florets have a pappus of long plumose bristles, alternating with chaffy scales. It consists of three or four African herbs or undershrubs, with slender branches terminating in a long peduncle with a single yellow flower-head. The leaves are linear, and usually irregularly clustered.

**LÉZARDELLE.** (Fr.) *Saururus*.

**LHOTSKYA.** A genus of *Myrtaceæ*, of the section *Chamaelauciaceæ*, peculiar to South-western Australia, and consisting of trees and shrubs with acerose or tetragonous leaves, and yellow or violet flowers, arranged in terminal heads. The calyx, supported by two bracts, has ten ribs, and is five-cleft; the petals are five; the stamens indefinite; and the fruit an oblong ten-ribbed capsule, indehiscent, one-celled, and often only one-seeded. [B. S.]

**LIABUM.** A genus of *Compositæ*, differing from *Andromachia* in the pappus, which consists of a single series of filiform bristles; and like *Andromachia* usually referred to *Vernoniaceæ*, on account of the style, but the opposite leaves, yellow radiating flower-heads, and anthers with points at the base, are much more those of some *Senecionideæ*. There are several species, all South American, and not all sufficiently distinct from *Andromachia*.

**LIANE.** A woody twining or climbing plant like those which occur in tropical forests.

**LIANE À BLESSURES.** (Fr.) A West

Indian name for *Vanilla claviculata*. — A SIROP. A name given by the French colonists to *Columnea scandens*. — HOUGE. *Tetracera Figuera*.

LIARD. (Fr.) *Populus balsamifera*.

LIARDIER. (Fr.) *Populus nigra*.

LIATRIS. A genus of North American herbaceous plants, belonging to the tribe *Cichoraceae* of compound flowers, distinguished by having a naked receptacle, an oblong imbricated involucre, and a feathery pappus. Many of the species are pretty plants, well worthy of cultivation; among them *L. squarrosa*, a handsome species with very long narrow leaves, and large heads of beautiful purple flowers; *L. scariosa*, well marked by the involucreal scales, which are marbled with purple; *L. spicata*, which, as its name indicates, bears its flowers in a spike; and *L. odoratissima*, of which the leaves, when dry, give out a smell resembling vanilla. *L. scariosa* and *squarrosa* are called in North America Rattlesnake's Master, because the tubers bruised are considered a specific for the bite of that reptile. [C. A. J.]

LIBANOTIS. A genus of umbellifers, chiefly distinguished by having the border of the calyx in five slender awl-shaped and coloured divisions, which fall off before the fruit ripens. The species are herbs, natives of Europe and middle Asia; their leaves are pinnate, with ovate pinnae, cut or deeply incised. The name is from the Greek word signifying incense, indicating the odour of some of the species. [G. D.]

LIBER (adj.). Free: as when there is no cohesion between parts in contact with each other.

LIBER (subst.). The inner lining of the bark of Exogens, where alone its woody matter resides.

LIBERTIA. A small genus of *Iridaceae*, natives of Australia, Tasmania, New Zealand, and Chili, distinguished from *Sisyrinchium* by the stamens being distinct, or connate only at the very base, and having versatile anthers. The few species are herbs, with creeping rhizomes or fibrous roots, grassy leaves, and panicle inflorescence, with the flowers almost in umbels. The flowers are always white, except the sepals, which are occasionally greenish. [A. S.]

LIBOCEDRUS. Two Chilian and two New Zealand trees are all the known species of this genus belonging to the *Cupressaceae* section of conifers. They are closely related to the arborescens (*Thuja*), from which they differ by the scales of their cones being valvate, and having each only one seed at its base, and also by their seeds being unequally winged. One of the New Zealand species, *L. Doctiana*, the Kawaka of the natives, is a fine timber tree growing 60 or 100 feet high, and yields an excellent fine-grained heavy, dark-coloured wood, useful for both planks and spars; while the wood of *L. Bidwillii*, the other

New Zealand species, is so soft and porous that soap-bubbles may be blown through a piece a foot in length. Both the Chilian species, *L. tetragona* and *L. chilensis*, are timber trees of large size. The former is the Alerce of that country, and yields the South American timber of that name, which is largely used on the Southern Pacific coast, and forms an important article of trade to the Chilians. Spars eighty or ninety feet long are obtainable from it; and a single tree often yields 800 to 1,000 or even 1,500 boards. Its grain, too, is so straight and equal that it can be split into shingles, which look as though they had been dressed with a plane. [A. S.]

LIBIDIBI. A name given to the pods of *Cesalpinia* or *Libidibia coriaria*.

LIBRA. The best kind of tobacco grown in the western part of Cuba.

LICANIA. A genus of *Chrysobalanaceae*, containing about thirty-five species, mostly inhabitants of the forests of Guiana and Brazil. They are timber trees or large shrubs, and have large entire leathery leaves, and small flowers in terminal clusters. The Pottery tree of Pará (*Moguelia utilis*) was formerly referred to this genus; the ashes are used by the natives of the Amazon for mixing with the clay employed in the manufacture of pottery-ware, in order to enable the vessels to withstand the action of fire. The Indians call these trees Caralpe, but botanists have adopted that name for a genus of *Ternstroemiaceae*, owing to the Pottery tree having at one time been supposed to belong to that order. Mr. Spruce describes them as exceedingly straight slender and lofty trees, having trunks not exceeding twelve or fifteen inches in diameter, growing to a height of a hundred feet before sending forth branches, the wood being so hard that ordinary tools will not cut it. The bark is likewise exceedingly hard, and very gritty from the large quantity of silica it contains, and to which it owes its property. The Indians burn the bark, reduce it to powder in a mortar, and then mix it with an equal quantity of the best clay they can procure, using it for all kinds of utensils required to stand fire-heat. [A. S.]

LICCA TREE. *Sapindus spinosus*.

LICE, BEGGAR'S. An American name for *Cynoglossum Mortonii*.

LICHENS. A large tribe of cryptogams belonging to the fungal alliance, and distinguished from *Fungi* by their not deriving nutriment in general from the substance on which they grow, but from the surrounding medium; by their slow development and long endurance; and, technically, by their producing within their substance granules distinct from the general tissue, called gonidia, which in certain conditions are reproductive. In fructification they agree with ascomycetous *Fungi*, and like them have either a second form of fruit (stylospores) contained in distinct cysts (pycnidia), or minute bodies variously

horse, which are supposed to have the power of impregnation. On these points the memoirs of Tulane and Lindsay must be consulted by all who wish to have a complete knowledge of the subject. Lichens, perhaps, reach higher latitudes and altitudes, and are capable of enduring greater degrees of cold, than any other vegetables except *Diatomaceae*. On the contrary, they may be exposed to a burning sun without injury; and, though apparently dried up and withered, they recover their proper appearance with the first shower. Most of them are essentially air-plants, but a few are either constantly wet with spray, or totally immersed.

Lichens are divisible into two principal sections, according to the nature of the fruit, thus:—

1. *ANGIOMORPHI*: fruit contracted, like a *Sphæria*.

2. *GYMNOMORPHI*: fruit expanded, like a *Peziza*.

In each there is a distinct gelatinous or columaceous group; and various natural orders arise in either division from modifications of the fruit.

Nylander, who is perhaps the best modern authority on Lichens, divides them into three families, the vegetative element in his arrangement prevailing, as the fructiferous does in that of Acharius—*MYRIANGIACEI*, *COLLEMACEI*, and *LICHENACEI*, of which the two first are gelatinous. The *Lichens* proper he divides as follows:—

1. *EPICOLONI*: spores ultimately dusting the shields, as *Cuticium*.
2. *CLADONIOIDEI*: lichens with a stem-shaped thallus, as *Cenomyces*.
3. *RAMULOIDEI*: lichens with a shrubby thallus, as *Ureia*.
4. *PHYLLODEI*: lichens with a leafy thallus, as *Parmelia*.
5. *PLACODEI*: lichens with a crustaceous thallus, as *Lecidea*.
6. *PYRENODEI*: lichens with capsule-like fruit.

Lichens are in some cases useful as articles of food and medicine, but their principal economical value consists in their properties as dyes. [M. J. B.]

**LICHEN, CUP.** *Cenomyces punctata*, also called Cup-moss. — **HORSEHAIR.** *Corticularia jubata*, also called Tree-hair.

**LICHEN COMESTIBLE.** (Fr.) *Lecanora esculenta*. — **DES RENNES.** *Cenomyces rangiferina*. — **D'ISLANDE.** *Cetraria islandica*.

**LICHENOLOGY.** That part of Botany which treats of Lichens.

**LICHINA.** A small genus of gelatinous capsule-fruited lichens, remarkable for its species growing on rocks exposed to the spray or covered at high water. They were in consequence formerly referred to *Algae*, but their fructification is now well-known, and agrees in essential points with that of *collemata*. They are short-branched tufted lichens, with terminal fruit, which opens merely by a terminal aperture without any exposed disk. [M. J. B.]

**LICHWALE.** *Lithospermum officinale*.

**LICHWORT.** *Parietaria officinalis*.

**LICIET.** (Fr.) *Lyctum*.

**LICUALA.** A genus of palms comprising about a dozen species from India and the Indian Archipelago. With the exception of one New Guinea species, none exceed ten or fifteen feet in height, some scarcely having any stem at all, while others have slender stems marked with circular scars or rough with the hard bases of fallen leaves. Their leaves are terminal and fan-shaped, with prickly stalks, the prickles being conical or often hooked; and their branching flower-spikes, with numerous incomplete spathes, stand almost erect, or hang down from amongst the leaves. The flowers have a cup-shaped three-cut calyx, and a three-parted corolla, and are all perfect.

*L. acutifida* yields the walking-sticks known by the curious name of Penang Lawyers. It is a native of the island of Pulo-Penang, where it grows generally to a height of about five feet, but occasionally higher, its stems averaging about an inch in diameter, except at the very base, where they are considerably thicker. In order to convert these stems into walking-sticks, they are carefully scraped so as to remove the rough outside portion, then straightened by means of fire-heat, and afterwards polished, but those brought to this country come in an unpolished state. [A. S.]

**LID-FLOWER.** *Calyptanthus*.

**LIEBERKUHNI.** A genus of *Compositae*, founded by Cassini on a Montevideo plant, with the habit of *Leria*, and scarcely sufficiently distinct from that genus.

**LIEBIGIA.** A genus of *Cyrtandraceae* peculiar to Japan and the Moluccas, and consisting of erect or climbing shrubs, with opposite equal or unequal serrated leaves, and axillary peduncles bearing blue violet-coloured flowers. The calyx is tubular, four to five-cleft, the corolla funnel-shaped, the stamens four, two of them sterile, and the capsule elongated, pod-like, two-valved, and falsely four-celled. [B. S.]

**LIÈGE.** (Fr.) *Quercus Suber*.

**LIÈRE.** (Fr.) *Hedera Helix*. — **Dt** **COPENHAGEN** or **D'ÉTÉ.** *Senecio mikanioides*, sometimes called *Delavrea scandens*. — **GRIMPANT.** *Hedera Helix*. — **TER-RESTRE.** *Nepeta Glehoma*.

**LIF, LIEF, LOOF.** Names for the fibre by which the petioles of the date-palm are bound together.

**LIFF, or LOUF.** *Infus acutangula* and *egyptiaca*.

**LIGEA.** One of the genera of *Podostemaceae*, consisting of aquatic herbs, natives of Guiana. According to M. Tulane, the able investigator of these humble plants, the species have larger stems than is usual in this order, these stems being either single, or tufted and curiously wavy, and the leaves alternate in two rows, decurrent, and of various shapes. The flowers are

placed on long stalks, which are grouped together in cymes, and are further distinguished by the number of stamens, and the smooth, not ribbed capsule, whose valves are of equal size. [M. T. M.]

**LIGHTFOOTIA.** A genus of bellworts, having the filaments of the anthers broad and ciliated at the lower part, and the style beardless, its summit short, and with narrow divisions. The species are mostly small shrubs, and natives of the Cape, with small stalkless leaves which are alternate or opposite. The name was given in honour of the Rev. J. Lightfoot, author of a Flora of Scotland. [G. D.]

**LIGHTWOOD.** *Acacia Melanoxydon*; also *Ceratopetalum apetalum*.

**LIGN-ALÔES.** The fragrant wood of *Aloxylium Agallochum*.

**LIGNEOUS, LIGNOSE.** Having the texture of wood; or of belonging to wood.

**LIGNUM.** The wood; that central part of a stem which lies below the bark, or its equivalent, the cortical integument.

**LIGNUM CAMPECHIANUM.** Logwood — **COLUBRINUM.** A drug obtained from *Strychnos Igustrina*, and perhaps other species. — **RHODIUM.** The wood of *Amrys balsamifera*, and *Rhodorrhiza scoparia*.

— **VITÆ.** The wood of *Quercus officinale*, or perhaps of other species. — of N. S. Wales. *Eucalyptus polythamnos*; also *Acacia falcata*. — of New Zealand. *Metrosideros scandens*. —, **HASTARD.** *Budiera diversifolia*.

**LIGULE.** A strap. The radiant florets of certain composites; also the membrane which occurs at the base of the lamina of a grass-leaf; also certain appendages found on the coronet of some asclepiads, alternating with the horns and spreading over the corolla.

**LIGULARIA.** A genus of *Compositæ*, closely allied in habit and character to *Senecio*, and scarcely differing from some of the large-flowered herbaceous species, except in a tendency of the ray-florets to assume a bilabiate form, and in the anthers to have points at the base. The species are all natives of the mountainous regions of Asia, and have been more generally known as species of *Cineraria* or of *Senecio*. One only, *L. sibirica*, extends into the mountains of central Europe. It is a showy marsh plant, with broadly cordate leaves, and large yellow radiating flower-heads, in a simple terminal spike.

**LIGULATE.** Strap-shaped; narrow, moderately long, with the two margins parallel.

**LIGULIFLORÆ.** A name applied to a suborder of *Compositæ*, in which all the florets in the head of flowers are ligulate, and each of the florets has stamens and pistil. This suborder corresponds to the *Cickoraceæ* of Jussieu. [J. H. B.]

**LIGULIFLOUS.** Having a capitulum composed exclusively of ligulate florets.

**LIGUSTICUM.** A genus of umbellifers, having the fruit nearly round, each half of it with five sharp ribs, and numerous oil-vessels in the furrows. The species are perennial herbs, widely distributed, being found, some in North America, others in central Asia. *L. scoticum*, a native of many parts of the British coast, is sometimes used as a potherb. [G. D.]

**LIGUSTRUM.** The common Privet of our hedges is the most familiar and only European representative of this genus of *Oleaceæ*, but there are about twenty other species, which belong principally to China, Japan, and Northern India. They are mostly large shrubs from six to ten feet high, but some form trees, which in India attain a considerable height. They have opposite entire leaves, usually oblong egg-shaped or lanceolate; and the flowers are small and white, disposed in thyrses-like panicles at the ends of the young branches; they have a cup-shaped deciduous four-toothed calyx, and a funnel-shaped four-lobed corolla; and the fruit is globular, and contains two one-seeded cells.

*L. vulgare*, the common Privet, a native of most parts of Europe, is otherwise called Prim or Prim-print, in consequence of one of its chief uses being for the formation of hedges in ornamental gardens, owing to its bearing clipping or being kept in prim order without injury; and its generic name is said to be derived from the Latin *Igo*, to tie, on account of the long straight shoots being used in many places instead of osiers for tying, &c. It seldom grows higher than eight or ten feet, and has a short crooked trunk; but its wood is only large enough for turnery purposes, for which its hardness and whiteness render it suitable. Its purplish-black berries, which during winter afford food for many kinds of birds, yield an oil by pressure, and their juice is used in Germany for painting playing-cards and similar articles, and in other countries for colouring inferior descriptions of port wine. A bitter extract called *Igustrina* is obtained from the bark; and in Belgium the dried and powdered twigs are used for tanning purposes. [A. S.]

**LILAC.** Pale dull violet, mixed a little with white.

**LILAC.** *Syringa vulgaris*. —, **AFRICAN.** *Melia Azedarach*. —, **AUSTRALIAN.** A name used by the settlers for *Hardenbergia monophylla*; also *Prostanthera violacea*. —, **INDIAN.** *Melia* —, **PERSIAN.** *Syringa persica*.

**LILAS.** (Fr.) *Syringa vulga*. — **DE MARLY.** *Syringa purpurea*. — **DE ROUEN.** *Syringa dubia*. — **DES INDES.** *Melia Azedarach*. — **DE TERRE or TERRESTRE.** *Muscari monstrosum*. — **VARIN.** *Syringa dubia*.

**LILIACEÆ.** (*Hamercallidæ*, *Tulipaceæ*, *Coronariæ*, *Asphodelæ*, *Asparagus*, *Convallariaceæ*, *Lilyworts*, &c.) A natural order of monocotyledonous plants belonging to

the subclass *Petaloides*, and constituting the type of Lindley's liliaceous alliance of Endogens. Herbs, shrubs, or trees, with bulbs, corms, rhizomes, or fibrous roots, simple sheathing or clasping leaves, and regular flowers. Perianth coloured, of six leaves or six-lobes; stamens six, inserted on the perianth, the anthers introrse; ovary three-celled; style one; stigma simple or three-lobed. Fruit three-celled, capsular, or succulent; seeds in one or two rows, sometimes in pairs or solitary; albumen fleshy. They are natives both of temperate and tropical regions, and emetic, purgative, and diaphoretic in their qualities. Certain species of *Aloe* supply the aloes used in medicine. *Urginea Scilla* furnishes a bulb which is used medicinally under the name of squill. New Zealand flax is prepared from *Phormium tenax*. Onions, leeks, garlic, chives, shallot, rocambole, tulips, the resin called dragon's blood, &c., are all furnished by plants belonging to this extensive order, which comprises upwards of 150 genera and 1,200 species. *Tulipa*, *Agapanthus*, *Yucca*, *Hyacinthus*, *Asphodelus*, and *Dracena*, are examples of the principal groups. [J. H. B.]

**LILUM.** The genus which gives its name to the order *Liliaceæ*. It embraces a considerable number of species, all of which belong to the northern hemisphere, and, with the exception of the few found in the mountains of sub-tropical Asia, to the temperate regions. Several are Japanese, and from that country our gardens have lately been enriched with certainly the finest species of the genus, *L. auratum*, the stem of which, two to five feet high, bears a dozen or more magnificent flowers, each as much as a foot across, studded with purple spots and blotches on an ivory-white ground, their sepals and petals being also marked with a conspicuous stripe of yellow down their middle. Other Japanese species, such as *L. laucifolium*, *L. speciosum*, and *L. japonicum*, are also in much request in our gardens on account of the beauty of their flowers. *L. candidum*, the White Lily and the *Krisan* of the Greeks, and *L. rhododendricum*, are both found in Palestine, Syria, and other Eastern countries, and are sometimes pointed out as the Lilies of the Field; but as the true lilies do not form a very conspicuous feature in Eastern scenery, it has been suggested that the plant alluded to by our Saviour was *Anemone coronaria*, which is there extremely abundant, and would be more likely to attract attention. The bulbs of several species are eaten, such as those of *L. kamschatkense* in Kamtschatka, of *L. Martagon* by the Cossacks, of *L. tigrinum*, the Tiger Lily, and others, in China and Japan. Some medicinal uses have also been ascribed to various species, but none have any very marked properties in that respect.

All Lilies are herbs with scaly bulbs, whence arise tall slender stems, furnished with alternate or somewhat whorled leaves, and bearing upon their summit a few large, showy, erect or drooping flowers. These

flowers have a perianth of six distinct or very slightly cohering segments, which are narrow and erect at the bottom, but broader, and spread or curve outwards towards the top; and at the base of the perianth the six stamens are inserted. Their three-celled ovary terminates in an elongated style bearing a three-angled or three-lobed stigma; and ripens into a three-valved capsule containing numerous horizontal winged seeds. [A. S.]

**LILY.** *Lilium*. —, AFRICAN. *Agapanthus umbellatus*. —, ATAMASCO. *Zephyranthes Atamasco*. —, BARBADOS. *Hippeastrum equestre*. —, BELLADONNA. *Anaryllis Belladonna*, the *Belladonna purpurascens* of some modern botanists. —, BLACKBERRY. An American name for *Parianthus chinensis*. —, BOURBON. *Lilium candidum*. —, BRISBANE. *Euryclis australasica*. —, CAPE COAST. *Cri num spectabile*. —, CORFU. *Punkia subcordata*. —, CURAN. *Scilla peruviana*. —, DAY. *Hamorocallia*. —, FIRE or FLAME. *Pyrolisum*. —, FLAX. *Phormium tenax*. —, GOLDEN. *Lycoaria*. —, GUERNSEY. *Nerine carolinensis*. —, IXIA. *Ixiolirion*. —, JACOB. *Erythraea (Amargilla) formosissima*. —, KNIGHT'S-STAR. *Hippeastrum*. —, LENT. *Narcissus Pseudo-Narcissus*. —, MEXICAN. *Hippeastrum regium*. —, OF THE VALLEY. *Convallaria majalis*. —, PERSIAN. *Fritillaria persica*. —, POND. *Nymph*. —, ROCK. *Scilla ginelei convoluta*. —, ROCKWOOD, or N. Zealand. *Ranunculus Lyallii*. —, ST. BRUNO'S. *Anthericum Liliistrum*. —, SCARBUROUGH. *Yallota purpurea*. —, SUPERB. *Methonica superba*. —, SWAMP. *Zephyranthes*. —, TRUMPET. *Richardia cethiopica*. —, TURK'S CAP. *Lilium Martagon*. —, WATER. *Nymphaea*. —, WHITE. *Lilium candidum*. —, WHITSUN. *Narcissus poeticus*.

**LILY-PINK.** *Aphyllanthes*.

**LILY-THORN.** *Catesbaea*.

**LILYWORTS.** Lindley's name for the *Liliaceæ*.

**LIMATODIS.** A genus of *Orchidaceæ*, nearly allied to *Calanthe*, from which it differs in having the lip quite free from the column instead of being united with it. It contains a few terrestrial species, natives of India and Java, the most familiar of them being *L. rosea*, a Moulmein plant with fusiform pseudobulbs, oblong lanceolate plaited leaves, and a many-flowered scape of very handsome bright rose-coloured flowers, having a straight blunt spur, and an oblong flat lip. [T. M.]

**LIMA-WOOD.** The finest description of Nicaragua wood (*Cecropia echinata*) produced in South America.

**LIMB.** The flat expanded part of a petal.

**LIMBATE.** Having one colour, surrounded by an edging of another

**LIME.** *Citrus acida*. —, OGEECHEE. *Nyssa candicans*. —, SWEET. *Citrus Limetta*. —, WILD. *Atalantia monophylla*.

**LIME TREE.** *Tilia europæa*.

**LIMETTE. (Fr.)** *Citrus Limetta*.

**LIMEUM.** A genus of *Phytolaccaceæ*, differing from most of the order in having a membranous seed-coat, and by the presence of petals, which, however, are often suppressed. They are African annuals or undershrubs, with branched procumbent stems, alternate fleshy entire leaves, and flowers in compact cymes, having a five-parted calyx, often coloured within, five petals when present, usually seven stamens, two styles, and a subglobose indehiscent fruit. [J. T. S.]

**LIMNANTHEMUM.** This name, Marsh-flowers, is applied to a genus of *Gentianaceæ*, consisting of aquatic plants, with roundish floating leaves, and yellow flowers. The calyx is five-cleft; the corolla rotate, or funnel-shaped, fringed with hairs in the interior; and the capsule bursts irregularly when ripe, by which latter circumstance the genus is distinguished from *Villarsia*, to which otherwise it is very closely allied. *L. nymphæoides* is one of our most beautiful water plants, having leaves like those of a waterlily, but smaller, and large funnel-shaped yellow fringed flowers. (It is a native of England, from Norfolk and Gloucester to Sussex; and is naturalised farther north, and in Scotland and Ireland.) [M. T. M.]

**LIMNANTHES** *Douglasii*, a sweet-scented ornamental annual, introduced from California by Douglas, belongs to the *Tropæulaceæ*, and is distinguished from *Tropæolum* by having the flowers regular. The stems are prostrate; the leaves pinnate, with an odd or terminal three-cleft leaflet; the peduncles one-flowered, and the petals five, yellow and white, emarginate. The whole plant partakes of the pungent properties of the Indian cresses, or, as they are often popularly called, nasturtiums. [C. A. J.]

**LIMNOBIUM.** A genus of American *Hydrocharidaceæ*, of which *L. spongiosum*, the North American Frogbit, and *L. Sinclairii*, from Guatemala, are the only known species. They very closely resemble our English frogbit in appearance, so much so indeed that without flowers it is difficult to distinguish them: and like it, they are aquatic plants, floating in stagnant water and propagating themselves freely by means of runners. Generally they are distinguished by the spathe of the male plants being one-leaved, and producing about three long-stalked flowers, which have the stamens completely united into a central column, bearing from six to twelve narrow anthers at unequal heights. In the female plants the spathe is two-leaved, and produce a single short-stalked flower. [A. S.]

**LIMNOCHARIS.** A perennial herbaceous aquatic, belonging to the order *Saxifragæ*. The leaves are broadly heart-shaped, oblong; and the flowers on long stalks, with three sepals, and as many delicate yellow radaceous petals, shaded with orange near the claw. Two species are

cultivated, *L. Plumieri* and *L. Humboldtii*, both South American. [C. A. J.]

**LIMNONESIS.** A genus of *Pistiacæ*, consisting, as the name implies, of plants growing in wet marshy places, chiefly in tropical America. The genus is closely allied to *Pistia*, but is distinguished by the stalked leaves, and by the spadix, which does not extend beyond the attachment of the anthers, which latter are two or three in number. The fruits contain two seeds only. [M. T. M.]

**LIMODORUM abortivum** is a leafless erect terrestrial orchid, forming a genus of the tribe *Neottieæ*. It is found in dry shrubby places and woods, in Central and especially Southern Europe, and is believed to be parasitical on the roots of shrubs. It grows to the height of one or even two feet, and assumes more or less of a purple colour; the stem bears a few sheathing scales or bracts; the flowers are rather large of a dingy purple in a simple loose spike; the sepals and petals are nearly alike and erect; the lip, also erect, is prolonged into a spur at the base; the column is elongated, with an oblong erect anther on the summit.

**LIMON. (Fr.)** *Citrus acida*. — **DOUX.** *Citrus Limetta*.

**LIMONELLIER. (Fr.)** *Limonia*.

**LIMONIA.** A small genus of *Avranciaceæ*, two species of which are natives of India and Ceylon, one of Mauritius, and another of Madagascar. They are shrubs with trifoliate or pinnate leaves, and the flowers with a four or five-lobed calyx, a similar number of whitish petals, twice as many free stamens, and a four or five-celled ovary. The fruit is poly.

*L. acidissima* is a spiny shrub, native of the East Indies, growing eight or ten feet high, and having pinnate leaves with winged stalks, and racemes of white flowers, producing round fruits about the size of damson plums, and of a yellowish colour, changing to a reddish or purplish tint. The Javanese employ the extremely acid flesh-coloured pulp of these fruits as a substitute for soap; and on the coast of Malabar they are used medicinally. [A. S.]

**LIMOO.** A name used in some of the Pacific Islands for Seaweed.

**LIMOSELLA.** Mudwort, a genus of humble aquatic annuals belonging to the *Utriculariaceæ*, among which they are distinguished by their campanulate regular corolla, and one-celled capsule. *L. aquatica*, the only British representative of the genus, is a minute plant, growing in muddy places and the banks of ponds, sending up from the creeping roots clusters of narrow smooth leaves, and inconspicuous pale pinkish flowers. [C. A. J.]

**LIN. (Fr.)** *Linum usitatissimum*. — **DE LA NOUVELLE ZÉLANDE.** *Pharbitis linax*. — **VIVAGE.** *Linum abrot-*

**LINACEÆ. (Linen, Flaxwort.)** A natural order of dicotyledonous plants belonging to Lindley's geraniul alliance of hypogynous Exogens. Herbs with entire, sessile, alternate opposite or verticillate leaves, which are exstipulate, or which have occasionally a pair of minute glands at the base. Flowers regular and symmetrical; sepals three to five, imbricate; petals three to five, contorted in aestivation; stamens united at the base, three to five, usually with intermediate abortive ones in the form of teeth opposite the petals; ovary three to five-celled; styles three to five. Fruit six to ten-celled; seeds one in each cell; embryo straight. Abundant in Europe and North Africa. The plants yield mullage and fibre. Flax and linseed are procured from *Linum usitatissimum*. There are four genera and about ninety species. [J. H. B.]

**LINAIGRETTE. (Fr.) Eriophorum.**

**LINARIA.** A genus of herbaceous plants belonging to the *Scrophulariaceæ*, among which they are well marked by their perianate corolla (the mouth of which is closed by a prominent palate), spurred at the base, and by the capsule opening with teeth at the extremity. The most common English species is *L. vulgaris*, Yellow Toad-flax, characterised by erect stems one to two feet high, numerous glaucous linear leaves resembling those of flax, and terminal racemes of crowded yellow and orange flowers. A singular variety of this species, named *Peloria*, is sometimes found with five spurs and regular flowers. *L. Cymbalaria*, Ivy-leaved Toadflax or Mother-of-thousands, is frequent on ruins and old garden walls. Among the cultivated kinds *L. speciosa* is a popular border annual; and *L. tricornithophora* is remarkable for the singular form of the flowers, which resemble, as its trivial name indicates, three birds seated in the spur. French, *Linaire*; German, *Flackkraut*. [C. A. J.]

**LINCONIA.** A genus of bruniads, having the border of the calyx in five smooth short divisions; the corolla of five lanceolate pieces, folded and concealing the five stamens, the anthers of which have the two halves separated at the base; and the seed-vessel with two cells, each of which is usually two-seeded. The species are natives of the Cape, with the habit of heaths, the branches numerous and erect, the leaves spirally arranged, and the flowers solitary in the axils of the upper leaves. [G. D.]

**LINDACKERIA. Mayna.**

**LINDELÖFIA.** A genus of *Boraginaceæ* from Kashmir, consisting of biennial or perennial plants with the habit of *Anchusa*, but an ovary like that of *Cynoglossum* or *Omphalodes*. The corolla is blue or purplish, funnel-shaped, with a long tube and erectopent five-parted limb, the throat open, with five erect notched smooth scales. The nectary is depressed ovate-deltoid, rough or prickly margined, with a border of long hooked prickles. [J. T. S.]

**LINDEN.** The Lime tree, *Tilia europæa*.

**LINDENBERGIA.** A genus of *Scrophulariaceæ* of the tribe *Gratioleæ*, consisting of annual or perennial herbs, of a weedy aspect, usually more or less hairy, and allied in the shape of their flowers to *Stimulus*, with the stamens of *Stemodia*. The leaves, at least the lower ones, are opposite, the flowers yellow or ..... either solitary in the axils of the leaves or forming terminal spikes; the calyx is five-cleft; the corolla is tubular, with an erect notched upper lip, and a large spreading lower lip with a convex palate; the stamens are didynamous, the cells of the anthers distinct from each other and stipitate. The capsule opens loculicidally in two valves. There are eight species known, natives of the warmer parts of Asia and Eastern Africa.

**LINDENBLOOMS.** Lindley's name for the *Tiliaceæ*.

**LINDENIA.** A genus of cinchonaceous plants, represented by a shrub, native of Guatemala. The flowers are arranged in terminal corymbs, with oblong bracts. The calyx tube is roundish, marked by five ribs, its limb divided into five narrow erect segments; the corolla is salver-shaped, with a very long tube, the limb with five oblong spreading lobes; anthers five, sessile; capsule two-celled, crowned by the limb of the calyx. The genus differs from *Aeghæa* in the long slender cylindrical tube of the corolla, and in its smooth style. *L. raiata* is a stove evergreen with large handsome white flowers. The genus is dedicated to M. Linden, a horticulturist of Brussels. [M. T. M.]

**LINDERA.** See *BERZOIX*. The name *Lindera* is, however, preferred by Meisner, to whom we owe the most recent account of the *Lauraceæ*, and who includes under it about a dozen species.

**LINDERNIA pyxidaria** is a small European annual, forming a genus of *Scrophulariaceæ* of the tribe *Gratioleæ*, and the type of a subtribe distinguished by the valves of the capsule being entire and parallel to the dissepiment. It is much branched, quite glabrous, and seldom attains six inches in height. The leaves are small, opposite and entire; the flowers small, pale pink or white, on axillary peduncles; the stamens didynamous, with arched filaments; the two-celled anthers cohering in pairs. It is a marsh plant, not uncommon in some parts of the continent, but not extending to Britain. It is named after Lindern, a Swiss botanist.

**LINDHEIMERIA.** A genus of *Compositæ* allied to *Melanopodium*, *Berlandiera*, and *Engelmannia*, consisting of a single Texan species, an erect dichotomous herb, with showy yellow radiating flower-heads on long slender peduncles. The involucre has four or five outer leaflike bracts, and as many internal flat oblong ones. The achenes of the ray are winged, with a short two-toothed pappus, those of the disk

abortive, enclosed in the scales of the receptacle.

**LINDLEYA** *mespiloides* is the sole representative of a genus named by Humboldt and Kunth in honour of one of the editors of the present work. It is a small evergreen tree or large shrub, found wild in the mountain regions of Mexico, and belongs to the *Quillaja* group of *Rosaceæ*, separated from the other groups of the order by its follicular or capsular fruits, and winged seeds. Amongst these *Lindleya* is distinguished by its five ovaries being consolidated, but having the styles distinct; and by its fruit being a hard bony five-celled and five-angled capsule, which splits open when ripe down the centre of the cells, each of which contains a couple of thin-winged seeds. It has simple crenulate shining leaves of an oblong-acute form, and solitary large white sweet-scented flowers, borne on the tips of its branchlets. [A. S.]

**LINDSÆA**. A rather extensive genus of polyopodiaraceous ferns, typical of the section *Lindsæeæ*, a group in which the transverse more or less elongated sori are indusiate, with the indusium attached along the inner, and opening along the outer margin, the reverse of what occurs in *Pteris*. Among these, *Lindsæa* is known by its veins being free. The fronds are very variable in character, some being simple, others pinnate, and others bipinnate, generally with a more or less adiantoid aspect. They are found in the tropics both of the old and New World. The name is sometimes incorrectly written *Lindsaya*. [T. M.]

**LINE** (adj. **LINEALIS**). The twelfth part of an inch.

**LINEA TRANSVERSALIS**. The ostiolum of certain fungi.

**LINEAR**. Narrow, short, with parallel margins; as the leaf of the yew-tree.

**LINEATE**. Lined; marked by fine parallel lines.

**LING**. *Calluna vulgaris*; also a Chinese name for *Trapa bicornis*.

**LINGUA CERVINA**. *Scolopendrium*. — **DE PIN**. *Casearia lingua*.

**LINGUIFORM**. Having the form of a tongue.

**LINNÆA**. This genus was so named by Gronovius in honour of the great Swedish naturalist Linnæus, who himself selected it as the most appropriate plant to bear his name, he having first pointed out its true character, besides which it was also an especial favourite with him, and common in his own native country. There is only one species, *L. borealis*, an extremely elegant little creeping evergreen plant, with slender branches a foot or more in length trailing along the ground, bearing small opposite broadly ovate or obovate leaves slightly toothed at the top, and sending up erect thread-like flower-stalks, which fork near the top and bear two gracefully

drooping highly fragrant bell-like flowers, of a pale pink colour or nearly white, and almost half an inch in length. These very beautiful little flowers have a calyx with a border of five teeth; a bell-shaped corolla narrow at its base but spreading upwards and dividing into five nearly equal lobes; four stamens, two of which are shorter than the other two; and a globular hairy three-celled ovary, which ripens into a dry one-seeded fruit. It grows almost exclusively in woods, and is widely dispersed over Northern Europe and Asia, and North America, occurring also in the mountains of Central Europe. In Britain it is found only in the east of Scotland, and in one place in Northumberland. According to Dr. Clarke, its scent is so powerful, especially at night, that it may be discovered at a considerable distance. The Lapianders use a decoction of its flowers as a remedy in rheumatic complaints, and the Norwegians consider a decoction of the entire plant good against the itch. It belongs to the *Cupressifoliaceæ*. [A. S.]

**LINOSTIGMA**. A genus proposed by Klotzsch for a species of *Viola*, in which the parts of the flower are reduced to four, those of the pistil to two, and the styles are united nearly to the middle. Like the other species of *Viola*, it is a native of extra tropical South America.

**LINOSTOMA**. A genus of Indian shrubs belonging to the *Thymelacææ*. The leaves are opposite, closely feather-veined, leathery, and shining; the flowers perfect, in terminal contracted racemes, the stalks of which are jointed in the middle. The perianth is tubular, coloured, and has ten petaloid scales placed in pairs opposite the five segments of its limb. The fruit is dry, not surrounded by any disk, nor, as happens in some adjacent genera, by the base of the perianth. [M. T. M.]

**LINOSYRIS**. A genus of *Compositæ* of the tribe *Asteroidæ*, consisting of erect herbs or undershrubs with alternate narrow crowded leaves and yellow flower-heads at the ends of the branches, forming a flat terminal corymb. The involueral bracts are not numerous, imbricated, the outer ones loose, passing into the leaves; the florets are all tubular and hermaphrodite, on a flat honeycombed receptacle without scales. The achenes are oblong, compressed, silky, with a pappus of simple bristles in a double row. There are about a dozen species, natives of Europe, temperate Asia, Northern Africa, or North America, among which *L. vulgaris* is not uncommon in hot exposed stony places in Central and Southern Europe.

**LINSEED**. The seed of Flax, *Linum usitatissimum*.

**LINUM**. A genus which gives its name to the *Linacææ*, consisting of herbs and small shrubs, natives of all the temperate regions of the globe, but rare in the tropics. The leaves are alternate, opposite, or even whorled; and the flowers, which are

variable in colour and very fugitive, grow in panicles or corymba. The calyx consists of five sepals; the corolla of five petals; and the stamens, which are the same in number, are connected into a tube at the base, and between them are five filaments, which are rudiments of stamens. The ovary is from three to five-celled, with the same number of styles and capitate stigmas; the capsule globular, most commonly ten-celled, from each cell being partially or completely divided in two by a spurious dissepiment, and each cell thus formed contains a single pendulous seed.

The species are numerous, but very few of them are of any importance except *L. usitatissimum*, the common annual Flax, which has been an object of cultivation from the earliest times. This plant has, for the most part, solitary quite erect stems, alternate smooth linear-lanceolate leaves, and a corymbose inflorescence; the sepals are ovate-acute with a membranous margin; and the petals are blue, three times longer than the calyx. The finer kinds of the linen of commerce are manufactured from the ligneous fibre of the stems of this plant; and the seed, called Linseed, is scarcely less valuable on account of the large quantity of oil contained in the embryo. The seeds contain a mucilage which dissolved in water is demulcent and emollient, and the meal of the seed is used for poultices. The cake remaining after the oil is expressed is extensively used in fattening cattle. *L. catharticum*, remarkable for its erect much-branched stem, its opposite smooth obovate-lanceolate leaves, and small white flowers, is occasionally used in medicine, being bitter and purgative. [B. C.]

Flax (*L. usitatissimum*) is only known at the present day as a cultivated plant, or as occurring in a semi-wild state in places where it has escaped from cultivation. History tells us that it has been grown for its fibre from the earliest times of which we have any record, it being one of those plants which the wants of civilised man early taught him the use of; and the long period during which it has been an object of culture has doubtless, as in other known instances, so altered the appearance of the plant that it is not recognisable in its original form, if such exists at the present day. The Bible affords ample proof of the antiquity of the use of flax as a material for weaving cloth. We read (Gen. xii. 43) that Pharaoh clothed Joseph in fine linen, and in the account of the plagues with which the Egyptians were visited (Ex. ix. 31), we are told that the flax was smitten; from which passages it would appear not only that the art of weaving had reached a high state of perfection, but also that flax was one of the agricultural plants of Egypt at that early period; and this is confirmed by the representations of its culture which occur in ancient Egyptian pictures which have descended to us. Moreover, microscopists have proved that the cloth used for wrap-

ping round mummies, the antiquity of which is undeniable, was made of flax. Flax and linen formed an article of commerce between the ancient Egyptians and Greeks. The plant was also cultivated by the early Romans; but as their clothing was chiefly made of wool, it did not find much favour.

In modern times the culture of Flax is widely spread in the northern hemisphere, extending from the tropics in India to Egypt to the northern parts of Europe. The principal producing country, and that from which we obtain the greater portion of our supply, is Russia, flax being an important crop in the northern districts of that country; but large importations are likewise received from Belgium, Holland, Prussia, and other countries, our total imports in 1860 amounting to 1,464,810 cwts., in addition to which considerable quantity is annually produced in our own country, mainly, however, in the north of Ireland.

The processes which flax undergoes before it reaches the hands of the spinner, vary in different places, but the general principle is the same in all, and although numerous new processes have been invented for shortening the time occupied by the various stages, none has yet entirely superseded the old modes. They may be said to consist of six operations:—*Rippling*, which consists in the removal of the seed-capsules by drawing the stem through a kind of comb. *Steeping or watering*, the object of which is to facilitate the separation of the fibre from the wood, and to get rid of the mucilage. To accomplish this, the flax-straw is tied in bundles and placed in ponds or rivers, where it is allowed to remain for a period of eight to twelve days, when it is taken out, and then undergoes *Grassing*, the bundles being untied and the straw spread out evenly and regularly on pasture land, and frequently turned so as to expose both sides to be washed and bleached by exposure to the rain and sun. Then follows *Breaking*, by which operation the woody part of the stem is broken previous to *Scutching*, which removes all the broken fragments left adhering after the last process. These two operations are generally effected by machinery, but were formerly performed by hand labour. After scutching, flax finds its way into the market, but before being used by the spinner it undergoes a sixth operation called *Hekling*, which removes all extraneous matter and completely separates and arranges the filaments in parallel order. It consists in drawing the flax over sharp iron spikes arranged in a quincunx manner and inserted into oblong pieces of wood.

Besides the fibre of the Flax plant, its oily seeds, known as Linseed, are a commercial article of considerable importance, no less than 1,330,023 quarters having been imported in 1860, principally from Russia and India, for the supply of our oil-mills. The finest kind of linseed oil is the product of simple pressure, and is called 'cold-drawn'; but the ordinary kind is obtained

by breaking up, beating, and re-pressing the marc or cake left after the last process. It is a non-drying oil, but by boiling with sugar of lead, red-lead, or white vitriol, it is converted into a drying oil fit for the use of painters, by whom it is most extensively employed. The cake is greatly valued by agriculturists for feeding purposes, and in addition to that made in this country, large importations are received from abroad, mainly from the United States. [A. S.]

**LIONDENT.** (Fr.) *Leontodon*.

**LION'S-EAR.** A common name in the Andes for some species of *Culcitium*; also *Espeltia*, and *Leonotis*.

**LION'S-FOOT.** *Leontopodium*; also *Hymenocoma Tournafortii*, *Alchemilla vulgaris*, *Nabalus Fraseri*, and *N. serpentarius*.

**LION'S-LEAF.** *Leontice*, especially *L. Leontopetalon*.

**LION'S-PAW.** *Alchemilla vulgaris*.

**LION'S-TAIL.** *Leonotis Leonurus*.

**LION'S-TOOTH.** *Leontodon*.

**LIPARIA.** A genus of *Leguminosæ* of the suborder *Papilionaceæ* and tribe *Lupartæ*, consisting of South African shrubs, with undivided alternate lanceolate rigid and pungent leaves, and bright yellow flowers in terminal heads. The genus differs from *Priestleya* chiefly in the lowest division of the calyx, which is much larger than the others, being coloured and petal-like. There are three or four species, amongst which *L. sphaerica* is remarkable for the dense nodding flower-heads, fully three or four inches in diameter.

**LIPARIS.** This genus of small-flowered orchids consists of about an equal number of terrestrial and epiphytal herbs, and is distinguished among the malackaceous genera by their four collateral pollen-masses, and by their free lateral sepals, entire lip plane at the base, and elongated semiterete column. One or two are European or North American, but the majority are Indian or Javanese. [T. M.]

**LIPOCHÆTA.** A genus of *Compositæ*, of the tribe *Heliantheæ*, and very nearly allied to the opposite-leaved *Verbesina*, distinguished chiefly by the achenes, which are scarcely winged, those of the ray having usually three angles and short awns, whilst those of the disk have only two and are often abortive. There are about ten species, natives of the Sandwich Islands, and an eleventh from the Galapagos, which has been published under the name of *Marcia*. They are all rough or hoary herbs or undershrubs of little interest or beauty.

**LIPPIA.** A large genus of *Verbenacæ*, containing nearly a hundred species, natives of America. They are herbs or shrubs, generally with glands containing an aromatic volatile oil, simple opposite or verticillate leaves, and small flowers in heads or spikes. The calyx is two or four-

toothed or two-lipped; the corolla strongly two-lipped, with the upper lip notched and the lower much larger and three-lobed; the stamens included; the ovary two-celled surmounted by a capitate stigma. The small capsular fruit is two-celled and two-seeded. [W. C.]

**LIQUIDAMBAR.** A genus of *Altingiaceæ*, consisting of trees, with alternate petiolate stipuled leaves, and unisexual flowers in catkins. The flowers are monocious, surrounded by a four-leaved deciduous involucre; the male catkins conical or subglobular with numerous anthers; the female subglobular, surrounded by scales; ovary two-celled, with numerous ovules, the fruit forming a sort of strobilus. They are natives of North America, Java, and Asia Minor. [J. H. B.]

**LIQUIDAMBAR COPAL.** (Fr.) *Liquidambar styraciflua*. — **À FEUILLES DE CÉTÉRACH.** *Comptonia asplenifolia*. — **DU LEVANT.** *Liquidambar orientale*.

**LIQUIRITIA.** *Glycyrrhiza*.

**LIQUOR AMNIO.** The fluid that is contained in the sac within which the embryo is engendered.

**LIQUORICE.** *Glycyrrhiza glabra*. — **WILD.** *Abrus*; also an American name for *Gallium circæans*.

**LIRELLA.** A linear shield with a furrow along its middle, in such lichens as *Opegrapha*.

**LIRICONFANCY.** *Convallaria majalis*.

**LIRIODENDRON.** A name derived from the Greek words signifying Lily-tree, and applied to a genus of *Magnoliacæ*, the only representative of which is the well-known Tulip-tree of North America. This tree attains a height of 140 feet in America,

*Liriodendron tulipifera*.

and of 50 to 100 feet in this country. The bark is smooth, the leaves large, bright green, truncate at the point, four-lobed and somewhat like a saddle in shape; hence the tree is sometimes spoken of as the

**Saddle-tree.** The stipules are large, opposite, flat, and serve the function of scales to the young buds, which are bent downwards, becoming subsequently erect, when the stipules fall off. The flowers are large, somewhat like a tulip in appearance; they have a calyx of three deciduous segments which are turned down, and a corolla of six erect petals forming a kind of cup of bell, and both sepals and petals are greenish variegated with yellow and orange. The fruits of the Tulip-tree do not split when ripe, as those of *Magnolia* do.

The noble appearance of this tree renders it a great favourite in English pleasure grounds, but the flowers are not produced until it has attained an age of from twenty to thirty years. In America the wood, which is yellow or whitish according to age, is employed by the Indians in the construction of their canoes, for which purpose its lightness renders it available. It is likewise used by cabinet-makers, and by coach-builders for the panels of coaches, &c. The tree shares in the bitter tonic principle common to most of the trees of the *Magnoliaceae* family. The foliage of the Tulip-tree assumes in autumn an intensely bright golden yellow hue. [M. T. M.]

**LIRIOSMA.** A genus of *Oleaceae*, consisting of a Brazilian tree with soft yellow odoriferous wood, alternate elliptical glabrous leaves, and axillary flower-panicles shorter than the leaves. The flowers have a calyx adherent to the ovary, with a truncate tube and nine stamens, of which six are sterile, petaloid, and blind. [J. T. S.]

**LIL.** (Fr.) *Lilium candidum*. — ASPHODELE. *Hemerocallis flava*. — D'ANGLETERRE. *Iris zephyroides*. — DE GUERNESEY. *Nerine carolinensis*. — DE MAI. *Convallaria majalis*. — DE PORTUGAL. *Iris zephyroides*. — DE SAINT BRUNO. *Anthericum Liliastrium*. — DE SAINT JACQUES. *Amaryllis* or *Sprekelia formosissima*. — DES ALLOBROGES. *Anthericum Liliastrium*. — DES INCAS. *Alströmertia Pelegrina*. — DESPAGNE. *Iris zephyroides*. — D'ÉTANG. *Nymphaea alba*. — DES VAL-LEES. *Convallaria majalis*. — ISABELLE. *Lilium testaceum*. — JACINTHE. *Scilla italica*. — JAUNE. *Hemerocallis flava*. — JAUNE DORÉ. *Lycoris aurea*. — MATRIOLLE. *Pancratium maritimum*. — NARCISSE. *Pancratium maritimum*; also *is bulbosa*. — TURBAN. *Lilium*

**LISERÉ.** (Fr.) *Convolvulus arvensis*.

**LISERON.** (Fr.) *Convolvulus*. — DE MICHAUX. *Pharbitis hederacea*. — DE PORTUGAL. *Convolvulus tricolor*. — DES HAÏES. *Calystegia septium*. — ÉPINEUX. *Smilax aspera*. — GRAND. *Calystegia septium*. — NOIR. *Polygonum Convolvulus*. — PETIT. *Convolvulus arvensis*. — SATINÉ. *Convolvulus Onocrium*.

**LISÉ.** (Fr.) *Convolvulus arvensis*. — PIQUANT. *Smilax aspera*.

**LISIANTHUS.** A genus of *Gentianaceae*, consisting of tropical American herbs or

undershrubs, with decussate sessile or stalked ribbed leaves. The flowers are more or less clustered, axillary or terminal; the calyx bell-shaped, with five erect segments, membranous at their edges; the corolla funnel-shaped, purple red blue or yellowish-green in colour, withering on the plant, its tube slightly irregular; the stamens five, within the corolla, the anthers ultimately rolled back; the capsule two-celled.

The flowers of *L. Russellianus* are very handsome; while those of *L. princeps* are described as constituting the plant one of the noblest in existence. It is a greenhouse shrub with long hanging flowers of a rich scarlet melting into yellow at either end, and having an emerald green five-lobed limb. [M. T. M.]

**LISSANTHE.** A genus of *Epicurideae*, entirely confined to Australia and Tasmania. They are small rigid shrubs, sometimes not more than three or four inches high, and seldom exceeding five or six feet, having small scattered sharp-pointed often needle-shaped leaves, and very small usually white flowers, borne either singly or in short spikes from the sides of the branches. The corolla is funnel-shaped, destitute of the hairs upon the limb possessed by its congeners, whence the generic name from *lissos*, smooth, and *anthos*, a flower. The fruit is a small fleshy berry containing a hard stone. That of several species is eatable. *L. sapida*, a native of South-eastern Australia, is called the Australian Cranberry on account of its resemblance both in size and colour to our European cranberry, but its flesh is thin, and more like that of the Siberian crab. *L. strigosa* and *L. montana* are eaten in Tasmania, the latter being a very dwarf mountain species bearing large white transparent fleshy fruits. [A. B.]

**LISSOCHILUS.** A genus of vandeous African orchids, of terrestrial habit, with striated or plicate leaves, and racemes of rather showy flowers springing from the base of the pseudobulbs. It comes near *Eulophia*, but is distinguished by the great disproportion between sepals and petals. The sepals are small, reflexed or spreading; the petals large, spreading, wing-like; the lip sacrate; the column short, erect; and the pollen-masses two in number, bilobed behind, with a short linear caudicle, and a triangular gland. The species are not very numerous. [T. M.]

**LISTERA.** A genus of terrestrial orchids, consisting of slender herbs with a rootstock bearing a mass of thickish fibres, and two leaves at some distance from the ground, and so near together as to appear opposite. The flowers are small, green, in a slender raceme; the sepals and petals nearly alike, short and spreading; the lip longer, linear, and two-cleft; there is no spur; and the anther is fixed by its base in a cavity at the top of the short column. There are but few species, natives of Europe, Northern Asia, or North America,

Two are British: *L. ovata*, the common Tway-blade, which has a stem often above a foot high, and broadly ovate leaves two to four inches long; and *L. cordata*, a more northern mountain plant, seldom above six inches high, with the leaves small, and usually slightly cordate.

**LITANTHER.** A genus of *Liliaceæ*, from the Cape of Good Hope. An extremely small herb, with a bulb almost the size of a pea, a bristle-like scape appearing before the leaves, and a single small drooping flower, with a greenish-white tubular cylindrical perianth, having a six-cleft limb, and six included stamens. [J. T. S.]

**LITCHI.** The fruit of *Nephelium Litchi*, a plant sometimes referred to *Euphoria* or *Dinocarpus*.

**LITHOCARPUS.** A genus of *Cupulifereæ*, consisting of lofty trees with alternate entire leaves, and monœcious flowers in caskins. The male caskins are filiform, with a cup-shaped six-cleft perianth, and twelve to twenty stamens inserted at its base; while the female flowers are sessile on a common rachis, surrounded by scales. The fruit is a hard nut, enclosed in scales. *L. javanica* is the only species. [J. H. B.]

**LITHOSPERMUM.** The Gromwell genus, a large group of *Boraginaceæ*, known by having the corolla regular, funnel-shaped or salver-shaped, without scales at the throat, where are often five plates; and by the nuts not being contracted at the base, and having a flat surface of adhesion to the receptacle. The species are generally distributed, but most numerous in the warmer parts of the temperate zone. They are rough strigosely hairy herbs or undershrubs, with bracteated racemes of purple, blue, white, or yellow flowers. [J. T. S.]

**LITHOXYLON.** A genus of *Euphorbiaceæ*, established by Endlicher for the *Securinega nitida*, an Otahaitian plant, differing in some slight particulars from the rest of that genus.

**LITHY-TREE.** *Viburnum Lantana*.

**LITMUS.** A blue dye prepared from *Rocella tinctoria* and some other lichens, by incineration and occasional agitation in a mixture of urine, lime, and potash. A kind of fermentation takes place, and the lichen becomes first reddish, and then blue. When dried it has, if rubbed with the nail, a coppery tint like indigo. Litmus is of great importance to chemists, as it affords a delicate test for acids and alkalies, since blue litmus acquires from acids a red tint, which is restored by alkalies. For this purpose paper is steeped in a solution of litmus, and then dried and bound up in packets; when so prepared, it is sold under the name of test-paper. [M. J. B.]

**LITOBROCHIA.** A genus of pteroid ferns, closely allied indeed to *Pteris* itself, from which it is separated by the reticulation of the veins of the fronds. From *Amphidictya*, another reticulated genus of *Pteridæ*, it is known by the absence of

free veinlets from the areoles; while *Lonchitis*, which also agrees with it in this particular, is known by its sori being for the most part confined to the sinuses of the segments, whence it takes a lunate form, those of *Litobrochia* being continuous along the whole margin of the segments. The group *Doryopteris*, with simple or palmate fronds, which is sometimes separated as a distinct genus, has the veins hidden in the substance of the fronds; while in true *Litobrochia* the fronds are once, twice, or thrice pinnate, and the veins are more distinctly visible. They are nearly all of them natives of tropical climates, and are found in considerable numbers in both hemispheres. [T. M.]

**LITSEA.** A genus of Indian trees of the laurel family, with reticulated leaves and flowers in axillary tufts, protected by numerous overlapping scales which fall off after a time. The flowers are unisexual, both males and females having a four to six-parted deciduous perianth: the former with six stamens having four-celled anthers, and some of the stamens glandular at the base; the latter with four or six sterile stamens, and a number of glands surrounding the ovary. The fruit is fleshy, and placed upon the thickened top of the flower-stalk. [M. T. M.]

**LITTEA.** Under this name Tagliabue, an Italian botanist, described a South American *Agave*, which flowered for the first time in Europe in the garden of the Duke of Litta, near Milan, in 1815; but which now bears the name of *Agave geminiflora*. It has a short stout trunk, bearing on its summit a dense crowd of narrow whip-like dull-green leaves, from the midst of which, once in the lifetime of the plant, rises a straight spear-like stem, twenty or more feet high, bearing an immense number of yellowish-green flowers, with long protruding stamens furnished with versatile anthers. [A. S.]

**LITTLEGOOD.** *Euphorbia helioscopia*.

**LITTORAL.** Growing on the sea-shore.

**LITTORELLA.** An herbaceous perennial belonging to the *Plantaginaceæ*, common on the margins of the English and Scottish lakes, where it forms a turf. The leaves, all of which proceed directly from the roots, are grass-like but fleshy; and the flowers are some barren and some fertile, the latter sessile among the leaves, the former elevated in scapes two or three inches high, and remarkable for their four long slender filaments and tremulous anthers. *L. lacustris*, commonly called Shore-weed, is the only species. [C. A. J.]

**LITUATE.** Forked, with the points a little turned outwards.

**LITURATE.** When spots are formed by the abrasion of the surface.

**LIVÈCHE.** (Fr.) *Levisticum*.

**LIVELONG, or LIVE-FOR-EVER.** *Sedum Telephium*.

**LIVER-LEAF.** *Hepatica.*

**LIVERWORT.** *Marchantia polymorpha.* —, **GROUND.** The herbalists' name for *Peltidea canina*, Dr. Mead's once celebrated remedy for hydrophobia. —, **NOBLE.** *Hepatica triloba.*

**LIVERWORTS.** Lindley's name for the *Marchantiaceae*.

**LIVID.** Clouded with intermingled greyish brownish and bluish tints.

**LIVISTONA.** The geographical range of this genus of palms extends from Upper Assam and Southern China, through Malacca and the islands of the Indian Archipelago, to the continent of Australia, reaching as far south as the colony of Victoria. Of the eight or ten known species, two are noble trees attaining the height of eighty or a hundred feet, while the others seldom exceed twenty or thirty feet. Their leaves are terminal and fan-shaped, divided into numerous segments, which are split at the apex; and frequently have threads hanging between them, while the footstalks are sheathed at the base in a mass of netted fibres, and are often prickly along the edges. Their branching flower-spikes grow out from amongst the leaves, and have several incomplete leathery spathe surrounding their stalks. The flowers have a three-cut calyx, and a three-parted corolla, and are all perfect. The fruits are dry and one-seeded.

*L. australis*, also called *Corypha australis*, is one of the few palms belonging to the Australian continent, and is principally found along the east coast to as far as latitude 37° S. It is the tallest of the species, occasionally attaining upwards of a hundred feet in height, with a trunk about a foot in diameter. Its unexpanded leaves, prepared by being scalded and then dried in the shade, are used for making hats; while the still younger and more tender leaves are eaten like cabbages. In Assam the leaves of *L. Jenkinsiana*, the Toko Pat of the natives, are used for making the peculiar umbrella hats worn in that country, and also for thatching roofs, &c. [A. S.]

**LIZARD'S HERB.** *Goniophlebium trilobum.*

**LIZARD'S TAIL.** *Saururus.*

**LIZARD'S TONGUE.** *Saururus cuneatus.*

**LLAVEA.** A very interesting genus of polypodiaceous ferns, belonging to the section *Platyloperis*, and sometimes known by the name *Ceratodactylis*. The only species, *L. cordifolia*, has tripinnate glaucous fronds, the lower parts of which have broadly cordate-ovate sterile pinnules, and the upper parts long linear siliquiform fertile ones, forming a marked contrast to each other. The sori are in simple or forked contiguous lines near the ends of the free veins, the frond-margin being somewhat revolute and attenuated, so as to become a spurious indusium. The plant is Mexican, and is found at considerable elevations. [T. M.]

**LLITHI, or LITHRI.** *Lithos caustica.*

**LLOYDIA.** A liliaceous plant, from five to six inches high, with flowers composed of six nearly equal spreading persistent petals, or rather sepals, which are white, veined with red or green; stamens not bearded, the anthers and style erect. 'The flower-stalk is invested with its own sheath, and separated by an elongation of the root from the leaves, of which the most distant encloses within its fleshy base the rudiment of the plant of the following season. The plant is increased by offsets or creeping shoots with a bulb at the extremity, the point of the bulb being directed towards the parent root.' *L. serotina* was named in honour of Mr. Edward Lloyd, who first discovered the plant on the higher mountains of North Wales. [C. A. J.]

**LOASACEÆ.** (*Loasacæ, Loasacæ*.) A natural order of dicotyledonous plants belonging to Lindley's natural alliance of epigynous Exogens. Herbs with rigid or stinging hairs, opposite or alternate exstipulate leaves, and showy flowers. Calyx adherent; limb four to five-parted; petals five or ten, often hooded; stamens numerous, distinct or united in bundles; ovary one-celled, with several parietal placentas; style single. Fruit capsular or succulent; seeds albuminous. American plants, some of which from their stinging qualities are called Chili Nettles. There are about a score of genera, of which *Loasa* is the best known. [J. H. B.]

**LOASA.** The typical genus of *Loasacæ*, and one of those having ten petals in a double series, the five inner or smaller of which in this case are furnished with three bristles on their backs. It is best distinguished from the allied ten-petaled genera by its triad stigma, with acute conniving lobes; and by its capsules opening by three valves at their shortly exserted summits. All the species belong to the cool regions of Peru and Chili, and thrive in the open air during summer in this country, several being grown in our gardens on account of their conspicuous yellow or orange flowers. Many are furnished with bristly hairs secreting an acrid fluid, and inflict a sharp sting when incautiously handled. [A. S.]

**LOBBIA.** A genus of *Aristolochiaceæ*, named after Mr. Lobb, a botanical traveller, and comprising a climbing pepper-like shrub, with wavy knotted branches, stalked leaves without stipules, and pendulous spikes of flowers placed on a thread-like four-sided receptacle. The perianth is brownish-red, bell-shaped, with a three-lobed limb, the tube having a prominent rim running round the interior; stamens sixteen to eighteen, inserted on a disk surmounting the ovary, and united with the base of the style, the filaments free; ovary inferior, linear, four-celled. The shrub is a native of Singapore. [M. T. M.]

**LOBEBERRY.** A common name for *Coccoloba*.

**LOBELIACEÆ. (*Lobeliads*.)** A natural order of dicotyledonous plants, belonging to Lindley's campanul alliance of epigynous Exogens. Milky herbs or shrubs with alternate exstipulate leaves; calyx superior, its limb often five-lobed; corolla irregularly five-lobed, often deeply cleft; stamens epigynous, the anthers united; stigma fringed. Fruit capsular, one or more celled, opening at the top; seeds numerous, with albumen. Found chiefly in tropical and subtropical climates. Acid and narcotic qualities prevail in the order, which contains about twenty-nine genera, and nearly four hundred species. Examples: *Lobelia*, *Siphocampylus*. [J. H. B.]

**LOBELIA.** This genus commemorates Matthew Lobel, a physician and botanist of the seventeenth century, who was attached to the court of James I. It also forms the typical genus of *Lobeliaceæ*, and consists of a large number of herbaceous plants, widely distributed over the tropical and subtropical regions of the globe, especially in America, less abundantly found in Northern Europe and Asia. In general habit the species vary much, but are more constant in the characters presented by the flowers, which have a five-lobed calyx with a variously-shaped tube; a corolla whose tube is slit along the upper side, and whose limb is divided into two lips, the upper of two, the lower of three divisions; anthers united into a tube round the style, two, or sometimes all of them, hairy at the top; and an ovary more or less adherent to the calyx.

As is very frequently the case with milky-juiced plants, some of the species of this genus have acrid properties. Such are *L. cardinalis*, *L. siphilitica*, and especially *L. inflata*, a North American plant, sometimes called Indian Tobacco, the symptoms to which it gives rise, as well as its flavour, being not unlike those of tobacco. Given in small doses it operates as a diaphoretic and expectorant, in larger ones as an emetic, while in excessive doses it acts as a powerful acrid narcotic poison, causing great prostration, convulsions, and death. Serious results have followed the injudicious administration of this drug by so-called 'medical botanists,' who deny that the plant is a poison. In medicinal doses, the drug has been, and still is, occasionally used in spasmodic asthma with advantage.

Numerous species of this genus are cultivated in English gardens for the splendour of their flowers, among which *L. cardinalis*, *L. splendens*, and *L. fulgens* are especially conspicuous. Several varieties of these species are now cultivated, the flowers of which present every shade of scarlet, purple, and blue. *L. Erinus* is a low-growing trailing plant, with small pale blue flowers, much used as a bedding plant. Two species are British: *L. Dortmanna*, found in shallow lakes, and *L. urens*, which grows in heathy places. [M. T. M.]

**LOBESTENS.** The fruits of *Cordia Myxa* and *latifolia*.

**LOBIOLE.** One of the small lobes into which the thallus of some lichens is divided.

**LOBULE.** A small lobe. Thus *lobulate* means divided into small lobes.

**LOBLOLLY WOOD.** The wood of *Ocupania glabra*; also of *Pisonia cordata*.

**LOBLOLLY SWEETWOOD.** A West Indian tree for *Sciadophyllum Jacquinii*.

**LOBOCARPUS.** A little-known genus described by Wight and Arnott as belonging to *Anonaceæ*. More recent investigations, however, show that it must be referred to *Eschschoriaceæ*; and Müller suggests that it may be a species of *Glochidion*. It is a native of the Indian peninsula. [J. Br.]

**LOCELLI, LOCELL.** The peridia of certain fungals.

**LOCELLUS.** A secondary cell; a small cell within a larger.

**LOCHERIA.** One of the subgenera of *Achimenes*, consisting of erect herbs with axillary or subpaniculate flowers, the peculiar features of which are an oblique funnel-shaped corolla much larger than the calyx, a nearly entire five-angled fleshy ring round the ovary, and a two-cleft stigma. *A. hirsuta* and *podunculata* are illustrations. [T. M.]

**LOCLATE, LOCULAR.** Divided into cells.

**LOCLUS, LOCLAMENTUM.** A cell or cavity. Usually the cell of a fruit or ovary; that is to say, the cavity of one or more carpels. Also the peritheciium of certain fungals.

**LOCLICIDAL.** That mode of dehiscence which consists in ripened carpels splitting or dehiscing through their backs.

**LOCTLOSE.** Divided by internal partitions into cells, as the pith of the walnut-tree. This is never applied to fruits.

**LOCUSTA.** A spikelet of grasses; that is to say, one of the collections of florets formed in such plants.

**LOCUST-BERRY.** *Malpighia coriacea*.

**LOCUST-TREE.** *Ceratonia Siliqua*; also *Robinia Pseud-Acacia*. —, **BASTARD.** *Clethra tinifolia*. —, **HONEY.** *Gleditschia triacanthos*. —, **SWAMP or WATER.** *Gleditschia monosperma*. —, **WEST INDIAN.** *Hymenaea Courbaril*; also *Byrsonima coriacea* and *cineria*.

**LODDIGESIA.** A small glabrous undershrub with trifoliate leaves, and small purple and white flowers in short terminal racemes. It is a native of the Cape, and forms of itself a genus of *Leguminosæ* in the section *Papilionaceæ*, nearly allied to *Hypocalyptus*, but differing chiefly in the very short vexillum or upper petal and in the very flat ovate acute pod. It is a rather pretty species, and has been in cultivation, though now apparently abandoned.

**LORIOULE.** The hypogynous scale of a grass.

**LOBOICHA.** Prior to the discovery in 1748 of the Seychelles Islands, the existence of the palm, *L. sechellarum*, upon which this genus is founded, was unknown, but its immense woody nuts were frequently found floating upon the sea, or were thrown up on the shores of the Maldivé Islands, and gave rise to many absurd fabulous tales. It was called the Double Cocoa-nut Palm, Coco de Mer, or Coco des Maldives. The tree has a nearly cylindrical trunk, scarcely exceeding a foot in diameter, and bearing a crown of large fan-shaped leaves, some of which are upwards of twenty feet long, and twelve feet wide. They are of two sexes, both of which have three sepals and three petals to the flowers, those of the females being large, thick, and fleshy. The fruits externally are covered with a thick fibrous husk, and contain usually one, but sometimes two or even three immense stones or nuts with excessively hard and thick black shells, each being divided half-way down into two lobes, whence the popular name.

In olden times important medicinal virtues were attributed to these nuts, water drunk out of vessels made of them being supposed to preserve people from all complaints, and extravagant prices were consequently paid for them. At the present day they are converted into various domestic utensils, while the wood serves many useful purposes, and the leaves are made into hats and beautiful baskets, cigar-cases, &c., besides being used for thatching. [A. S.]

This magnificent palm, which is found only in two small islands, Praslin and Curieuse, belonging to the Seychelles group, requires a great length of time to arrive at maturity. The shortest period before it puts forth its flower-buds is thirty years, and a hundred years elapse before it attains its full growth. From the age of fifteen to twenty-five years it is in its greatest beauty, the leaves at this period being much larger than they are subsequently. The stem grows quite upright, straight as an iron pillar, and in the male trees frequently attains a hundred feet in height, the females being shorter. At the age of thirty it first puts forth its blossoms, the males forming enormous catkins about three feet in length and three inches in diameter, while the females are set on a strong zigzag stalk, from which hang four or five, or sometimes as many as eleven nuts, averaging about 40 lbs. weight each. From the time of flowering to the maturation of the fruit, a period of nearly ten years elapses, the fullsize, however, being attained in about four years, at which time it is soft and full of a semi-transparent jelly-like substance. The apparently peculiar formation of the root portion of this tree attracted much attention a few years since, but upon comparison with other palms it seems to be explained as an extraordinary development of a common system. The base of the stem is

rounded and fits into a natural bowl or socket, which is pierced with hundreds of small oval holes about the size of a thimble, with hollow tubes corresponding on the outside, through which the roots penetrate the ground on all sides, never however becoming attached to the bowl, their partial elasticity affording an almost imperceptible but very necessary 'play' to the parent stem when struggling against the force of violent gales. This bowl is of the same substance as the shell of the nut, only much thicker; it rots very slowly, for it has been found quite perfect and entire in every respect sixty years after the tree has been cut down. The reprehensible practice of destroying the trees for the sake of their nuts will, it is to be feared, lead to the extinction of the Coco de Mer, which will become in reality as rare as it was supposed to be by the voyagers who picked up the first known specimens of its nuts floating on the sea. [T. M.]

**LOEFLINGIA.** A small genus of *Ilcebraceæ*, consisting of small annuals from the Mediterranean region and California. They have awl-shaped opposite leaves, bristle-like half-adhering stipules, and very small sessile flowers in pairs or threes in the axils of the leaves and the forks of the dichotomous branches, forming small dense fasciculate cymes. [J. T. S.]

**LOGANIACEÆ.** (*Spigeliaceæ*, *Strychnæ*, *Potaliaceæ*, *Cælostylacæ*, *Loganiadæ*.) A natural order of dicotyledonous plants, belonging to Lindley's gentianial alliance of perigynous Exogens. Herbs, shrubs, or trees, furnished with opposite entire stipulate leaves; calyx inferior, four to five-parted; corolla four, five, or ten-cleft, with convolute or valvate aestivation; stamens varying in number, not always equal to the parts of the corolla. Fruit a two-celled capsule with loose placentas, or a berry, or succulent with one or two nucles; seeds usually peltate, with albumen. They inhabit chiefly tropical and warm countries. The plants are bitter and highly poisonous. The poison-nut, *Strychnos nuxvomica*, belongs to the order. There are upwards of thirty genera and nearly two hundred species. Examples: *Logania*, *Spigelia*, and *Strychnos*. [J. H. B.]

**LOGANIA.** A genus of *Monopetalæ* which has given its name to the order *Loganiaceæ*. It consists of fifteen or sixteen Australian species, and one from New Zealand, all herbs or small shrubs, with opposite entire leaves, and small flowers in axillary or terminal cymes or panicles. In botanical characters they differ chiefly from *Buddleia* (by some referred to *Scrophulariaceæ*) in the parts of the flower being usually in fives instead of in fours, in foliage and habit, and in the absence of that stellate down or tomentum so universal in *Buddleia*. None of the species are of any particular interest either as useful or ornamental plants.

**LOGGERHEADS.** *Centaurus nigra*.

**LOGWOOD.** The wood of *Hæmatoxylon*

*campechianum*. —, BASTARD. *Acacia*  
*Berteriana*. —, WEST INDIAN. *Ceano-*  
*thus Chlorocylon*.

**LOISELEURIA.** A genus of *Ericaceae*, the only species of which, *L. procumbens*, is sometimes called *Azalea procumbens*. It is a low trailing evergreen shrub, with small opposite ovate or oblong leaves, and small rose-coloured flowers in terminal clusters, these having a calyx of five sepals, a campanulate five-lobed corolla, and a capsule with two or three cells containing several seeds. It is found on mountain moors in the northern parts of Europe, Asia, and America, and in our own country on the Scottish Highlands. [T. M.]

**LOLIUM.** A genus of grasses belonging to the tribe *Hordeae*, distinguished chiefly by the inflorescence being in close spikes, with the solitary spikelets placed edgewise along the rachis; glumes solitary, or with that next the rachis very minute, having three or more flowers. The Ray or Rye Grasses are among the most valuable species cultivated in Britain, alike useful as parts of a mixture of grass seeds for sowing on land intended for permanent pasture, and for growing singly as crops in alternate husbandry cultivation. *L. perenne* and the variety called *L. italicum* are the best kinds, especially the latter, which is now extensively grown in all districts where good farming is carried on. By proper management the first crop may be ready for cutting in April, and three more cuttings of after-grass during the season. One of the few deleterious grasses is *L. temulentum*, or Darnel, which sometimes

*Lolium temulentum*.

prevails to a dangerous extent among white crops, particularly wheat. When ground up with the corn and made into bread, it is said to produce poisonous effects on the system, such as headache, drowsiness, vertigo, &c. [D. M.]

**LOLO.** The name in some parts of the Pacific for cocoa-nut oil.

**LOMAGRAMMA.** A genus of ferns of the section *Tantitides*, found in the Philippine Islands. They have pinnate fronds, with the pinnae articulated, and the fertile ones contracted, the venation uniformly reticulated, and the fructification forming non-indusiate linear continuous marginal lines of spore-cases. There is only one species described. [T. M.]

**LOMANDRA.** *Xerotes*.

**LOMARIA.** An extensive genus of polypodiaceous ferns typical of the section *Lomarietæ*. They are various in size and character, but agree in having free veins, with linear continuous sori, on a broadish linear receptacle occupying nearly the whole under surface of the contracted fertile fronds. The indusium is marginal, opening on the inner side, while from the contraction of the parts the sorus is costal, that is, close to the midrib. They are closely allied to *Blechnum*, with which indeed some botanists propose to unite them, the most marked distinction being the marginal sori of *Lomaria* as opposed to the evidently intramarginal sori of *Blechnum*. *Lomaria* always has contracted fertile fronds, while those of *Blechnum* are generally not at all contracted, but this is not an absolute distinction. The species occur in most parts of the world, and comprise examples with simple pinnatifid and pinnate fronds, while one species, *L. Fraseri*, has a slender tree-like caudex and bipinnatifid fronds, but it is quite exceptional in the genus. The close affinity between *Lomaria* and *Blechnum* is indicated by the fact that our native *Blechnum Spicant* is frequently included in the former genus. [T. M.]

**LOMARIOPSIS.** A genus of acrostichoid ferns having altogether the aspect of *Lomaria*, that is to say, bearing coarse pinnate fronds, the fertile ones contracted; but differing in the spore-cases occupying the whole under surface of the fronds instead of being confined to the margin, and in the absence of a true indusium. They are mostly scandent ferns, climbing up the trees of tropical forests, both in the Old and New World. [T. M.]

**LOMATIA.** A genus of *Proteaceae*, consisting of shrubs or small trees, natives of extra-tropical Australia, Tasmania, and South-west America. They have simple pinnate or bipinnate leaves, generally toothed, and of a leathery texture; and flowers of a brownish-yellow colour, occasionally red, and having an irregular spreading calyx of four sepals, four sessile anthers, and a siltform style with an oblique dilated stigma. The seed-vessel is an ovate two-valved leathery follicle, containing several partially winged seeds. [R. H.]

**LOMATOPHYLLUM.** A genus of *Ericaceae* from the Isle of Bourbon, allied to *Aloë* and *Jucca*, having a tubular corolla like the former, but differing in the fruit, which

is not membranous, but soft and leathery; also in the seeds, which have a thick black seed-coat. From *Yucca* it is known by the perianth not having the leaves all separate. It has an arborescent stem or caudex, with the leaves collected at the top, elongate-lanceolate, with cartilaginous spiny-scabrate margins, and axillary peduncles bearing paniculate flowers. [J. T. B.]

**LOMENTACEÆ.** A suborder of *Cruciferae* characterised by the siliqua or pod being lomentaceous, that is, having complete transverse partitions separating each seed from those next to it. Sometimes the true siliqua is barren, and the seeds are placed in the partitioned beak of the pod. Among British plants this suborder is represented by *Cakile maritima*, *Crambe maritima*, *Raphanus Raphanistrum*, and *R. maritimus*. [J. H. B.]

**LOMENTUM** (adj. **LOMENTACEOUS**). An indehiscent legume, which separates spontaneously by a transverse articulation between each seed.

**LONGCHITIS.** A pteroid genus of ferns, having large herbaceous twice or thrice pinnate fronds, and a thick short rhizome, the fructification forming marginal indurated lines as in *Pteris*, but differing in being of a lunate figure from their occupying the rounded sinuses between the segments rather than the margins of the segments themselves. This is the prevailing character, but occasionally the sort are extended up the sides of the segments. They occur in the Mauritius, Madagascar, the Cape, and South America. [T. M.]

**LONGCHOCARPUS.** An extensive genus of Leguminous plants, of which the greater number are tropical American, seven tropical African, and one Australian. Some are small trees, seldom exceeding thirty or forty feet in height, and others tall climbing shrubs with woody stems. They have alternate pinnate leaves, except in a solitary species from Southern Mexico, in which they are reduced to a single leaflet; and their pea-like flowers are in racemes and either purple reddish or white, but never yellow. The genus is solely distinguished from its congeners by its pods, the structure of its flowers not differing from that of *Pisicidia* and other allied genera. The pod is flat, much longer than broad, varying from a thin paper-like to a hard woody consistency, and without wings along the edges, the seed-bearing edge being merely thickened or flattened.

The leaves and young branches of several species of this genus are employed by the Indians of South America for poisoning fish, or rather for intoxicating them, so that they float upon the surface of the water in an insensible state, and are thus captured, but afterwards recover and are good food. One species used for this purpose by the Indians of Guiana was called *Nicon*—its Indian name, but it now bears the name of *L. rupestris*. [A. S.]

**LONGICOSTOMA.** A genus of the hy-

drophyllaceous order, having the border of the corolla in five lanceolate divisions; and the styles two, and shorter than the tube of the corolla. The species are Cape shrubs, with alternate entire ovate leaves; the flowers solitary in the axils of the upper leaves. [G. D.]

**LONDESIA.** A genus of *Chenopodiaceae* from the eastern shore of the Caspian Sea. *L. eriantha* is a branched annual covered with white wool; the leaves alternate, oblong or lanceolate, entire; and the flowers on short axillary branches, in involucre bracteated small globose heads: they are polygamous, the females more abundant than the perfect ones. [J. T. S.]

**LONDON PRIDE.** *Su. 'nqa umbrosa*.

**LONGAN, or LONG-YEN.** The fruit of *Nephelium Longanum*.

**LONG-BEARD.** *Tillandsia usneoides*.

**LONG-GLAND.** *Macradenia*.

**LONGITUDO.** In the direction of growth.

**LONG-PURPLE.** Shakspeare's name for *Orchis mascula*.

**LONGICERA.** An extensive genus of climbing or upright shrubs inhabiting both eastern and western hemispheres, and much cultivated for the sake of ornament and the fragrance of their flowers. The genus is by some botanists divided into two subgenera, *Caprifolium* and *Xylosteum*. In its widest extent it includes all plants belonging to the order *Caprifoliaceae* marked by the following characters: Calyx small, five-toothed; corolla tubular, five-cleft, generally irregular; stamens five; style filiform; stigma capitate; ovary one to three-celled, few-seeded. *L. Periclymenum*, the common Honeysuckle, the Woodbine of Shakspeare, the twisted *Eglantine* of Milton, is too well known to need any description, though it may be noticed in passing that the varieties with red and yellow buds are both of the same species. *L. Caprifolium* is distinguished from the preceding by having the upper pairs of leaves united at the base so as to form a cup. These two species have red berries which are glutinous and sweet, but unpalatable. The latter is sometimes found apparently wild, but is not considered to be a true native. *L. Xylosteum* bears its flowers in pairs, and has an upright mode of growth. It is indigenous to Britain, but of unusual occurrence. Besides these, many foreign species are described by botanists, of which *L. sempervirens*, Trumpet Honeysuckle, a handsome climbing species with evergreen foliage and scarlet flowers, is a native of North America; *L. struca* has orange-coloured flowers; and *L. japonica*, so often figured in Chinese drawings, has evergreen foliage and orange-coloured flowers in terminal pairs. By some botanists the genus *Lonicea* is limited to those Honeysuckles which have upright stems, the climbers being placed in the genus *Caprifolium*, *Fr. Chevreulii*; Ger. *Geleblatt*. [G. A. J.]

**LONTAR.** The Palmyra Palm, *Borassus Akebiliformis*.

**LOODE.** An Indian name for *Symplocos racemosa* or *laurina*, the bark of which forms a mordant for red dyes.

**LOOP.** *Luffa aegyptiaca*, the interior netted fibres of which are used in Turkish baths as flesh-rubbers.

**LOOKING-GLASS TREE.** *Heritiera*.

**LOOSESTRIFE.** *Lysimachia*. —, COMMON. *Lythrum Salicaria*. —, FALSE. *Ludwigia*. —, SWAMP. *Decodon*. —, TUFTED. *Naumburgia*. —, WEST-INDIAN. *Jussiaea suffruticosa*.

**LOPEZIA.** A genus of annuals belonging to the *Onagraceae*, and distinguished by having two filaments, of which one bears an anther, the other is petal-like and abortive; the seed-vessel is four-valved, four-celled, many-seeded. There are several species, all natives of Mexico, bearing alternate rarely opposite toothed leaves, and terminal racemes of small purple or red flowers. [C. A. J.]

**LOPHANTHERA.** The name of two Brazilian trees, constituting a genus of *Meliphiaceae*. The leaves are opposite, with two stipules combined into one long axillary scale. The stamens are double the number of the petals, their anthers surmounted by a crestlike appendage; and the fruit is stalked, smooth, not winged, and divided into three lobes, each of which divides into two pieces. [M. T. M.]

**LOPHANTHUS.** A genus of the labiate order, distinguished by having the tube of the corolla as long as the calyx, its upper lip slightly notched, the lower having its middle lobe broad, with prominent convex divisions on its edge. The species are herbaceous, natives of North America and Eastern Siberia. The name is from the Greek words signifying crest and flower, to indicate the peculiar character of the corolla. [G. D.]

**LOPHIOLA.** A genus of the group *Wachendorferae*, which is sometimes referred to the *Liliaceae*, but more usually to *Hamadoraceae*. It is a slender perennial, found in the warmer parts of the United States, with creeping rootstocks, narrow equitant root-leaves, and flowers in a crowded cyme at the top of a leafless scape, the upper part of which and the exterior of the yellowish perianth are densely woolly. The perianth is deeply six-cleft, with spreading divisions. [J. T. B.]

**LOPHIRACEAE, LOPHIRA.** A natural order and genus of dicotyledonous plants belonging to Lindley's guttiferous alliance of hypogynous *Exogena*. Branching trees with alternate entire stipulate leaves, jointed petioles, and pinnated regular yellow flowers with jointed pedicels. Sepals five, the three inner smaller, the two outer becoming expanded like wings; petals five, twisted in aestivation; stamens numerous, the filaments short, and the anthers

adnate; disk none; ovary conical, one-celled; ovules numerous on a free basal placenta; stigmas two. Fruit a coriaceous nut, spindle-shaped, one-celled, one-seeded. Trees from tropical Africa. There is only one known genus, viz. *Lophira*. [J. H. B.]

**LOPHODIUM.** *Lastrea*.

**LOPHOGYNE.** The name of a genus of Brazilian *Podostemaceae*, having the appearance of liverworts or mosses. It would seem as though they had no true stem or leaves, but in their place a frond or thallus variously divided, on which are placed at irregular intervals the flowers, supported by little nerves or bundles of cells hidden in the substance of the frond. The flowers have a small number of free stamens, and a striated ovary, the stigmas of which are dilated and membranous, forming a sort of crest. [M. T. M.]

**LOPHOLENA.** A South African glabrous undershrub with entire leaves, forming a genus of *Compositae* closely allied to the discoid species of *Senecio*, but differing chiefly in the involucre, which has only five broad leafy scales, and in the long subulate appendages to the branches of the style.

**LOPHOLEPIS.** *Gontophlebium*.

**LOPHOPETALUM.** A genus of *Celastraceae*, consisting of three or four shrubs from tropical Asia, allied to *Euonymus*, but differing chiefly in the cells of the ovary always containing more than two ovules.

**LOPHOPHYTUM.** A genus of *Elaeagnaceae*, consisting of fleshy species with a thick rootstock attached to the roots of trees, and clothed in its upper part with overlapping scales. From this rises the flower-stalk, which at its upper end is divided into pimple-like branches provided with deciduous bracts; along these branches the flowers are arranged, the males having free stamens, and the females two styles. The inflorescence and flowers are stated by Dr. Hooker to resemble those of *Gunnera scabra*. One species is said to be eaten in Bolivia. [M. T. M.]

**LOPHOSORIA.** *Alseophila*.

**LOPHOSPERMUM.** A genus of *Scrophulariaceae*, of the tribe *Antirrhineae*, distinguished by a five-cleft herbaceous calyx; by a large tubular corolla, without any spur or pouch, and not closed at the throat as in *Antirrhinum*, but marked with two longitudinal hairy lines; by the globose capsule, each cell opening in an irregular pore below the apex; and by the seeds surrounded by a fringed wing. There are two species, *L. cruebecens* and *L. scandens*, both natives of Mexico, and both introduced into our gardens, where they are highly ornamental as herbaceous climbers with showy pink or red flowers. They support themselves by the petioles of their softly hairy triangular or cordate coarsely toothed leaves, and by their long often twisted axillary

**LOPHOSTEMON.** A Myrtaceous genus founded on an Australian shrub (now referred to *Fraxinea*), with alternate entire leaves, and white flowers in corymba. The calyx limb is divided into five reflexed deciduous segments provided with appendages at their base; petals five; stamens numerous, aggregated into five parcels, opposite the petals; fruit capsular, inferior, three-celled, many-seeded. [M. T. M.]

**LOPHOSTYLIS.** A name given by Hochstetter to the African species of *Securidaca*, in which the style is more dilated at the top than in the American ones.

**LOPSEED.** *Phryma*.

**LOQUAT.** *Eriobotrya japonica*.

**LOQUE.** (Fr.) *Solanum Dulcamara*.

**LORANTHACEÆ.** (*Viscoideæ*, *Mysodendrea*, *Loranthæ*.) A natural order of dicotyledonous plants belonging to Lindley's acaul alliance of epigynous Exogens. Parasitic shrubs, with articulated branches, opposite exstipulate fleshy leaves, and hermaphrodite or unisexual flowers. Calyx tube adherent to the ovary, with bracts; petals four to eight, or confounded with the calyx; stamens four to eight, opposite the petals; ovary one-celled, with a solitary pendulous ovule. Fruit superior, succulent. Natives chiefly of the equinoctial regions of Asia and America, but a few are European and African. The mistletoe is *Viscum album*. There are 30 genera and above 400 species. Examples: *Loranthus*, *Viscum*. [J. H. B.]

**LORANTHUS.** A genus of dicotyledonous plants belonging to the *Loranthaceæ*, consisting of dichotomous branching shrubs, usually parasitic, with opposite or alternate entire leaves, and flowers in spikes, corymba, or panicles, sometimes unisexual. The calyx tube is ovate or top-shaped; the petals four to eight or five to six, free or united; the stamens equal in number to the petals and opposite to them, with introrse anthers dehiscing lengthwise. The berry is ovate or top-shaped, with one seed. They are natives of tropical and subtropical regions, and comprise nearly 200 species. [J. H. B.]

**LORATE.** Strap-shaped: the same as *Ligulate*.

**LORDS-AND-LADIES.** *Arisaema maculatum*.

**LORD-WOOD.** *Liquidambar orientalis*.

**LORICA.** The skin of a seed.

**LOREPENTALUM.** A genus of the witch-hazel order, having the petals long narrow and three-nerved; the lobes of the anther deciduous. *L. chinensis* is a native of China, with ovate entire leaves, unequal at the base, and covered with fine down. The plant is placed by some in the [G. D.]

The filamentary branched lichens.

**LOTIER ARBORESCENT.** (Fr.) *Carmichaelia australis*. — **ODORANT** *Melilotus carulea*. — **ROUGE.** *Tetragonolobus purpureus*.

**LOTOS.** *Sisyrinchus Lotus*.

**LOT-TREE.** *Pyrus Aria*.

**LOTUS.** A genus of *Leguminosæ*, of the suborder *Papilionaceæ*, easily known by its leaves consisting of five leaflets, of which two are close to the stem, and assume the appearance of stipules. There are about twenty species known, all herbaceous, the flowers on axillary peduncles, either solitary or in little umbels, yellow, red, or of a deep purple almost black; the calyx five-toothed, the corolla remarkable for its very pointed keel, the stamens diadelphous, and the pod cylindrical or somewhat flattened, with several seeds. The species are most of them European or North African, but a few are spread over Asia and Australia.

*L. corniculatus*, a decumbent perennial, with umbellate yellow flowers and a cylindrical pod, is the most common British species, and is found in the greater part of Europe, in Northern Africa, Northern and Central Asia, and in Australia. The larger varieties form a very good ingredient in our meadows and pastures. *L. purpureus*, formerly cultivated in our gardens for its dark red flowers, *L. biflorus*, and some allied species, constitute a considerable portion of the meadows of Sicily and other parts of Southern Europe; they, with *L. siliginosus*, a more common European maritime species, are often separated as a distinct genus under the name of *Tetragonolobus*, on account of the ripe pod having four longitudinal ribs or wings. *L. Dorycnium*, and some allied species from Southern Europe, constitute the genus *Dorycnium* of some botanists. *L. hirsutus*, with a few others, also South European, have been detached under the name of *Bonjeania*; and *L. glaucus*, with some other Canary Island species, under that of *Pedrosia*; but all these genera are founded on characters too trifling for general adoption.

**LOTUS.** A mythic name for the flower of *Nelumbium speciosum*. — **EGYPTIAN.** *Nymphaea Lotus*. — **HUNGARIAN.** *Nymphaea thermale*. — **INDIAN.** *Nymphaea pubescens*.

**LOTUS-BERRY.** *Byrsonima coriacea*.

**LOTUS-TREE,** or **LOTE-TREE.** *Sisyrinchus Lotus*; also reputed to be *Celtis australis*. The true Lotus-tree of the ancients is, however, more probably referred to *Nicotiana glauca*. — **EUROPEAN.** *Disopyros Lotus*.

**LOUDONIA.** A genus of *Haloragacæ* from Australia, comprising three glabrous erect perennial herbs. *L. aurea* has the stem leafy at the base; the leaves alternate, leathery, linear, entire; the panicles terminal, corymbose; the flowers yellow, with the calyx tube four-winged, and its limb

four-parted; four petals, and eight stamens; and a fleshy clavate-tetragonous fruit. [J. T. S.]

LOUFF. *Luffa aegyptiaca*.

LOUREA. A genus of *Leguminosae Eedy.* *sarces*, nearly allied to *Desmodium*, but with a broadly campanulate calyx, enlarged after flowering, and a pod consisting of two or more joints folded upon each other, as in *Urtica*. It comprises three or four species, natives of tropical Asia, one extending to Australia, herbs or undershrubs. With the habit of some *Desmodium*s. The leaves have one or three leaflets; the flowers are small, in terminal racemes or panicles. *L. vesperilionis*, from the Indian Archipelago, is remarkable for the form of its leaflets, transversely oblong, and three or four times as broad as long, such as to have been compared to bat's wings.

LOUREIRA. A name applied to a shrub or small tree, native of Cochin China, in honour of a Portuguese missionary who published a Flora of Cochin China in the latter part of the last century. It is very imperfectly known, and its place in the natural arrangement is not defined. Meisner, who founded the genus, placed it in *Anacardiaceae*; but it was transferred by Lindley to *Amygdalaceae*, with which, so far as one may judge by description, it has more affinity. Benthani and Hooker do not refer it to any order, but speak of it as 'genus omnino ignotum.' According to Loureira (who calls it *Folysera cochinchinensis*), the whole plant is sweet and aromatic, and is employed medicinally by the natives. [J. Br.]

LOUSEBERRY-TREE. *Eunymus europaeus*.

LOUSE-BURR. *Xanthium Strumarium*.

LOUSEWORT. *Pedicularis*.

LOVAGE. *Levisticum officinale*; also *Achillea ligustica*, and a common name for *Ligusticum*.

LOVE. *Clematis Vitalba*.

LOVE-FLOWER. *Agapanthus*.

LOVE-IN-A-MIST. *Nigella damascena*.

—, WEST INDIAN. *Passiflora foetida*.

LOVE-IN-A-PUZZLE. *Nigella damascena*.

LOVE-IN-IDLENESS. *Viola tricolor*.

LOVE-LIES-BLEEDING. *Amaranthus caudatus*.

LOVEMAN. *Gallium Aparine*.

LOVE-TREE. *Cercis Siliquastrum*.

LOWEA. *berberidifolia* is a very singular and rare rosaceous plant, native of Northern Persia, and the Soongari desert, first described by Pallas, and by him referred to *Rosa*, in which genus it is now replaced. It is a little shrub, with yellow rose-like flowers, and simple obovate-cuneate serrated glaucous foliage. It agrees perfectly in the characters of its flowers with *Rosa*, but differs strikingly in its foliage. All true roses have pinnate leaves and stipules, whereas *Lowea* has either no leaves or no

stipules, according to the view taken of the nature of its leafy organs: for it is a matter of doubt whether these are true leaves without stipules, or stipules of suppressed leaves become confluent and putting on the appearance of leaves. In either case it is a remarkable plant. [A. S.]

LOWRY. *Daphne Laureola*.

LOXOGRAMMA. One of the genera of gymnogrammoid ferns, consisting of a few species with simple coriaceous fronds; uniformly reticulated venation, with free included veinlets in the areoles; and non-indusiate oblong or linear sori, the oblique receptacles occurring at intervals on each side the midrib. It comes near *Selliguea*, but has not the pinnate venation found in that genus. [T. M.]

LOXOSCAPHE. A group proposed to be separated from *Davallia*, in consequence of the oblique and subilateral position of the sori, which gives to them something of a darsoid character. The ultimate segments of the fronds are narrow, single-veined and soriferous obliquely at the apex, so that the indusium forms with the margin of the segment a short oblique boat-shaped cavity, instead of the usual straight terminal cyst of *Davallia*, with which in other respects these plants agree. The species are found in South America, South Africa, and the Pacific Islands. *L. gibberosa* is the type. [T. M.]

LOXSOMA. A genus of Australian ferns, closely related to *Trichomanes*, though having none of the pellucid character which belongs to that genus. It has, in fact, creeping rhizomes, with subcoriaceous decomposed fronds, dark above and paler beneath, the general aspect much more nearly resembling that of *Davallia*. The sori, however, are involucre in ex-torse marginal cysts, the veins run out into free filiform receptacles, and the sessile oblique-ringed spore-cases indicate that it should be placed with the *Trichomanes*. It has free veins. [T. M.]

LOZANIA. An imperfectly-known genus from New Grenada, formerly referred to *Vochysia*, but stated by Triana to be a species of *Lacistema*. [J. Br.]

LUBINIA. A genus of primworts, having the corolla almost salver-shaped, the border in five deep divisions, the two posterior of which are shorter than the others; the seed ovate, acute at the end, one-celled, and opening by two valves. *L. atropurpurea*, the only species, is an annual, a native of Mauritius, with fleshy, smooth, and obovate leaves. [G. D.]

LUCEE. Some myrtaceous tree whose leaves are used in Guiana for dyeing black.

LUCERNE. *Medicago sativa*.

LUCHE. A Chilean name for *Utea latissima*.

LUCID. Shining.

**LUCRABAN SEED.** An unrecognised oil-seed exported from Siam.

**LUOULIA.** The name given by the Nepalese to a tree of the *Cinchona* family, and latinised to form the generic title of a tree highly esteemed for the exceeding beauty and fragrance of its rose-coloured, somewhat fleshy flowers, which are borne in terminal corymbes. The linear segments of the limb of the calyx are deciduous; the corolla is salver-shaped, its limb five-cleft, with ovate-obtuse lobes; the anthers five, almost sessile on the throat of the corolla; stigmas two, fleshy, surmounting a thread-like style; capsule two-celled, two-valved, with many winged seeds. *L. gratissima* is the best known species. [M. T. M.]

**LUCUMA.** A genus of *Sapotaceæ*, containing between thirty and forty species, all natives of the American continent and the West Indian Islands, extending from Buenos Ayres to Mexico. Some are shrubs, others large trees, sixty to eighty feet high, or more, and, like most plants of the order, possessing a milky juice, and leathery entire leaves. Their flowers grow in clusters upon the sides of the branches, and are succeeded by large roundish fleshy eatable fruits. *L. mammosum*, one of these large trees, is a native of the West Indies and tropical America, where it is cultivated for the sake of its fruit, which is called Marmalade, or Natural Marmalade, on account of its containing a thick, agreeably flavoured pulp bearing some resemblance in appearance and taste to quince marmalade. This fruit is somewhat egg-shaped, three to five inches long, covered with a rusty-coloured skin, and contains usually a single hard seed. *L. Caimito*, whose fruit is called Caimito in Peru, is smaller than the foregoing, being only about three inches long, but its pulp is softer and superior in point of flavour. [A. S.]

**LÜDDEMANNIA.** A genus of orchids proposed to be separated from *Cynoches*, and distinguished by its sessile pollen-masses and minute caudicle, as well as by the form of the lip. It is allied to *Lacena*, from which the sessile depressed spherical pollen-masses and minute caudicle also distinguish it. *L. Pescatorei* is a Venezuelan species with the habit of *Acineta*, producing long pendent spikes of buff-yellow flowers, brown inside, with the petals and lip bright yellow. The lip is concave, wedge-shaped at the base, quadrate above, with the sides erect, and with a triangular lobe or tooth in front. [T. M.]

**LUDWIGIA.** A genus of *onagradæ*, distinguished from its allies by having the stamens four, equal to the number of petals; and the seed-vessel long and cone-shaped at the end. The species are Indian herbs, growing in marshes; the leaves alternate, narrow, entire, and shortly stalked; the flowers yellow, solitary, in the axils of the leaves. The name was given by Linnaeus in honour of Ludwig, Professor of Medicine at Leipzig. [G. D.]

**LUFFA.** A genus of *Cucurbitaceæ*, consisting of monoecious or dioecious herbs, with alternate petiolate rough leaves, simple tendrils, racemose male flowers, and solitary female flowers. The males have a bell-shaped five-toothed calyx, a five-parted corolla, and five stamens inserted in the calyx distinct or in bundles, with one-celled wavy anthers. The females have the calyx tube club-shaped and five-cleft, five petals, abortive stamens, and an inferior three-celled ovary with numerous ovules. The pericarp is ovate or oblong, fibrous within, containing many compressed seeds. The species are natives of tropical Asia and Africa. [J. H. B.]

**LUGAR.** An unrecognised tanning bark imported from Singapore.

**LŪHEA.** A genus of *Tiliaceæ*, consisting of South American or Mexican trees or shrubs, clothed more or less with stellate down, alternate leaves usually toothed, and showy white or pink flowers either in axillary cymes or terminal panicles. Each flower is enclosed in an involucre of several linear bracts, often longer than the calyx; the petals are thickened at the base, but without any pit or scale; the stamens very numerous, the outer ones barren; the capsule hard and woody, opening at the top in five valves, and containing several winged seeds in each cell. There are about sixteen species known, most of them very handsome when in flower. The wood of *L. divaricata*, which is white and light, but very close-grained, is used in Brazil for musket-stocks, wooden shoes, &c., and the bark of *L. grandiflora* for tanning leather.

**LUISIA.** A genus of inconspicuous epiphytal caulescent erect orchids of tropical Asia and America, with terete rigid rush-like leaves, and small dingy green or purplish or yellowish flowers of very little interest. [T. M.]

**LULUP.** A vegetable touchwood or tinder, exported in large quantities from Labuan.

**LUMBANG.** The nuts of *Aleurites triloba* and *moluccensis*, from which an oil is expressed. They are called Candle Nuts.

**LUMBRICAL.** Worm-shaped; a term applied to the worm-like lobes of the frond of certain seaweeds.

**LUNAIRE.** (Fr.) *Lunaria*. — **GRANDE.** *Lunaria biennis*.

**LUNANIA.** A genus of woody plants inhabiting the West Indies and South America, and belonging to the *Sampocaceæ*, though hitherto erroneously placed in *Flacourtiaceæ*. In habit and inflorescence it resembles *Osmelia*. The leaves are ovate, the flowers racemose and often emitting a disagreeable odour. The calyx is from four to five-cleft, the corolla wanting, the number of stamens is from six to ten, and there are scales or staminodia (abortive stamens) interspersed among them. The fruit is an ovate capsule. According to

Bentham's recent revision, there are five species of this genus. [B. S.]

**LUNARIA.** A genus of *Cruciferae* natives of Central and Southern Europe, and consisting of tall biennials or perennials with erect stems, large alternate or opposite cordate-acuminate leaves, and terminal racemes of large purple flowers having the two outer calyx segments bulging at the base. The pouch is very large, stalked, oval or oblong, flattened in the direction of the back, the partition silvery. *L. biennis* is the Honesty of gardens. [J. T. S.]

**LUNARIE.** *Botrychium Lunaria*.

**LUNASIA.** *Rabelaisia*.

**LUNATE** (dim. **LUNULATE**). Crescent-shaped.

**LUNETIÈRE** (Fr.) *Biscutella*.

**LUNG-FLOWER.** *Gentiana Pneumonanthe*.

**LUNGS-OF-THE-OAK.** *Sticta pulmonacea*.

**LUNGWORT.** A name given to *Sticta pulmonacea*, a lichen which in moist sub-alpine countries grows abundantly on the trunks of trees. It is occasionally used, like Iceland moss, in diseases of the lungs, and for other medical purposes. It is also said to be employed in Siberia as a substitute for hops. The name is also given to *Pulmonaria officinalis* and *Hieracium pulmonarium*. —, **BULLOCK'S.** *Verbascum Thapsus*. —, **SMOOTH.** *Mertensia*. —, **TREE.** *Sticta pulmonacea*.

**LUNULARIA.** A remarkable genus of *Marchantiaceae*, belonging to the natural order *Lunulariales*, with crescent-shaped involucre to the gemmae, and a pedunculate capitate fruit, which consists of four capsules, each of them surrounded by a proper involucre, and opening, like that of a *Juncus*, with four valves. *L. vulgaris* has been found both in England and Ireland, but is more common southward. It occurs also in Chili. [M. J. B.]

**LUPINASTER.** A section of *Trifolium*, characterised by having large red white or yellow flowers in heads, with coriaceous persistent petals, and subulate erect calyx segments. The leaves are composed of from three to seven coriaceous leaflets, with numerous veins.

**LUPINE.** *Lupinus*. —, **BASTARD.** *Trifolium Lupinaster*. —, **SMALL.** *Psoralea Lupinella*.

**LUPINUS.** A genus of *Lupinaceae* of the suborder *Psoraleaceae*, like *Gentiana*, characterised chiefly by the two-lipped calyx, monadelphous stamens, and the keel-petal ending in a point or beak as in *Orotalaria*, but differing from that genus in the flattened pod. The species are very numerous in America, especially towards the western side, extending from Oregon to South Chili, but more rare within the tropics excepting in the mountainous districts. In the Old World the genus is confined to a few annual species in the

countries bordering on the Mediterranean. The species are all herbs or undershrubs. The leaves consist of five or more digitate leaflets, or in some species are simple and entire: the flowers are blue, white, purple, or yellow, in terminal racemes or spikes, and often very handsome.

The genus is one of the most puzzling to botanists, who would distinguish its numerous species by positive characters, and cultivation appears in many instances to obliterate those distinctions which may be observed in the wild state. The following are the most remarkable among those found in gardens:—*L. albus*, an annual attaining two three or even four feet in height, with five or seven leaflets to its leaves, and rather large white or pale-coloured flowers. It is probably of Egyptian or East Mediterranean origin, and has been cultivated since the days of the ancient Egyptians. It is now very extensively sown in Italy, Sicily, and other Mediterranean countries for forage, for ploughing in to enrich the land, and for its round flat seeds, white outside but yellow internally, which when hoiled, so as to remove the bitter somewhat deleterious principle, form a great article of food in some districts. It used also to be much grown in flower gardens, together with *L. luteus* with sweet-scented yellow flowers, and *L. varius* with differently coloured flowers, but usually of a rich blue, both of them annuals of Mediterranean origin. These have now been mostly superseded by some of the American and especially Californian kinds. Above a hundred of these are known, and most of them are ornamental. More than thirty have been at different times introduced. *L. arboreus*, from California and Oregon, will, when well trained, produce a branching stem several feet in height that will live through four or five years, forming a trunk of light soft wood of the thickness of a man's arm. *L. polyphyllus*, and a few allied species from the same country, are tall erect herbaceous perennials with very handsome richly coloured spikes of flowers, which have become permanent inmates of our gardens. *L. versicolor* (or *L. Orszakshanskii*), a tall annual from Peru, *L. affinis*, *L. nanus*, &c., Californian annuals, are also now common with us, and scarcely one of the genus can be considered as worthless in a flower garden.

**LUPIS.** The fine inner fibre of *Musa textilis*.

**LUPULINE.** Waxy globules, resembling pollen, found on the bracts of the female flowers of the hop.

**LUPULINE.** (Fr.) *Medicago lupulina*.

**LUPULINOUS.** Resembling a head of hops.

**LURID.** Dirty brown, a little clouded.

**LUS-A-CHRAOIS.** (Gael.) The plant of glutinous, *Cornus suecica*.

**LUSTRE D'EAU.** (Fr.) *Chara*.

**LUSTWORT.** *Drosera*.

**LUTEOFUSCIOUS.** Between yellow and fuscous.

**LUTEOLUS.** Pale yellow. The same as *flavescens*.

**LUTESCENS.** Yellowish.

**LUTEUS.** Such yellow as gamboge.

**LUVUNGA.** A genus of Indian auran-tiaceous shrubs of climbing habit, often spiny, having ternate leaves, and flowers in axillary clusters or tufts. The calyx is cup-like; the petals four or five, oblong; the stamens eight to ten, free or combined into a tube, with linear anthers; the ovary two to four-celled, with two ovules in each cell. *L. scandens* has clusters of flowers whose appearance and fragrance resemble those of the orange. [M. T. M.]

**LUXEMBURGIA.** A genus of *Ochnaceæ*, consisting of showy branching smooth shining trees or shrubs, with alternate leathery serrulate stipulate leaves, and terminal racemes of yellow flowers, having five unequal deciduous sepals; five imbricate-convolute petals; and hypogynous stamens, eight or indefinite, with linear anthers biporate at the apex. The capsule is leathery, one-celled, with numerous seeds. They are natives of Brazil. [J. H. B.]

**LUXURIA, LUXURIES.** Rankness; an unnaturally exuberant growth.

**LUZERNE.** (Fr.) *Medicago sativa*. — **DE SUEDE, FAUCILLE, JAUNE, or SAUVAGE.** *Medicago falcata*.

**LUZULA.** A genus of perennial herbaceous plants allied to the rushes, from which they may be distinguished by their seed-vessels each containing three seeds only, and by their flat leaves which are generally furnished with sparse long hairs. Several species are British. One of them, *L. campestris*, is popularly called a grass, but may at once be detected by its pilose leaves. *L. sylvatica* is a large species, bearing on leafy stalks, two feet high, its spreading panicles of rush-like flowers collected into small tufts. *L. spicata* is a sub-alpine species a few inches high, having its flowers in a nodding spike, which is somewhat compound at the base. There are many foreign species. [C. A. J.]

**LUZURIAGA.** A genus of *Liaceæ* from Chili and Peru, consisting of branched undershrubs, creeping on the stems of trees, and adhering to them by rootlets, having alternate leaves, and solitary axillary peduncles bearing umbels of yellowish-white flowers with purple dots; the perianth six-leaved, spreading and deciduous; the stamens six; and the berry three-celled, with two seeds in each cell. [J. T. S.]

**LYALLIA.** A genus of *Portulacacææ*, consisting of a small undershrub from Kerguelen Land, with somewhat the habit of *Lycopodium Selago*, the stem, however, being much branched, with imbricated adpressed leaves, small solitary terminal flowers with a four-parted calyx, and a one-celled subglo-

bular utricular fruit with three seeds, two of which are abortive. [J. T. S.]

**LYCASTE.** The orchids now associated in this genus were formerly referred to *Maxillaria*, from which they are well distinguished by the two pairs of pollen-masses being seated on a long caudicle attached to a small roundish gland; while from the other allied genera they are distinguished by the middle of the lip being furnished with a transverse fleshy entire or notched appendage. They number a score or more of species, exclusively tropical American; but some, being found in the cool mountain regions, are suited for growing in green-houses or even in dwelling-rooms, and of these *L. Skinneri*, decidedly the finest of the genus, is the best example. The *Ly-castes* have short unjointed pseudobulbs, and plicate leaves. Their flowers, borne singly upon the top of stalks rising from the base of the pseudobulbs, are showy and often of large size, with their sepals and petals frequently dissimilar, and with two of the former combined at the base and protruded in front like a chin. [A. S.]

**LYCHNIDE DES JARDINS.** (Fr.) *Lychnis coronaria*. — **LACINIÉE.** *Lychnis Flos-cuculi*. — **ROSE DU CIEL.** *Viscaria Cœli-rosa*.

**LYCHNIS.** The Campion, a genus of *Caryophyllacææ*, distinguished by having five styles. As this character is artificial, various attempts have been made to divide the genus into others, but in many instances the proposed divisions are founded on characters as artificial as those which are assigned to the group as a whole. The following may be taken as genera or sub-genera:—1. Those in which the capsule opens by as many teeth as there are styles:—*Eulychnis*, calyx membranous in front; capsule septicidal; seeds stalked, rough with small tubercles. The Scarlet Lychnis (*L. chalcedonica*) and the Ragged Robin (*L. Flos-cuculi*) with pink flowers are examples of this. *Petrocoptis* differs from the last only in having the seeds sessile and quite smooth, as in *L. pyrenaica*, a white-flowered species. *Viscaria*, distinguished from the two preceding by the capsule splitting loculicidally; to this belong two British species, *L. Viscaria* and *L. alpina*, both having rose-coloured flowers. *Coronaria*, in which the calyx is thickened in fruit; the Rose Campion (*L. coronaria*) is a good example. *Agrostemma*, same as in the last, but without the scale-like appendages which occur at the base of the limb of the petals, forming the so-called crown; the Corn Cockle (*L. Githago*), and a closely allied species *L. gracilis*, are the only species which answer to this character. 2. Those in which the capsule opens by twice as many teeth as there are styles; nearly allied to *Silene*:—*Melandrium*, calyx teeth regular; calyx ovoid, with the veins not prominent in fruit, as in *L. vespertina* and *L. dioica*, the common wild Campions. *Wahlgbergella*, like the last, but the calyx teeth are combined in pairs, and the petals

are small or absent; they are all arctic plants. *Eudianthe*, calyx clavate, with the veins prominent in fruit, and often roughened, as in *Viscaria Cohn-rosa*. [J. T. S.]

#### LYCHNIS, ROCK. *Viscaria*.

**LYCOPLESIMUM.** A few South American shrubs constituting a genus of *Solanaceæ*. They have spiny stems, rather thick leaves somewhat closely packed together in tufts, and solitary or axillary flowers, with a bell-shaped five-toothed calyx, and a tubular reddish-coloured corolla, whose limb is divided into five acute lobes. The fruit is succulent, enclosed within the persistent calyx, and of a red or orange colour. The generic name is expressive of its close affinity to the genus *Lycium*. [M. T. M.]

**LYCIUM.** A name applied to some thorny shrub by Dioscorides, and now adopted for one of the genera of *Solanaceæ*. The species are shrubs, natives of the Mediterranean region, and of some parts of tropical America. Their inflorescence is various. The calyx is cup-shaped, five-toothed, sometimes irregular; the corolla funnel-shaped or tubular, with a five-cleft limb; stamens five, the anthers opening lengthwise; ovary two-celled; fruit succulent in the cup-like calyx.

The species are numerous. Some are grown in greenhouses, whilst others are hardy. Among the latter is *L. barbarum*, a plant which, from its rapid growth, green foliage, and small lilac flowers, which are succeeded by scarlet or orange fruits, is often met with in gardens. It is well adapted to cover trellises, walls, &c., and is known as the Duke of Argyll's Tree, its leaves being recommended for use in place of tea—a piece of advice not generally acted upon, it would seem. The plant may sometimes be found in a semi-wild state in hedges, having escaped from cultivation. *L. europæum* is made use of as a hedge plant in Tuscany and Spain, and the young shoots are employed as a vegetable. *L. afrum*, a spiny species with violet flowers, forms a handsome plant on a sheltered wall. [M. T. M.]

**LYCOGALA.** A genus of myxogastrous Fungi, familiar to many from one of its species giving out in its young state, when divided, a rich blood-like pulp. When dry, *L. epidendrum* forms globose somewhat furfuraceous bodies about the size of a nut, filled with dull pinkish-grey cinereous dirty white or yellowish spores, and a few threads which are attached to the walls. It occurs on sticks in woods, and has a wide geographical range. The variability in the colour of the spores is singular, though a parallel example occurs in the genus *Althium*. [M. J. B.]

#### LYCOPERDE DES BOUVIERS. (Fr.) *Lycoperdon Bovista*.

**LYCOPERDON.** One of the principal genera of the natural order *Trichogastres*, among the gasteromycetous Fungi. The peridium is double, but the outer coat, which breaks up into warts, spines, scales,

&c., is intimately connected with the inner coat, and the spores are mostly sessile, though occasionally stipitate as in *Bovista*, from which it is distinguished by its less persistent inner peridium, and more adnate outer coat. The species are produced abundantly in almost every country, but are so variable that it is often very difficult to distinguish them. *L. Bovista*, when quite young, in which state even, it attains a large size, is one of the best of fungi if cut in slices and fried, but we cannot say much in favour of other large species. The dry mass of threads and spores is used as a styptic, and its fumes answer the purpose of chloroform. The spores are generally more or less olivaceous, but occasionally they assume a purple tint. [M. J. B.]

**LYCOPERDON NUTS.** The name under which the herbalists sell our common species of *Blaphomyces*. [M. J. B.]

**LYCOPERSICUM.** A genus of *Solanaceæ* established by Tournefort, but afterwards combined with *Solanum* by Linnaeus, although now generally recognised by modern botanists as distinct. Ten species, all natives of South America, chiefly of the Peruvian side, are described. They are either annual or perennial herbaceous plants, generally with weak stems trailing upon the ground or supporting themselves on other plants; they have irregularly pinnate leaves, and stalks bearing many flowers growing from the sides of the stems. The flowers are easily distinguishable from those of the allied *Solanum*, by their stamens having the anthers connected together by a thin membrane which is prolonged upwards, and by their cells opening by means of a long slit down the inside, instead of by two pores or holes at the top. The fruits are fleshy, usually red or yellow, and very glossy, and are divided into two, three, or many cells, containing numerous seeds imbedded in pulp.

*L. esculentum* is the Tomato or Love Apple. It is an annual plant, native of the warmer parts of America, but long ago introduced into most other warm or temperate countries, where it is cultivated for the sake of its wholesome fruit. It was brought to Europe in the early part of the sixteenth century, soon after the discovery of America, and is now extensively grown in many parts; but in this country, owing to the shortness of our summers, its fruit does not always come to perfection. Several varieties are cultivated, differing only in the size and shape and red or yellow colour of their fruits. Two, however, are considered by some botanists as distinct species, and are named *L. cerasiforme* and *L. pyriforme*—the sole distinction between them being that the first-mentioned has a round two-celled fruit rather larger than a cherry, and the other a pear-shaped two-celled fruit about an inch and a half long; while the more common *L. esculentum* has a large irregularly shaped furrowed fruit, divided into several cells, the irregularity and multiplicity of cells, however, being frequently owing to two or more flowers

having joined together so as to produce only one fruit.

Tomatos are much more commonly used for food in the south of Europe and other parts of the continent than they are in this country. Near Rome and Naples whole fields are covered with it, the fruit being one of the most common articles used in Italian cookery. Now that their agreeable qualities are better known, they are beginning to be more generally appreciated with us, and, in addition to those grown in this country, considerable quantities are imported from the continent. Although they belong to a family usually looked upon with suspicion, on account of the narcotic poisonous properties of so many plants belonging to it, they, in common with the fruits of many *Solanums*, are perfectly wholesome, and may be freely eaten. In a green state, Tomatos form an excellent pickle, and when ripe, various delicious sauces and ketchups are made of them; besides which they are largely eaten either raw, or when cooked in various ways. Used as an article of diet, they are considered beneficial in affections of the liver, indigestion, diarrhoea, and other complaints. The word Tomato is derived from the Spanish-American name *Tamate*; and the other common English name, Love Apple, has arisen from their supposed power of exciting tender feelings. [A.S.]

**LYCOPODE.** Vegetable blinestone, the highly inflammable powder contained in the spore-cases of *Lycopodium clavatum* and *L. Selago*.

**LYCOPODIACEÆ.** A natural order of Acrogens, consisting of two very distinct groups, one of which contains numerous species with the habit of the larger mosses or conifers, and the other of aquatics which have a more or less herbaceous aspect. *Phylloglossum*, consisting of a single species, is, however, nearly intermediate. They are distinguished from ferns by the absence of a ring to the capsules, which are either bi-tri-valved or altogether anomalous (see *ISOETES*); by their different mode of germination; and, as far as is known, by the very different character of their antheridia. In *Selaginella* there are two distinct kinds of capsules, the one producing large four-sided (globose-tetrahedral) spores, and the other smaller antheridia. The spores germinate by cell-division on one side, a quantity of archegonia being produced in the cellular stratum formed during the process of germination; the antheridia, which at first have quite the appearance of spores or pollen grains, after several weeks produce spiral spermatozooids from their cavity, by means of which the embryo cell in each archegonium is fertilized. This in due time becomes further organized, acquires a distinct root and axis, and finally produces a dicotyledonous embryo strongly resembling that of phanerogams. In the other genera whose fruit has been examined, the process of reproduction is essentially the

In *Lycopodium* there is no distinct second fruit, and the details of germination are at present unknown. It is conjectured that the cellular stratum produced during germination, or in other words the prothallus, produces antheridia together with the archegonia as in ferns. This is, however, very uncertain. The stem, when well developed, consists of a mass of thick-walled often dotted cells, enclosing one or many bundles of scalariform tissue, which send off branches to every leaf and bud. This is occasionally accompanied by distinctly reticulated cells. There is, however, no crossing of bundles as in Endogens, and there are no medullary rays. In many respects the structure is that of ferns.

a. *Selaginella spinulosa*.  
b. *Lycopodium clavatum*.

*Lycopodiaceæ* occur in all parts of the world, but far the finest species and the most abundant occur in the tropics or in countries where there are no very striking distinctions of temperature. The finest modern lycopods, however, cannot bear comparison with the *Sigillaria* and *Lepidodendron* of ancient strata, which vie with tree-ferns in their stem and with conifers in their fruit. In essentials their stems agree in structure with modern lycopods, that of *Lepidodendron* consisting of a central mass made up principally of large scalariform vessels which send off branches to the leaves through the surrounding thick-walled cells. *Sigillaria*, however, takes a step towards phanerogams, having, instead of a nearly uniform central mass, wedges of vessels interrupted by rays from the surrounding cellular tissue. [M. J. B.]

**LYCOPODIUM.** One of the two great genera of lycopods, known more especially by the name of Clubmosses. They are distinguished from *Selaginella* by the coniferous habit, and single form of capsules. The species vary greatly in size, and while some are quite prostrate, others are erect,

and some again attain such dimensions that they might at first sight be really taken for conifers. The leaves vary from mere threads to broad imbricated scales. The heads of fruit are mostly distinct and cylindrical, and sometimes branched. The same species may assume such various forms under different circumstances as to be recognised with difficulty. Dr. Hooker has given a remarkable instance of this in *L. densum*, a common New Zealand species. Species of *Lycopodium* occur in cold, temperate, and tropical countries, and six occur in our own islands. *L. cernuum*, one of the most widely diffused species, ascends as far north as the Azores, where it is found in the neighbourhood of warm springs; and it is found again as far south as St. Paul's.

Some of the species are cathartic when fresh, but they seem to lose their virtue when dry. One is commonly used as a medicine in Madeira, and *L. catharticum* has, as the name implies, a medical reputation in South America. A blue dye is prepared from some species, and the spores of our common *Cladonia* are used on the stage to produce artificial lightning, from their highly inflammable nature. They are also employed by apothecaries to keep pills from sticking together. They have such a strong repulsive power, that if the hand is powdered with them, it can be dipped in water without becoming wet. *L. alpinum* is the badge of the McRae's, *L. clavatum* that of the Sinclairs. [M. J. B.]

**LYCOPSIS.** A genus of *Borraginaceæ*, now united to *Anchusa*, from which it differs only in the tube of the corolla being slightly curved. *L. arenaria*, a hispid annual with small blue flowers, is a common weed in cultivated ground. [J. T. S.]

**LYCOPUS.** A genus of labiates, having the corolla scarcely longer than the calyx, bell-shaped and four-cleft; the two lower stamens alone perfect, the upper wanting or imperfect; and the ripe fruit with thick margins. The species are herbs usually inhabiting marshes, in Europe, Asia, North America, and Australia. [G. D.]

**LYCORIS.** The plants separated under this name by Herbert are now regarded as forming a section of *Amaryllis*, technically distinguished by the undulated divisions of the spreading perianth being curved upwards, and by the style having likewise a curve upwards and bearing a simple fringed stigma. They are natives of Eastern Asia and Africa. [A. S.]

**LYCOTROPAL.** An orthotropal ovule curved downwards like a horse-shoe.

**LYGEUM.** A genus of grasses belonging to the tribe *Phalaridæ*. The inflorescence is contained in large sheath-like bracts, which have two or three florets, without glumes, with the base of the pales hardening into a two-celled seed-vessel. *L. Spartum*, the only species, [is one source of the valuable Esparto grass, which is so largely imported and extensively employed for paper-making]. It is

a rather handsome grass, which has extensive underground stems or rhizomes, and hard wiry leaves. [D. M.]

#### LYGODICTYON. *Hydroglossum*.

**LYGODIUM.** A genus of scandent ferns of the group *Schizæneæ*. The species are rather numerous, and widely dispersed over the warmer parts of the world, extending to New Holland, Japan, and North America. The fronds are branched, with a scandent rachis, and they usually bear conjugate branches, which are variously divided in a digitate or palmate manner, or else they are 1 unatifid, or sometimes pinnate. The fructifications form compressed distichous spikelets, somewhat resembling in aspect those of *Selaginella*, but exerted on marginal teeth of the fronds. These spikes consist of bract-like indusia, each covering a single spore-case which is resupinate, and furnished with a many-rayed apical ring. The veins are free, which distinguishes this genus from *Hydroglossum*. They are plentiful in our hothouse collections of ferns. [T. M.]

**LYGODYSODEA.** This harshly sounding name seems to be derived from the Greek words *lynos*, a slender branch or twig, and *dysodos*, pathless, in allusion probably to the obstruction caused by the climbing habit of the plants to which it is applied by botanists. The genus consists of Mexican and Peruvian shrubs of the *Cinchonaceæ*, characterised by an ovate calyx tube, having a five-toothed limb; a funnel-shaped corolla, with five revolute limb segments; five sessile anthers; and an inferior two-celled ovary, surmounted by a disk. The fruit consists of two carpels, crowned by the teeth of the calyx, and separating when ripe. [M. T. M.]

**LYMPH.** Sap; the crude unelaborated fluid of vegetation. *Lymphæducts* are sap-vessels.

#### LYONIA. *Eubotrys*.

**LYONETIA.** A genus of *Compositæ*, closely allied to *Anthemis*, from which it is scarcely separable. It includes four annual species, natives of the Mediterranean region; and a fifth perennial species is doubtfully placed in the same genus by De Candolle. They have pinnatifid alternate leaves, and naked stems surmounted by solitary heads of yellow flowers. They have been referred by various authors to *Cotula* and *Anacyclus*. [J. Br.]

**LYONSIA.** A genus of the dogbane order, distinguished by having the stigma of a conical form, and the fruit a cylindrical capsule with two cells. *L. straminea*, a native of Australia, the only species, is a twining shrub with opposite leaves, named in honour of Mr. Lyons, who published a Flora of Cambridge. [G. D.]

**LYPERIA.** A genus of *Scrophulariaceæ* of the tribe *Gratiolææ*, and nearly allied to *Manisca*, but distinguished chiefly by the slender tube of the corolla, which is more or less curved or gibbous at the back near the top. There are about thirty species,

natives of the Cape Colony in Southern Africa. They are all herbs or low branching undershrubs, the leaves opposite or the upper ones alternate, usually small, entire toothed or divided, and often clustered in the axils. The flowers are axillary or in terminal spikes or racemes, usually more or less viscidous, and always turn black in drying; when fresh, they are usually yellow or purple, or in some species of that peculiar greenish-yellow, with a brown tinge outside, which is usually accompanied by a tendency to exhale a sweet scent at the close of the day. [The flowers of *L. crocea* have been imported under the name of African saffron.]

**LYRATE, LYRESHAPED.** Pinnatifid, with the upper lobes much larger than the lower.

**LYROCARPA.** A genus of *Cruciferae* from California, distinguished by its fiddle-shaped two-lobed pouch. [J. T. S.]

**LYSILOMA.** A genus of *Leguminosae* of the tribe *Mimoseae*, formerly combined with *Acania*, from which, however, it is distinguished by the stamens, which seldom exceed thirty in number, being united at the base into a tube unconnected with the corolla, and also by the thin flat pods having, as in *Mimosa*, *Entada*, &c., a thickened margin, which remains entire, while the thin inner portion breaks away in the centre, so as to allow of the escape of the seeds. The eight or ten species are inhabitants of tropical America, and are either shrubs or large trees, destitute of prickles, and resembling in general appearance the acacias of the same regions, having twice pinnated leaves, and round or cylindrical heads of small flowers. The genus is of considerable importance in an economic point of view, on account of one of its species yielding the valuable hard timber known as Sabelo, Savaco, or Savico wood, the origin of which was long unknown, but which has now been ascertained to be the produce of a species of this genus to which the name *Sabicea* has been given. *Sabicea* timber is imported in considerable quantities from Cuba, where only the tree is known to exist. It is a dark-coloured wood, very heavy, excessively hard, and extremely durable, the two latter qualities rendering it of great value to the ship-builder, by whom it is much esteemed. On account of its hardness it was selected for the stairs of the building for the Great Exhibition in 1851, and, notwithstanding the immense number of people who passed up and down, the stairs were found, at the close of the Exhibition, to be scarcely at all the worse for wear. [A. S.]

**LYSIMACHIA.** A genus of herbaceous mostly perennial plants belonging to the *Primulaceae*, and allied to *Anagallis*, from which they are distinguished by having glabrous, not hairy, filaments, and a capsule which opens at the summit with five or ten valves. *L. nemorosum*, the commonest British species, approaches in size and habit the scarlet pimpernel, but has

bright yellow flowers; from this resemblance it is often called Wood Pimpernel. *L. Nummularia*, Moneywort or Herb Twopence, is a trailing plant common on the margins of rivers, the banks of which it often fringes with pendent stems, thickly set with roundish glossy leaves, and large bright yellow flowers. It is often cultivated in gardens as a decoration to rock-work, especially where water is introduced, or is grown as a window plant and allowed to droop over the sides of the pot. There are many foreign species, most of which bear yellow flowers and affect moist situations. French, *Lysimachie*; German, *Gelbe weidenich*. [C. A. J.]

**LYSINEMA.** A small genus of *Epacridaceae*, natives of New South Wales and South-west Australia, and having a coloured calyx surrounded with bracts of the same texture as the calyx; a salver-shaped corolla, the tube of which is often divisible into five parts, the segments of the limb smooth and inclined to the right; and the stamens attached below the ovary, and having petalate anthers. They are handsome shrubs, with white or rose-coloured flowers in sessile axillary spikes; the leaves smooth and sharp-pointed. [R. H.]

**LYSIONOTUS ternstrofia** is an erect glabrous herb inhabiting Nepal, and the sole representative of a genus of *Cyrtandraceae*. The leaves are ovate-lanceolate and arranged in whorls; the flowers are of a fine rose-colour, and arranged in terminal umbels. The calyx is five-cleft, the corolla bell-shaped, and the stamens five, two of which are fertile. The fruit is capsular, bilvalved, and encloses an indefinite number of seeds. [B. S.]

**LYSIOSTYLES.** A genus of *Convolvulaceae*, containing a single species, a native of British Guiana. It is a climbing shrub, with alternate petiolate oblong leaves, and flowers in axillary panicles. The calyx is five-cleft, with imbricated lobes; the corolla tube short, and the limb rotate and five-parted; there are five stamens; and the ovary is one-celled, with four erect ovules, surmounted by two styles, completely separate, and each with a capitate stigma. The genus is nearly related on the one hand to *Maripa*, on the other to *Erycibe*, yet abundantly distinct from either. It belongs to the group which Decandolle has raised to the rank of a natural order under the title of *Erycibea*. [W. G.]

**LYSIPOMA.** The name of a genus of small herbaceous plants of the *Lobeliaceae*, natives of the Andes. The genus is known by the calyx, which has a five-nerved tube and a five-parted somewhat two-lipped limb; by the funnel-shaped corolla, with an entire distended tube and two-lipped limb, the upper lip of two, the lower of three divisions; by the five stamens united into a tube, the two lowermost anthers hairy, and by the inferior one-celled ovary. The capsule opens by a little lid at the top. [M. T. M.]

**LYSURUS.** A genus of phalloid *Fungi*, in which the receptacle of the fruit is split into a few free laciniae. In other respects it resembles *Phallus*. The ashes of *L. Mokusis* are applied in China as a remedy to ulcerous sores. It is also sometimes eaten, but often proves poisonous. [M. J. B.]

**LYTHRACEÆ.** (*Salicaria*, *Calycanthemum*, *Lythraea*, *Loosestrifæ*.) A natural order of dicotyledonous plants, belonging to Lindley's saxifragal alliance of perigynous Exogens. Herbs, rarely shrubs, often with square branches, and usually opposite entire exstipulate leaves. Among the allied perigynous exalbuminous orders, it is distinguished by its tubular calyx, enclosing a two to six-celled ovary which is free from it; its united styles; its membranous capsular fruit; and its stamens inserted in the calycine tube below the petals. The plants are chiefly tropical, but some are found in Europe and North America. They have astringent qualities. Examples: *Lythrum*, *Cuphea*, *Lagerströmia*. *Lawsonia alba* yields the henna of the Arabs. There are forty genera, and upwards of three hundred species. [J. H. B.]

**LYTHRUM.** A genus of herbaceous plants, mostly perennials, giving name to the *Lythraceæ*. In these plants the tubular calyx has eight to twelve teeth, the alternate ones awl-shaped; the petals are four to six, and the capsule is two-celled. The genus is well represented in Britain by *L. Salicaria*, the Purple Loosestrife, a tall and very handsome plant, three to four feet high, with opposite lanceolate leaves, and long terminal leafy spikes of densely whorled purple flowers, common in most parts of Britain, often occupying a large space in marshy meadows, or lining a watercourse for a considerable extent, and thus to be classed among the few plants which, by breadth of colour, tend to characterise a landscape. There are many foreign species, of which *L. virgatum*, a native of Austria, sometimes cultivated, resembles *L. Salicaria* in habit, but is more branched above, and bears its flowers, which are large, in whorls of three or four. French, *Salicatre*; German, *Braune weidenrich*. [C. A. J.]

**MABA.** A genus of *Ebenaceæ*, differing from *Diospyros* in the calyx and corolla having each only three lobes, instead of four or more. It consists of nearly twenty species, dispersed over tropical Africa and Asia, the Pacific Islands, and North Australia, all shrubs or trees with alternate entire leaves, and small flowers, almost sessile, in their axils. The Ebony wood of Cochín China is believed to be the produce of a tree of this genus.

**MABEA.** A genus of *Euphorbiaceæ* of the tribe *Crotonææ*, consisting of tropical American shrubs, sometimes climbing, with alternate usually oblong entire or toothed leaves, and flowers in terminal racemes or panicles, the majority usually males, with a few females at the base. The perianth is valvate, without petals;

the males have numerous stamens, and the females a long three-cleft style with one ovule in each cell of the ovary. There are nine or ten species known, all of which yield a copious acrid milky juice. The bark of one of them is, according to Martius, considered in the diamond district of Brazil as a febrifuge, and the straight hollow young shoots of several species are used for tobacco-pipes in Guiana and North Brazil under the name of Tacuári.

**MACAHUBA.** A Brazilian name for *Acrocomia sclerocarpa*.

**MACARTHURIA.** A genus of South-west Australian herbs or undershrubs with erect rush-like stems, few small alternate leaves either linear or reduced to minute scales, and small flowers in lateral or terminal compact cymes. [It is allied to *Mollege*, from which it principally differs in the definite (eight) stamens united into a cup at the base: and the ovules, which are one, two, or three in each cell.] There are only three species known, and none are deserving of cultivation.

**MACARY-BITTER.** A West Indian name for *Picramnia Antilesmia*.

**MACAW-BUSH.** *Solanum mammosum*.

**MACAW-FAT.** A West Indian name for the Oil Palm, *Elæis guineensis*.

**MACAW-TREE.** *Acrocomia fusiformis* and *sclerocarpa*. —, **GREAT.** *Acrocomia lasiocarpa*.

**MACE.** The aril of the nutmeg, *Myristica moschata*; also an Indian name for the gall-nuts formed on *Tunmaria indica*. —, **RED.** The aril of *Pyrrhocalia tinpens*. —, **WHITE.** The aril of *Myristica Otoba*.

**MACERON.** (Fr.) *Smyrniolum*.

**MACFADYENA.** A genus of *Dignoniacæ*, named after Dr. Macfadyen, author of a Flora of Jamaica. The genus has a spathaceous calyx, funnel-shaped corolla, four fertile stamens of unequal length with glabrous divergent anthers, an elongated flat and smooth capsule, divided into two cells by a partition running parallel with

rous winged seeds arranged in single rows. There are about a dozen species, all inhabitants of the West Indies and the tropical parts of South America. They are climbing shrubs, with trifoliate and conjugate leaves, in the latter instance furnished with tendrils, and large bright yellow or more or less purplish flowers, appearing in the axils of the leaves, or in corymbs at the end of the branches. *M. uncatia* has for many years been an inmate of our hot-houses. Many of the species, from being imperfectly known, had until lately been classed with *Spathodea*. [B. S.]

**MACHERANTHERA.** A generic name proposed by Nees for the *Aster tanacetifolius*, described from specimens grown in the Botanic Garden of Mexico, and differing in some slight points from the majority of the species of the great genus *Aster*.

**MACHERINA.** A genus of cyperaceous plants, belonging to the tribe *Rhynchosporer*. The inflorescence is in panicles; scales of the flowers two-rowed, keeled; stamens three; styles three, cleft, thickened conically at the base; seeds or nuts pear-shaped. There are two species, one of which belongs to the West Indies, the other to New Holland. [D. M.]

**MACHERIUM.** An extensive genus of leguminous plants belonging to Central and South America, some forming large timber trees, others shrubs of moderate height, while others again are tall creepers, often armed with prickles. Their leaves are pinnate, and their flowers small, and purple violet or white. Their most obvious generic character resides in the fruit, which is compressed, but more or less thickened at the base where the solitary seed is situated, while the upper part is drawn out into a thin tapering wing terminated by the remains of the style.

Some of these trees are supposed to yield a portion of the Rose-wood of commerce. Notwithstanding the length of time Rose-wood has been known to our cabinet-makers, and the large quantities of it annually imported, its botanical history is very obscure, and it has been at various times referred to trees of widely different natural orders. The best description of true Rose-wood comes from Rio Janeiro, and is now said to be chiefly the produce of *Dalbergia nigra*, a tree belonging to the same section of leguminous plants as the present genus; but there are also several inferior sorts derived from the same country, and these are probably produced by different species of *Macherium*, three of which, viz. *M. armum*, *M. incurvabile*, and *M. legale*, are large trees, and, moreover, bear the same Brazilian name (Jacaranda) as the true Rose-wood. *M. Schomburgkii*, a British Guiana species, produces the beautifully mottled wood called Itaka, Itiki, or Tiger-wood, used for furniture in that country. [A. S.]

**MACHE.** (Fr.) The sand plants, *Faleria mella olitoria* and *coronata*.

**MACHOOTI.** An Indian name for *Polygonum aviculare*.

**MACKAYA bella** is a lovely shrubby plant forming a genus of *Acanthaceae*, dedicated by Harvey to Dr J. T. Mackay of Dublin. It is a native of the rocky bed of the Tongat river, Natal, and is described by its discoverer, Mr. J. Sanderson, as forming a beautiful object, being one mass of most delicate pendant pale lilac campanulate flowers, which grow in racemes four to six inches long. It belongs to the tribe *Asystasaceae*, and is nearly related to *Asystasia*, from which it differs in having two of the four stamens barren; and in the absence of a mucro at the base of the anther-cells. The name has also been bestowed upon an *Ulmaceae* tree of tropical Asia, but that is now referred to *Erythrapalum*. [J. Br.]

**MACLEANIA.** A genus of Peruvian shrubs, referred to the *Facelinaceae*. They have alternate leaves, and axillary flower-stalks terminated by a single flower, which has a five-winged calyx tube, a tubular co-

lla with ten monadelphous stamens attached to its base, and whose anthers are elongated into a tube, and an ovary adherent to the calyx tube, and with five many-seeded compartments. The flowers are reddish or yellow, and possess great beauty. The genus commemorates Mr. Maclean, a patron of Botany. [M. T. M.]

**MACLEAYA.** A genus of *Papaveraceae*, closely allied to *Bocconia*, but differing from it in the fruit, which is sessile and one-celled, with four to six seeds. The cotyledons of the embryo are three in number and equal, or two or four and then unequal, in size; in germination they are stalked. *M. cordata*, better known perhaps under its old name of *Bocconia*, is a handsome herbaceous plant frequently grown in English gardens, but native of China. The leaves are stalked, somewhat cordate, irregularly toothed at the margin, and glaucous. The flowers are borne in terminal panicles. The genus is named in honour of Mr. Maclean, colonial secretary in New South Wales. [M. T. M.]

**MACLURA.** This genus, which is peculiar to the western hemisphere—one species being found in the United States, one in Mexico, and five in Brazil and the West Indies—belongs to the *Moraceae*, and consists of middle-sized, sometimes spiny, deciduous trees, with smoothish entire or coarsely serrated leaves, and unisexual flowers upon distinct trees, the males being in cylindrical or globular spikes or in racemes, and the females forming dense globular heads. The fruits are numerous small seed-like achenes, enveloped in the enlarged calyxes, which are packed closely together upon the globose somewhat fleshy receptacle, so that the fruits of a single flower-head form a round aggregate fruit.

*M. aurantiaca*, the Osage Orange, is a native of the Southern United States, and forms a spreading tree from thirty to sixty feet high, but it is frequently kept dwarf and used as a hedge plant, for which purpose its strong spines render it suitable. It has large entire egg-shaped leaves, and inconspicuous yellowish-green flowers, producing large round fruits from three to five inches in diameter and of a fine golden colour, very beautiful to the eye, but scarcely eatable. Its elastic yellow wood is called Bow-wood, from its being used by the Indians for making bows.

*M. tinctoria*, the Fustic-tree, is a large usually unarmed tree, with nearly entire oblong taper-pointed leaves, a native of the West Indies and tropical America, from whence large quantities of its bright yellow wood are exported for the use of dyers, who obtain from it shades of yellow, brown, olive, and green. There are two kinds of Fustic, technically termed the Young and the Old, the former being the wood of *Rhus Cotinus*, and the latter that of the present plant. [A. S.]

**MACNABIA.** A genus of heathworts, distinguished by having the calyx four-cleft, two of the divisions keeled, the others

plain; eight stamens, with beardless anthers; and nearly circular flat winged seeds. The genus was named in honour of the late Mr. McNab, of the Edinburgh Botanic Garden. There is but a single species, a Cape shrub, with the habit of a henth, having leaves in whorls of three, and flowers solitary or in pairs, borne by the shorter branches. [G. D.]

**MACODES** *Palola* is a beautiful little orchid from Java, belonging to the group *Physoideae*. Its oval leaves are clouded on the upper surface, and elegantly marked with netted golden veins; but its flowers are small and inconspicuous, having free convolving green sepals and thread-like petals. As a genus, it is distinguished from *Myoda*, one of its closest allies, by its free lip; and from another, *Hemaria*, by its column having a two-lobed appendage at its base. [A. S.]

**MACOYA**. A Guiana name for *Acrocomia sclerocarpa*.

**MACRADENIA** *Intescens* is a little Trinidad orchid, forming a genus allied to *Oncidium*, from which it differs by its cucullate-concave undivided taper-pointed lip, by its free perianth divisions, by its column having the two lobes at its top converging into a hood, and by its two furrowless or minutely dented pollen-masses. The plant is only about four inches high, and has one-leaved pseudobulbs, from the base of which arises a stalk bearing a raceme of four or five dingy yellow flowers spotted with brownish purple. [A. S.]

**MACREA**. This name was given first to a Chilean genus of *Vicianaceae*, which proved to be identical with *Viriana*; and afterwards to a composite plant from the Galapagos Islands, which has since been reduced to *Lipochæta*. The former is now included by Benth and Hooker in the *Geraniaceae*, under which they place the *Virianææ*, as a minor group.

**MACRE**. (Fr) *Trapa natans*.

**MACROCEPHALOUS**. Big-headed: the term is sometimes applied to dicotyledonous embryos whose cotyledons are consolidated.

**MACROPODAL**. Big-footed: applied by Richard to the embryo of grasses, whose cotyledon was mistaken by that author for a radicle.

**MACROS**. In Greek compounds long; sometimes, large.

**MACROCHILUS**. The name of a small tree of the Sandwich Islands, forming a genus of *Lobeliaceae*, and described as having a straight trunk of ten to twelve feet in height, terminated by a crown of leaves and flower stalks, the former sharp-pointed and wavy, the latter longer than the leaves, drooping, and bearing the flowers in terminal globose heads, surrounded by densely overlapping bracts. The calyx tube is inversely conical, the limb five-cleft; the corolla has an elongated curved tube, cleft

on the upper side, and with a limb divided into five equal linear pendulous segments, whence the name of the genus, from *makros*, long, and *cheilos*, a lip. [M. T. M.]

**MACROCHLOA**. A genus of Grasses, belonging to the tribe *Stipeæ*, and included by Steudel in the genus *Stipa*, of which it forms a sub-section. *M. tenacissima*, a native of Spain and the North of Africa, is one of the sources of *Esparto* used for paper-making, &c. [D. M.]

**MACROCYSTIS**. A remarkable genus of dark-spored *Algae*, belonging to the natural order *Laminariaceae*. From a much-branched root springs, in the first instance, a small forked frond which alone bears the fruit in clouded patches, the endochrome of whose spore-cases ultimately breaks up into four spores, as in many other laminarioid *Algae*. Besides this, however, arise one or more tall slender stems, several feet in length, with a vertical terminal lanceolate frond, which is repeatedly split from the base upwards in such a way as to form new leaves, the attenuated base of which gradually passes into a short petiole, which becomes inflated above into a bladder. The original frond is thus repeatedly divided in a second manner, till the plant becomes hundreds of feet long. As, however, the stem does not increase in strength as the plant elongates, the strain is at length so great, notwithstanding the numerous bladders, that it at last gives way, and the plant floats. Many species have been proposed by authors, but all are reducible to one, *M. pyrifera*, which girds the

*Macrocytis pyrifera* var. *luxurians*.

southern temperate zone, and stretches up from thence along the Pacific to the Arctic regions, through 120 degrees of latitude. This plant, like the *Sargassum*, has been celebrated by all voyagers, to whom it is of great service in indicating the presence of rocks, acting, as it does, like a great buoy. Vast masses are thrown up on exposed coasts, where it is rolled by the waves till it forms cables as thick as a man's body. Single plants have been estimated on reasonable grounds as attaining a length of 700 feet. It is apparently indifferent to cold, if not extreme, but inasmuch as like

its near allies it is a deep-sea *Alga*, it requires a depth of at least six fathoms for its growth. [M. J. B.]

**MACROMERIA.** A genus of *Boraginaceae*, allied to *Lithospermum*, from which it differs by the exerted stamens, and by having the corolla with a long tube, dilated at the throat. They are Mexican strigose herbs, with simple stems, lanceolate serrated leaves, and terminal few-flowered bracteated racemes. [J. T. S.]

**MACROPIPER.** This word, signifying large pepper, is applied to a genus of *Piperaceae*, consisting of shrubs, natives of the islands of the Pacific, and having erect wavy knotted stems, alternate leaves on stalks that are dilated at the base, and provided with stipules, the blades of the leaves roundish or cordate with radiating venation. The male flowers are arranged in solitary catkins, the females in numerous catkins, placed in the axil of a leaf. *M. methysticum*, formerly called *Piper me-*

*Macropiper methysticum.*

*thysticum*, furnishes the root called by the Polynesians *Ava* or *Kava*, which has narcotic properties, and is employed medicinally in rheumatism and other complaints, but is chiefly remarkable for the value attached to it as a narcotic and stimulant beverage, of which the natives partake before they undertake any important business or religious rites. The approved method of preparing the *Kava* is to chew the root, and thus extract the juice. Dr. Seemann, in some letters from the Feejee Islands, printed in the *Athenæum* (1861), gives some amusing information concerning this plant and its uses. It appears that *Kava* has, like tobacco, a calming effect, rather than an intoxicating one, unless indeed the juice be fermented, as is done by the European residents in some of the islands of the South Sea. Dr. Seemann, however, tells us that the Feejeans pride themselves on the non-intoxicating properties of *Kava*, that it does not make the partakers quarrelsome, and that drunk in moderation it does not appear to have any ill effect upon the system, but when used in excess it produces numerous skin

diseases. All the lower classes of whites in Feejee are *Kava* drinkers, and most of them prefer the drink prepared in regular Polynesian fashion. The more respectable of the population refrain from touching the filthy preparation. Another species of this, or some allied genus, is used similarly in the formation of a beverage, differing from *Kava*, and having, according to Dr. Seemann, a flavour of soap-suds combined with jalap and magnesia. [M. T. M.]

**MACROPODIUM.** A genus of *Cruciferae*, allied to *Cardamine* and *Parrya*, from both of which it differs in the pod, which is oblong-linear with plane one-nerved valves, being stipitate. A perennial Alpine plant from the Altai, with a terminal raceme of white flowers. [J. T. S.]

**MACROBRYNCHUS.** A genus including about a dozen annual or perennial stemless herbs of the composite family, found in Oregon, California, and Chili. They have much resemblance to and affinity with *Taraxacum*, differing chiefly in the cylindrical ribbed achenes being destitute of any roughness, and being produced into a long beak, terminating in a pappus of numerous soft white hairs. [A. A. B.]

**MACROSTYLIS.** A genus of rutaceous shrubs, natives of the Cape of Good Hope, and nearly allied to *Barosma*. The distinctive characters reside in the presence of five stamens only, and in the three carpels, terminated at their points by a single style, longer than the stamens. The reddish flowers are arranged in a kind of umbel on the ends of the branches. The orchidaceous genus of this name is synonymous with *Corymbis*. [M. T. M.]

**MACROZAMIA.** A genus of *Cycadaceae*, consisting of Australian trees, living in swampy places near the sea. The genus is described as intermediate between *Cycas* and *Encephalartos*. The rachis of the leaves is twisted in the young condition, the leaflets themselves being flat. The male flowers are borne on spoon-shaped pointed spikes, the pollen being collected in two spaces on the under surface of the anthers, and not diffused over the whole surface as in *Encephalartos*. The female spikes bear only two flowers. [M. T. M.]

**MACULA** (adj. **MACULATE**, **MACULOSE**). A broad irregular spot or blotch.

**MACUSON.** (Fr.) *Lathyrus tuberosus*.

**MADAR**, or **MUDAR.** The produce of *Calotropis gigantea*.

**MADARIA.** A genus of *Compositae*, comprising two Californian annuals, closely allied to *Madia*, distinguished chiefly by the longer and more expanded ray florets, and by the florets of the disk being constantly sterile. The flower-heads form a loose terminal corymb with yellow florets.

**MADAROGLOSSA.** *Layia*.

**MADDER.** The root of *Rubia tinctoria*, which is sometimes called *Dyer's Madder*. —, **BENGAL.** *Rubia cordifolia*. —, **CHILI.**

*Rubia* Rollson. —, FIELD. *Sherardia arvensis*. —, INDIAN. *Oldenlandia umbellata*. —, WILD. *Rubia peregrina*.

**MADDERWORTS.** A name for the *Galearacea*.

**MADHUCA, or MADOOKA.** *Bastia butyracea* and *latifolia*.

**MADIA.** A coarse hairy more or less viscosus erect annual, forming a genus of *Compositae* of the tribe *Helianthae*. The lower leaves are opposite and entire, the upper ones alternate; and the flower-heads nearly globular, in a terminal raceme, with yellow florets. The involucrel bracts are in a single series, each one folded so as to enclose one of the ray florets, which are ligulate or irregularly enlarged; between these and the disk is a single row of scales, but the centre of the receptacle, bearing the tubular disk florets, is entirely without scales. The achenes are flattened, without any pappus. *M. sativa*, the only species known, is a native of Chili and of North California, and is there cultivated for the oil extracted from its seeds.

**MADOORKATI.** An Indian name for *Cyperus Pangoret*, from which Indian matting is made.

**MADOTHECA.** A genus of *Jungermanniaceae*, belonging to the division *Platyphyllae*, which has incubous leaves with the lower lobe simply folded upon the upper, an involucre of the same shape as the leaves, and a perianth neither winged nor angular as in *Frullania*. The lobes do not throw out roots from their under surface, as in *Radula complanata*. *M. platyphylla* forms elegant tufts upon old wall-tops, and is very common. [M. J. B.]

**MADWORT.** *Alyssum*; also *Asperugo procumbens*. —, GERMAN. *Asperugo procumbens*.

**MÆRUA.** A genus of *Cyperidaceae*, consisting of small shrubs, natives of tropical Africa, Arabia, and India. The flowers have a funnel-shaped calyx, the tube of which is persistent, while the limb is divided into four equal deciduous segments. There is no corolla, but standing up from the throat of the calyx is a short crown deeply and irregularly divided. The stamens are very numerous, on an elongated receptacle; and the pod is one-celled. [M. T. M.]

**MÆSA.** A genus of *Myrsinaceae*, consisting of trees or shrubs with alternate entire or toothed leaves, and small flowers in simple or compound racemes, either axillary or very rarely terminal. It is distinguished from all others of the order by the ovary, which is wholly or partially inferior. There are several species, natives of the tropical regions of Africa, Asia, and Australia, but none of them present any special interest.

**MAFUNA.** A vegetable wax, suitable for making candles, obtained in Mozambique from a tree whose native name is *Mutiana*.

**MAGHET.** *Pyrethrum Parthenium*, and many other ray-flowered *Compositae* with white ray-florets.

**MAGALLANA.** A plant described by Cavanilles as forming a genus of *Propagolaceae*, and inhabiting Central America in the neighbourhood of Port Desire. Benthams and Hooker, however, state their conviction that the figure illustrating the supposed genus has been made from a depauperated specimen of *Propagolum pentaphyllum*, to which has been added some alien fruit. This supposition is strengthened by an obvious inaccuracy in the position of the fruit, and by the fact that *P. pentaphyllum* is abundant in the places where *Magallana* is said to grow. [J. Br.]

**MAGNOLIACEÆ.** (*Magnolia*, *Wintera*, *Illiciæ*.) A natural order of dicotyledonous plants belonging to Lindley's natural alliance of hypogynous Exogens. Trees or shrubs with alternate leathery sometimes dotted leaves, and convolute stipules which cover the buds and are deciduous. Flowers fragrant; sepals usually three to six, deciduous; petals three or more, imbricated; stamens numerous, distinct, with adnate anthers; carpels one-celled, numerous, on an elevated receptacle. Fruit of numerous dry or succulent dehiscent or indehiscent carpels; seeds often arillate, and suspended from the fruit by a long funiculus; albumen fleshy homogeneous; embryo minute. *Magnolias* abound in North America. They possess bitter, tonic, and aromatic qualities. *Drims Winteri* yields Winter's bark. *Illicium anisatum* is called star-anise, from its flavour, and the star-like arrangement of its carpels. *Liriodendron tulipifera*, the tulip-tree, is remarkable for its truncate leaves. There are about a dozen genera, and upwards of seventy species. Examples: *Magnolia*, *Drims*, *Liriodendron*. [J. H. B.]

**MAGNOLIA.** Few botanists have their name and fame commemorated so splendidly as a genus of plants as that which derives its title from Pierre Magnol, Professor of Medicine and Botany, at Montpellier, in the latter part of the seventeenth and beginning of the eighteenth century. The genus gives its name to the order *Magnoliaceae*, and consists for the most part of large trees with fine foliage, and handsome fragrant flowers. They are natives of the southern states of North America, of Northern India, China, Japan, and other parts of Asia. The leaves are alternate, entire, deciduous or evergreen, rolled round in the bud, in which state they are protected by the stipules, which originally adhere to the sides of the leafstalks, but ultimately fall off. The flowers are large, terminal, protected in the young state by scales that seem to be of a stipulary nature, as the writer has not unfrequently seen a leaf developed from them in the same manner and in the same situation as with the scales of the leaf-bud, which are acknowledged to be stipules. Moreover, Drs. Hooker and Thomson describe one species, *M. Campbellii*, as having constantly these leaf-bearing scales surrounding the flower. The calyx consists of three deciduous sepals; the corolla of six to twelve petals like the sepals; stamens and ovaries numerous, on

a prolonged receptacle. The fruit consists of a number of foliicles, in a compact spike, and opening along their outer edge to allow of the escape of the scarlet or brown seeds, which are suspended from the carpels by long slender threads.

Most of the species have aromatic tonic properties, which has led to their employment in fevers, rheumatism, and other complaints. The beauty of the foliage and flowers of these trees gives them yet greater claims to our regard than their medicinal properties, which, although not slight, are excelled by those of other plants. The noblest of all is perhaps *M. grandiflora*, a native of North Carolina, where it forms a tree sixty to one hundred feet high. In this country it is commonly grown against a wall, and has generally proved hardy in the south of England, in such a situation, with little or no other protection. But the severe winter of 1860-61 proved fatal in many cases to this, as to so many other reputedly hardy plants. The leaves of this species are evergreen, nine to ten inches long, much like those of a cherry-laurel, but rusty-brown on the under surface. The flowers are large, cup-shaped, white or pale lemon-coloured, and having an exquisite fragrance; they bloom in the latter part of the summer, and occasionally produce their rich brown spikes of fruit in October. There are several varieties of this tree in cultivation, differing in the shape of the leaves, the period of flowering, &c.

*M. glauca* is a low-growing deciduous tree, called in America Swamp Sassafras, from the nature of the localities in which it grows, and from the resemblance in its properties to *Laurus Sassafras*. It is also known by the name of Beaver-tree, because the root is eaten by beavers, which animals also make use of the wood in constructing their nests. *M. tripetala* has very large leaves and flowers, the latter with so potent a perfume as to produce sickness; fever and gout even have been attributed, doubtless erroneously, to the strong smell of the flowers. The young wood is of a dark brown colour. *M. acuminata* and *M. Fraseri* are called Cucumber-trees in America, on account of the appearance of the unripe fruit. *M. conspicua*, or *M. Yulan*, is a tree attaining a height of forty to fifty feet in China, but not more than half that height in this country. It is remarkable for producing its white flowers in spring, before the leaves are developed. *M. purpurea*, a Japanese species, has deciduous leaves and fragrant flowers, the outer segments of which are purple, the inner white. It forms a splendid bush in the south of England. *M. Campbellii*, a native of Sikkim, is described by Dr. Hooker as a superb species, flowering before the leaves appear, and attaining a height of 150 feet.

There are a few species and varieties that need the protection of a greenhouse in this country; that most frequently met with is *M. fuscata*, a low-growing shrub with evergreen leaves, and dull purple flowers of exquisite fragrance. [M. T. M.]

**MAGONIA.** A genus of *Sapindaceae*, consisting of two trees, natives of Brazil, occupying extensive tracts of land to the exclusion of other trees, and forming what the Brazilians term *Catingas*, i.e. woods consisting entirely of deciduous trees. They are middle-sized trees, with abruptly pinnate leaves, and large panicles of perfect and imperfect flowers mixed together, appearing before the leaves. The fruit is a large woody three-sided three-celled capsule, containing six or eight broad flat winged seeds in each cell, and opening longitudinally through the middle of the cells when ripe.

*M. glabrata*, which usually attains the height of thirty or forty feet, covers tracts of land some miles in extent in the province of Ceara. It is called *Tingi* by the Brazilians, who employ an infusion of the bark of its root for poisoning or stupefying fish, while that of the bark of the stem they use for curing old ulcers, or the sores in horses caused by the stings of venomous insects. From the broad flat seeds they manufacture a kind of soap, which answers very well for washing clothes; it is prepared by soaking the seeds in water until they are soft, and then boiling them with a small quantity of tallow, till a homogeneous mass is formed. [A. S.]

**MAGUAY, or MAGUAY DE COCUTZA.** *Agave americana*. — DE COCAY. *Agave cubensis*. — METL. *Agave americana*, and *A. mexicana*.

**MAGYDARIS.** An umbelliferous genus of one or two species, found in Spain, Sicily, and North Africa, technically distinguished from *Conium* by its seeds being covered on both sides with numerous very thin vittæ. They are hoary plants, with pinnately cut leaves, the segments of which are lobed and toothed. [A. S.]

**MAHALEB.** (Fr.) *Cerasus Mahaleb*.

**MAHARANGA.** The three species forming this genus of *Boraginaceae*, at one time included in *Onosma*, are small hairy or bristly herbaceous plants, natives of Northern India, with entire leaves and terminal racemes of clustered flowers. These latter have a five-parted calyx, and a corolla with a short cylindrical tube widened out suddenly, and having five deep longitudinal furrows, and as many clefts round the closed mouth, the inside of the tube above its insertion being furnished with a plated coronet, which distinguishes the genus from its congeners.

The Nepalese apply the name *Maharanga* to *M. Buxodi* only, but botanists have adopted it as a generic name. The word is said to signify 'a strong or intense colour,' in allusion to the dyeing properties of the roots. These are thick, and of a tapering form, of a deep purple colour outside, and yield a brilliant red to oil, but only a dirty brown to water; they are the same as the Rutton root of the Indian bazaars, used for colouring oils for staining wood of a mahogany colour. [A. S.]

**MAHERNIA.** A genus of *Sterculiaceae* only differing from *Hermannia* in the filaments of the stamens being dilated in the middle; also very slightly in the inflorescence, the peduncles being usually two-flowered and terminal or opposite to the leaves. There are above thirty species, all, like the majority of *Hermannia*, natives of the Cape Colony.

**MAHLIB.** The fragrant kernels of *Cassia Muhaleb*, which are strung as necklaces, and much valued by the women of Scinde and other parts of India.

**MAHOE.** *Paritium lilaceum*; also *Sterculia caribaea*. —, BLUE or COMMON. *Paritium elatum*. —, BOMBAST. *Ochroma Lagopus*. —, CONGO. *Hibiscus clypeatus*. —, GREY or MOUNTAIN. *Paritium elatum*. —, NEW ZEALAND. *Melicope ramiflorus*. —, SEASIDE. *Thespesia populnea*.

**MAHOE-PIMENT.** *Dephlopsis caribaea*.

**MAHOGANY.** *Swietenia Mahagoni*. —, AFRICAN. *Khaya senegalensis*. —, BASTARD. *Ratonia apatala*. —, BAYWOOD. A Honduras name for *Swietenia Mahagoni*. —, EAST INDIAN. *Soyimida febrifuga*. —, INDIAN. *Cedrela Toona*. —, MOUNTAIN. *Betula lenta*. —, MADEIRA. *Persea indica*. —, SENEGAL. *Khaya senegalensis*. —, SPANISH. *Swietenia Mahagoni*. —, QUEENSLAND SWAMP. *Angophora*. —, WHITE or WILD. *Stenostomum bifurcatum*.

**MAHONILLE.** (Fr.) *Malcolmia maritima*.

**MAHOREE.** A Bengal name for Antiseed.

**MAHYA-TREE.** *Bassia butyracea* and *latifolia*.

**MAI-DENG.** A hard heavy red wood of Siam, well adapted for furniture.

**MAIDENHAIR-TREE.** *Salisburia adiantifolia*.

**MAIDEN-LIP.** *Echinoppermum Lappula*.

**MAID'S-HAIR.** *Galium verum*.

**MAIMUNNA.** A fruit-bearing rhamnoid of Afghanistan.

**MAIS.** (Fr.) *Zea Mays*. — DE GUINÉE. *Milium nigrificans*.

**MAI-TAKLOU.** A heavy timber of Siam, supposed to be that of *Nauclea orientalis*, considered to be incorruptible, and bearing a sacred character from being much used in the construction of temples.

**MAI-TIKIEN.** A valuable timber of Siam, obtained from *Metrosideros vera*.

**MAITHES.** *Pyrethrum Parthenium*. —, RED. *Adonis autumnalis*.

**MAIZ DEL AGUA.** *Victoria regia*.

**MAIZE.** *Zea Mays*. —, WATER. *Victoria regia*.

**MAIZENA.** A fine flour prepared from the Maize or Indian corn, *Zea Mays*.

**MAJOE-BITTER.** *Piermania Antidesmia*.

**MAJOON.** A confection of Hemp, being a compound of butter, sugar, flour, milk, and bhang.

**MAJORANA.** *Origanum Majorana*, the Sweet Marjoram.

**MAKANA.** An Indian name for *Euryale ferox*.

**MAKEBATE.** *Polemontium caruleum*.

**MAKKER, or MAKER.** An Abyssinian name for *Boscovelia papyrifera*.

**MALABAR LEAF.** *Cinnamomum malabathrum*.

**MALACH.** A Turkish name for Hemp, *Cannabis sativa*.

**MALACHADENIA clavata.** An orchid from Rio de Janeiro, of which Mr. Batesman remarks: 'It is the only epiphyllal orchideous plant I know which emits a positive stench, and that too at all hours by night and day. In the stove it resembles the foulest carrion.' It is the only species of the genus, and has a creeping rhizome bearing one-leaved pseudobulbs, and slender scapes with five or six small greenish brown-spotted flowers turned upside down. These latter have the side sepals joined, except at their reflexed apices, and the other one large, heart-shaped, and pointed; extremely minute petals; a fleshy ovate reflexed lip, articulated with the column, which has a prolonged foot and two cirri in front; and two waxy pollen-masses sessile on a large soft cubical gland. [A. S.]

**MALACHIUM.** A genus of *Caryophyllaceae*, founded on *Cerastium aquaticum*. It differs from *Cerastium* in having the capsule ovoid, and the teeth joined in pairs; and from *Stellaria*, of which it has the habit, by the latter character, and by having five styles. *M. aquaticum* is a common English plant, resembling chickweed, but larger; and also *Stellaria nemorum*, but the flowers are not so large, and the ovate leaves have shorter stalks. [J. T. S.]

**MALACHODENDRON.** *Stuartia Malachodendron*.

**MALACHRA.** A genus of malvaceous plants, consisting of herbs or undershrubs, natives usually of marshy places in tropical regions. The stems have lines of hairs running down them, and the leaves are likewise covered with pungent hairs, while the yellowish flowers are grouped in heads, surrounded by an involucre. The calyx is five-cleft, the corolla five-petaled, the staminal tube divided into about twenty filaments, the ovary five-lobed and five-celled, and the fruit of five carpels. [M. T. M.]

**MALACOID.** Having a mucilaginous texture.

**MALAPOO.** The dried flowers of *Cedrela Toona*.

**MALAGUIE.** (Fr.) *Malachium*.

**MALAXIS** *pubescens* is a small delicate terrestrial orchid, forming of itself a genus, distinguished from *Liparis* by the proportion of the petals, and by the pollen-masses, which are club-shaped, in two pairs, both suspended from a gland which terminates the column. It grows to three or four inches in height, the rootstock producing a small solid bulb out of the ground, and three or four ovate or oblong leaves. The flowers are very small, of a greenish-yellow, in a loose slender raceme. It grows in spongy bogs in Northern Europe and Asia, and is sparingly dispersed over a great part of Britain.

**MALCOLMIA**. A genus of herbaceous plants, mostly annuals, belonging to the cruciferous order, and distinguished by having a roundish pod, and a simple pointed stigma. The species are mostly natives of the south of Europe, and agree in having roughish toothed or sinuated leaves, and purplish or white flowers disposed in racemes, and destitute of bracts. [C. A. J.]

**MALESHERBACEÆ**. (*Crownworts*.) A natural order of dicotyledonous plants, belonging to Lindley's violal alliance of hypogynous Etoeans. Herbs or half-shrubby plants, with alternate exstipulate leaves, and solitary yellow or blue flowers. Calyx tubular, five-lobed, inflated; petals five, convolute in aestivation, persistent, arising outside a short membranous rim or corone; stamens five to ten, perigynous, with versatile anthers, the filaments often connected with the stalk of the ovary; ovary superior, stalked, one-celled, with parietal placentas; ovules numerous, pendulous, anatropal; styles three, the stigmas club-shaped; fruit a one-celled three-valved capsule; albumen fleshy. These plants, found in Chili and Peru, are allied to the passion-flowers. The two genera, *Malesherbia* and *Gynopleura*, contain about half a dozen species. [J. H. B.]

**MALESHERBIA**. One of the two genera of *Malesherbaceae*, and consisting of two or three species, small pubescent shrubs, natives of Peru, with long narrow deeply sinuate-toothed leaves, and yellow sessile flowers, solitary in the leaf-axils, but forming a long raceme or thyrses. It is distinguished from its ally by its long cylindrical tubular calyx, and by the corona at the mouth of the calyx being deeply ten-lobed, with truncate denticulate lobes. [A. S.]

**MALE SYSTEM**. All that part of a flower which belongs to the stamens.

**MALHERBE**. (Fr.) *Plumbago europæa*; also *Thapsia villosa*.

**MALICOIRUM**. An old name for the woody rind of the pomegranate fruit, used medicinally.

**MALKUNGUNEE**. An Indian name for *Celastrus paniculatus*.

**MALLEA** *Rothii* is the sole representative of a genus of *Meliaceae* peculiar to the East Indies. It is a shrub with impari-pinnate leaves, axillary paniculate or

racemose flowers, a cup-shaped five-toothed calyx, five lanceolate petals, ten stamens, and a fleshy drupe containing five stony kernels. Uses unknown. [B. S.]

**MALLER**. The native name of *Eucalyptus dumosa*, which forms the dreary Mallee scrub of South Australia. — of Victoria. *Eucalyptus oleosa*.

**MALLEOLUS**. A layer; a shoot bent into the ground and half divided at the bend, whence it emits roots.

**MALLETT**. (Fr.) *Capsella Bursa-pastoris*.

**MALLOW**. *Malva*; also *Malvastrum*. —, **GLADE**. *Napæa*. —, **GLOBE**. *Sphaeralcea*. —, **INDIAN**. *Sida*; also *Urena*, and an American name for *Abutilon*. —, **JEW'S**. *Corchorus olitorius*, and *C. capsularis*. —, **MARSH**. *Athaea officinalis*. —, **TREE**. *Lavatera arborea*. —, **VENICE**. *Hibiscus Trionum*.

**MALLOWWORTS**. Lindley's name for the *Malvaceae*.

**MALOO CREPPER**. An Indian name for *Bauhinia racemosa*.

**MALOPE**. A genus of herbaceous plants belonging to the *Malvaceae*, and closely allied to *Malva*, from which it may be distinguished by the broadly cordate leaflets of the calyx. *M. trifida* is an annual from North Africa, growing about two feet high, bearing during the whole of summer large deep rose-coloured or white flowers. *M. grandiflora* is taller and more robust, with larger flowers. [C. A. J.]

**MALORTIEA**. There are three species of this genus of palms, all natives of Central America. They have slender reed-like

*Malortia simplex*.

stems, long-stalked irregularly pinnate or sometimes simple jagged leaves, and simply branched spikes of unisexual flowers

springing from the axils of the lowermost leaves, and producing small roundish or egg-shaped one-seeded fruits. Two Guatemalan species, *M. gracilis* and *M. simplex*, are cultivated in our hothouses. [A. S.]

**MALPIGHIACEÆ.** (*Nitrariaceæ*, Malpighiada.) A natural order of dicotyledonous plants belonging to Lindley's sapindal alliance of hypogynous Exogens. Trees or shrubs, sometimes climbing, with simple opposite or very rarely alternate stipulate leaves, without dots; hairs, when present, petiole. Flowers either perfect or unisexual; sepals five, slightly united, persistent, often glandular at the base; aestivation imbricated; petals five, unguiculate, with convolute aestivation; stamens usually ten, often monadelphous, the anthers roundish, with a projecting process from the connective; ovary formed by three (rarely two or four) carpels, more or less combined; ovules solitary, with a long pendulous cord; styles three, distinct or united. Fruit dry or fleshy, sometimes winged; seeds solitary, orthotrupal, suspended, exalbuminous; embryo straight or curved in various ways; cotyledons foliaceous or thickish. They are inhabitants of tropical countries chiefly, and a great number of them are found in South America. *Malpighia*, *Banisteria*, *Hiptage*, *Hircea*, and *Gaudichaudia*, offer examples of the forty-five genera, which contain nearly 600 species. [J. H. B.]

**MALPIGHIA.** A genus of tropical American shrubs, with opposite leaves, either entire or slightly toothed, not infrequently having petiole, and sometimes stinging hairs. The flowers are of a reddish-yellow or white colour, usually grouped in axillary or terminal tufts, the stalks themselves jointed and bracteate. The calyx is five-cleft, some of the segments having two glands at their base; petals five, longer than the sepals, stalked; stamens ten, all fertile, united into a tube at the base; ovary three-celled, each cell with a single pendulous ovule; styles three, distinct. Fruit fleshy, with three crested stones. The genus derives its name from Malpighi, a celebrated Italian anatomist, one of the first to employ the microscope in physiological researches. He was Professor of Medicine at Bologna in the latter part of the seventeenth century. The order *Malpighiaceæ* takes its name from this genus. The fruits of *M. glabra* and *M. urens* are eaten in the West Indies, those of the latter being called Barbados Cherry. Some of them are of twining habit, and the singularity of their flowers renders them desirable in our hothouses. [M. T. M.]

**MALT.** Barley which has been steeped in water so as to excite germination, and then kiln-dried.

**MALVACEÆ.** (*Mallowworts*.) A natural order of dicotyledons belonging to Lindley's malval alliance of hypogynous Exogens. Herbaceous plants, trees, or shrubs, with alternate stipulate leaves more or less divided, and often with stellate hairs. Sepals

five, rarely three or four, more or less cohering at the base, with a valvate aestivation, often bearing an external calyx (epicalyx) or involucre; petals equal in number to the sepals, with twisted aestivation; stamens indefinite, hypogynous, all perfect, their filaments monadelphous or polyadelphous, and the anthers monothechal, reniform, with transverse dehiscence; ovary formed by the union of several carpels round a common axis, either distinct or cohering; styles as many as the carpels, united or free. Fruit capsular or baccate; carpels one or many-seeded, sometimes closely united, at other times separate or separable, their dehiscence loculicidal or septicidal; albumen none, or in very small quantity; embryo curved; cotyledons twisted or doubled. Found in tropical countries and in the warm parts of temperate regions. They are mucilaginous and demulcent, and yield fibres. *Aithæa officinalis* (marsh mallow) yields mucilage. *Gossypium* furnishes various kinds of cotton. *Hibiscus cannabinus* supplies Indian hemp. *Parlatum elatum* gives Cuba bast. There are nearly fifty genera, including *Malva*, *Lavatera*, *Hibiscus*, and *Sida*, and upwards of one thousand species. [J. H. B.]

**MALVA.** The typical genus of *Malvaceæ*, embracing a large number of species widely spread through the northern hemisphere, being found in most European countries, in Northern and Central Asia, and in North America, while the few species belonging to the southern hemisphere are confined to South Africa. These numerous species differ greatly in appearance, some being small annual or perennial herbaceous plants, others shrubs of variable height, but they all agree in possessing tough fibre, and an abundance of mucilage. Their flowers, which are frequently very showy, but of short duration, have an outer calyx or involucre, consisting of three distinct leaves attached to the lower part of the true calyx, which is more or less deeply cut into five broad lobes; and the numerous single-seeded carpels are disposed in a circle round a central axis, but become detached when ripe.

*M. moschata*, the Musk Mallow, derives its name from the peculiar musky odour given off by all parts of the plant when kept in a confined situation, particularly in warm dry weather, but it is seldom powerful enough to be smelt in the open air. The plant is a perennial, and has large rose-coloured flowers clustered together at the ends of the erect slightly branched stems. It is found along hedges, roadsides, and borders of fields in the British Isles. *M. rotundifolia* is an annual, with tough downy stems lying upon the ground, and has roundish lobed leaves, and small pale-bluish flowers clustered in their axils. It is common in waste places in most parts of Europe, including Britain, and in Western Asia. In Egypt, especially upon the banks of the Nile, it is extensively cultivated, and used by the natives as a pot-herb. *M. sylvestris*, the Common

Mallow, or *Mauve* of the French, is employed medicinally on account of its highly mucilaginous properties, a decoction of it being used as an outward application to bruises, and internally in dysentery. It is in great repute amongst herb-doctors and rustic practitioners generally, particularly in France, where its dried flowers are largely used in the preparation of a drink called *Tisane*, or *Ptisan*, held to be a cure for headache, feverish colds, and many other complaints; its leaves are also made into poultices. It is a biennial, spread through Europe and Russian Asia, having erect somewhat hairy stems, roundish long-stalked leaves, and reddish-purple flowers. [A. S.]

**MALVASTRUM.** A genus of *Malvaceæ*, consisting of Amer. can. herbs with axillary scarlet or orange flowers, usually solitary, but rarely clustered. Calyx usually unprovided with any involucrel, but sometimes with a few deciduous hairy bracts, or three persistent leafy bracts; tube of the stamens simple; stigmas button-shaped, small; carpels with or without a beak. [M. T. M.]

**MALVAYISUS.** A genus of *Malvaceæ*, consisting of shrubs, with entire or slightly lobed leaves, and crimson flowers. The calyx is surrounded by a many-leaved involucre; petals erect; stigmas ten; carpels five, berry-like, one-seeded, slightly separated one from the other, or more generally combined into a five-celled fruit. The species are natives of tropical America and Mexico. [M. T. M.]

**MALVO DO CAMPO.** The Brazilian name of *Kleinmeyeria speciosa*.

**MAME.** The seeds of *Soja hispida*.

**MAMILLA.** The apex of the nucleus of an ovule.

**MAMILLARIA.** Mexico may be looked upon as the head-quarters of this genus of *Cactaceæ*, the great majority of the species being confined to that country, comparatively few belonging to Southern California, Guatemala, Texas, Louisiana, and Missouri; some, however, are indigenous to South America, and are found as far south as Buenos Ayres and Chili. The genus is, in most instances, readily distinguished from its allies by the fleshy stem, of which the plants solely consist, being entirely covered with tubercles of a teat-like form, giving rise to the generic name, from *mamilla*, a little teat. These are disposed in a series of spirals, each teat being furnished at the top with a tuft of radiating spines proceeding from a kind of cushion. The entire plants assume various forms, some species being more or less cylindrical, others nearly round, some pear-shaped, and others club-shaped, but the majority seldom exceed six or eight inches in height. The flowers are produced towards the summit of the plants, and usually in a transverse zone, each flower growing from the axil of one of the teats; they are white, yellow, or of different shades of red or rose-colour, and remain open only during the day, closing at night and opening again

the following morning. They have the tube prolonged beyond the ovary, smooth and contracted below; the numerous segments in several series, the outer or calycine ones being smaller than the inner or petaline; and the stamens, which are also in several series, grow to the inside of the tube, being shorter than the thick style, which is terminated by a three to seven-rayed stigma. The fruit is an oblong or club-shaped smooth berry, containing numerous small seeds.

*M. Clava* is a native of Mexico, and is columnar or club-shaped, attaining a foot or more in height, with the mamillæ large, projecting, and of a pyramidal form, with bluntly-angled sides, and having tufts of white wool between them, and likewise upon their summit. The straw-coloured flowers are very large and showy. *M. coronaria* is the tallest species of the genus, growing, it is said, as high as five feet. In our gardens, however, it is seldom more than a foot high and three inches thick, of a cylindrical form, with large conical mamillæ bearing from thirteen to sixteen pellucid white spines radiating from a little tuft of white wool, and four inner brown ones. The flowers are of a fine crimson colour. *M. pusilla* is a very pretty little species, growing in crowded tufts usually of a hemispherical shape. The mamillæ, which are about the size of grains of wheat, have little tufts of white hairs between them, and bear bundles of spines, consisting of from four to six straight stiff inner ones, and from twelve to twenty outer ones like white hairs; the flowers are yellow tinged with rose-colour, and are succeeded by beautiful bright crimson berries about the size of the mamillæ. [A. S.]

**MAMMEFORM, MAMMILLARIS.** Teat-shaped; conical, with a rounded apex.

**MAMMEA.** A genus of *Clusiaceæ*, characterised by the globular calyx, which opens in two valvate sepals; by the ovary, which contains four ovules, distributed into two or four cells; and by the fruit, which is an indehiscent drupe, containing one to four large seeds with very thick almost consolidated cotyledons and a very short radicle. The principal species, and the only American one, is the *M. americana*, a large tree, with opposite coriaceous leaves marked with very numerous transverse but reticulated veins, and with pellucid dots, and bearing white sweet-scented showy flowers on short peduncles, solitary or clustered in the lower axils of the young shoots. The fruit, known under the name of Mammee Apple, or South American Apricot, is very much esteemed in tropical countries. It often attains the size of a child's head, and is of a yellow colour. The outer rind and the pulp which immediately surrounds the seeds are very bitter, but the intermediate flesh is sweet and aromatic, and is eaten cut into slices and steeped in wine, or made into preserves of various kinds. The seeds, often as large as hen's eggs, are used as anthelmintics; an aromatic liqueur called *eau de créole* is distilled

from its flowers; and the acrid resinous gum distilled from its bark is used to destroy the chiggers, little insects that attack the naked feet of the negroes. The tree is a native of the West Indies and of continental tropical America, but is cultivated for its fruit and almost naturalised in some parts of tropical Africa and Asia. The genus is now sometimes made to include two or three tropical Asiatic species, with smaller flowers and fruits, but similar in structure, which had previously been published under the name of *CALYSAOCCION*: which see.

**MAMMEE.** *Lucuma mammosum*.

**MAMMEE-TREE.** *Mammea americana*.

**MAMMOTH-TREE.** *Wellingtonia gigantea*.

**MANA.** An Indian name for *Paspalum acrobiculatum*.

**MANACÁ.** A Brazilian name for *Franciaea uniflora*.

**MANAWA.** A New Zealand name for an aromatic resin reputed to be obtained from *Avicennia tomentosa*.

**MANOHINEEL.** The virulently poisonous *Hippomane Mancinella*. —, **BASTARD.** *Cameraria latifolia*.

**MANCIENNE.** (Fr.) *Viburnum Lantana*.

**MANCUS.** Deficient in something; wanting.

**MANDAVALLI.** An Indian name for the purgative *Convolvulus reptans*.

**MANDEVILLA.** A genus belonging to the order of dogbanes, distinguished by its calyx having internally a pectinate ring; by the five stamens enclosed in the corolla, their anthers lanceolate, membranaceous at the top, and forming a cone round the stigma; and by the single style, its stigma conical, five-lobed below. The only species is a climbing shrub, a native of Buenos Ayres, whence it was first introduced, under the name of Chili Jasmine; its large pure white and sweetly scented flowers render it an acquisition to collections. Named after H. J. Mandeville, H.B.M. minister at Buenos Ayres. [G. D.]

**MANDIOC.** *Manihot utilisatima*, from which cassava is prepared.

**MANDIROLA.** A Brazilian gesneriad, related to *Achimenes*, the typical species being the plant known as *Achimenes multiflora*. It is characterised by its scaly stolones, by its subcampanulate corolla with a spreading fringed limb and narrow base, by its crenated membranaceous perigynous ring, and by its two-lobed stigma. *M. lanata* is now called *Eucodonia*. [T. M.]

**MANDOBI, MUNDUBL.** Portuguese names for *Arachis hypogea*.

**MANDRAGORA.** This name, derived from two Greek words implying hurtful to cattle, is applied to a genus of *Solanaceae* or *Atropaceae*. The species are natives of

Southern Europe and the East, and have very short stems, with a thick fleshy often forked root, from the summit of which the entire ovate lance-shaped leaves appear to proceed in compact tufts. The flower-stalks spring from among the leaves, and bear a solitary flower with a top-shaped calyx, a bell-shaped corolla, to the base of which are attached five stamens, whose filaments are dilated above their base. The fruit is fleshy, one-celled, from the breaking up of the partition between the two original cells of the ovary, and supported by the slightly enlarged and persistent calyx.

The Mandrakes, like their near ally *Beladonna*, have poisonous properties. They act as emetics, purgatives, and narcotics, and would seem to have been much used as sedatives in olden times, though now disused. Shakspeare is supposed to allude to this plant when he makes Banquo, in *Macbeth*, say: 'Or have we eaten of the insane root that takes the reason prisoner?' And also in *Antony and Cleopatra*: 'Give me to drink Mandragora.' Dr. Silvester has shown that Mandrake was employed in olden times as an anæsthetic, in the same way that chloroform now is.

In the days when the doctrine of signatures was an article of faith among the ignorant at least, the Mandrake root, from its occasional similarity to the lower part of the human figure, was considered to possess great virtues, and was in constant use for amorous incantations and love philtres. Its use in this manner is alluded to in *Genesis*, chap. xxx. (the Dudaim being identified with the Mandrake); and the superstition, kept alive by the craft and ingenuity of the charlatan, has not entirely died out even at present, although the root of *Bryonia dioica* is now employed under the erroneous name of mandrake. Nor was this the only superstitious notion connected with this plant, for Josephus mentions that its chief use is to dispel demons, who cannot bear either its smell or its presence. Shakspeare also alludes to the fanciful belief entertained as to this plant, in the following passage from *Romeo and Juliet*:—

And shrieks like mandrakes torn out of the earth,  
That living mortals, hearing them, run mad.

Josephus even relates that it was certain death to touch this plant, except under certain circumstances, which he details (*Wars of the Jews*, book vii. cap. vi.). The same writer mentions that it was taken without danger, in the following manner: 'They dig a trench quite round about it, till the hidden part of the root be very small; they then tie a dog to it, and when the dog tries hard to follow him that tied him, this root is easily plucked up, but the dog dies immediately, as if it were instead of the man that would take the plant away; nor after this need any one be afraid of taking it into their hands.' Dioscorides mentions a male and female kind of Mandrake, which apparently correspond with the spring and autumnal species of modern botanists. In Professor Daubeny's interesting lectures on Roman husbandry, is a plate copied from

the most ancient MSS. of Dioscorides, now at Vienna, 'representing Euresis, the goddess of discovery, presenting in triumph to Dioscorides the root of this mandrake, which she has just had pulled up, whilst the unfortunate dog which had been employed for that purpose is depicted in the agonies of death;' and in some other MSS. of this author, which the writer has had the opportunity of inspecting, representations are given of the mode of extracting male and female mandrakes from the

*Mandragora autumnalis.*

ground, in the manner before related from Josephus. Indeed, in old herbals similar illustrations are not uncommon. Of the two species previously mentioned, *M. officinarum* or *M. autumnalis* is a very handsome autumn flowering plant, with wavy leaves, and deep blue flowers. [M. T. M.]

**MANDRAKE.** *Mandragora*; also an American name for *Podophyllum*.

**MANETTIA.** A genus of *Cinchonaceae*, so called in honour of Xavier Maunet, Professor of Botany in Florence in the middle of the eighteenth century. The species are undershrubs of climbing habit, natives of tropical America. They have opposite leaves and wide stipules; axillary one or many flowered flower-stalks; a turbinate calyx, with the limb divided into four or five linear lance-shaped lobes, with an equal number of teeth between them in some cases; and a funnel-shaped corolla dilated and hairy at the throat, the limb divided into four or five obtuse segments. There are four or five stamens inserted into the throat of the corolla, and slightly protruding; and a thread-like style. The rind of the root of *M. cordifolia* has emetic properties, and is used by the Brazilians in dropsy and dysentery. Two or three species with scarlet or pink flowers are grown in hot-houses in this country. [M. T. M.]

**MAN FUNGUS.** *Geaster*.

**MANGABA, or MANGAVA.** A Brazilian name for the fruit of *Manconia speciosa*.

**MANGEL-WURZEL.** *Beta vulgaris nacrathica*. According to Dr. Prior, this was originally Mangold-wurzel.

### MANGIER. (Fr.) *Mangifera*.

**MANGIFERA.** A genus of tropical Asiatic trees, whose fruit is well known by the native name Mangio, whence the technical name has been framed. The genus is included among the *Anacardiaceae*, and consists of trees with alternate stalked entire leaves, and numerous small pinkish or yellowish flowers in much-branched panicles. The calyx is five-parted, and the petals and stamens five each, one or two only of the latter being fertile. The fruit is externally fleshy, and more or less fibrous, internally hard and bony.

The Mango, *M. indica*, grows abundantly in India, where numerous varieties are cultivated, as also in Brazil, the Mauritius, &c. The fruit of some varieties is esteemed as the most delicious of Indian fruits; but there are very numerous kinds, differing not only in flavour, but also in the size and shape of their fruit. Most of them have more or less of a turpentine flavour; the best varieties are most free from it, while the inferior kinds are stated to be little better in texture and flavour than a mixture of tow and turpentine. The unripe fruits are much used in India in conserves, jarts, and pickles, in which latter state they are frequently imported into this country. The ripe fruits, too, are constantly eaten, and are said in general to be wholesome, but frequently to produce boils in new-comers unaccustomed to their use. When cut with a knife, a blue stain is produced on the blade, from the presence of gallic acid in the pulp, which likewise contains gum and citric acid. The seeds are hulled and eaten in times of scarcity by the natives; they are said to possess anthelminthic properties.

*Mangifera indica*

The wood is soft and porous, of a grey colour when young, but brownish and harder in old trees; it is burnt together with sandal-wood by the Hindoos in the burning of their dead. The lark is employed medicinally to restrain discharges from the mucous membranes, and has been likewise well spoken of in the treatment of fevers in St. Domingo.

A soft reddish-brown gum-resin exudes from the bark when wounded, and is used

externally in certain skin diseases, and internally for the cure of diarrhoea and dysentery. The leaves and leaf-stalks are used by the natives as tooth-brushes and to harden the gums; the leaves are likewise employed in chest affections and derangements of the liver; while calcined and powdered, they are employed as an application to burns to dry up the discharges, and for the removal of warts. The seeds of the Mango not infrequently possess more than one embryo; and for an account of some curious deviations from the ordinary condition of a germinating seed, the reader is referred to a paper in the *Journal of the Linnean Society*, 1861. The Mango is cultivated as an object of curiosity in hothouses in this country, and has occasionally ripened its fruit.

An edible cake is prepared from the fruit of *M. gabenensis*, which is now referred to *Irvingia Barteri*. It is much used as an article of food by the natives of Sierra Leone, and contains a large quantity of fatty material. [M. T. M.]

**MANGKUDU.** The red dye root of *Morinda umbellata*.

**MANGLESIA.** A genus of some authors, but considered by Melasner, in his monograph of the *Protaceae*, to form a section of the large genus *Grevillea*. It contains about eight species, all from South-west Australia; and is distinguished chiefly by its flowers having a thickened style, much swollen on one side, and about as long and thick as the one-sided ovary, from which it is separated by a constriction; and by its terminal conical stigma. [A. S.]

**MANGLIETIA.** An Asiatic genus of *Magnoliaceae*, consisting of five species, one of which is confined to Java, the remainder being natives of tropical Asia, although *M. insignis* also extends to Java. All are handsome tall trees with large entire leaves, and showy flowers borne singly at the ends of the branches, and scarcely distinguishable from those of *Magnolia*. *M. insignis*, one of the Indian species, attains a height of fifty or sixty feet, its trunk yielding an even-grained wood of a light colour. It has thickish oblong lance-shaped smooth and shining leaves, and large sweet-smelling whitish flowers tinged with rose-colour. The Javanese species, *M. glauca*, likewise has fragrant flowers, but they are of a pale yellow colour. This also produces a light-coloured solid wood of even grain, which is very much employed by the natives for making coffins, owing to its being supposed to prevent the decay of the bodies put into them. [A. S.]

**MANGO.** The fruit of *Mangifera indica*. —, **MOUNTAIN** or **WILD.** *Clusia flava*. —, **WILD.** The fruits of some species of *Irvingia*.

**MANGOLD WURZEL.** *Beta vulgaris macrorhiza*.

**MANGOSTEEN.** A delicious Eastern fruit, produced by *Garcinia Mangostana*. —, **WILD.** *Embryopteris glutinifera*.

**MANGROVE.** *Rhizophora*: hence Lindley's name of Mangroves for the *Rhizophoraceae*. —, **BLACK** or **OLIVE.** *Avicennia tomentosa*. —, **WHITE.** *Laguncularia racemosa*. —, **ZARAGOZA.** *Conocarpus erectus*.

**MANGUAI.** *Agave mexicana*. —, **DIVINUM.** *Agave Theouellii*.

**MANGUIER DE L'INDE.** (Fr.) *Mangifera indica*.

**MANGURI.** An Indian name for *Arum indicum*.

**MANI.** *Moronebia coccinea*; also a Spanish name of the Ground Nut, *Arachis hypogaea*.

**MANICARIA.** In nearly all the genera of palms the leaves are either more or less pinnate or fan-shaped; but in the present genus, which consists of a solitary species inhabiting the tidal swamps of the Lower Amazon River, they are entire, or occasionally when old irregularly split. Individual leaves frequently measure as much as thirty feet in length, and four or five in width, having coarsely serrated edges, and transverse furrows; and being of a stiff habit they stand erect upon the summit of the stout crooked stem, which usually attains the height of fifteen or twenty feet, and is deeply ringed with the scars of fallen leaves, or covered with the remains of the fibrous sheaths of the leaf-stalks. The simply branched flower-spikes, measuring three or four feet long, hang down from among the leaves, and are enclosed in an entire brown spathe of a tough fibrous or cloth-like texture, which is ultimately torn open in an irregular manner by the expansion of the confined flower-spike. The flowers are of separate sexes, borne upon the same spike. The fruit is generally three-lobed, and covered with blunt angular tubercles of a dry corky nature.

The Indians call this palm Bussu, and its immense entire leaves are invaluable to them for thatching their huts, each leaf being for that purpose split lengthwise through the midrib, and the halves arranged so that the natural furrows act as gutters for conveying away the water. The fibrous spathe also are converted into capital bags and caps by simply cutting round them near the bottom and pulling them off entire, and afterwards stretching them open as wide as possible without tearing; or, when cut longitudinally down one side, they supply a coarse but strong kind of cloth. [A. S.]

**MANICATE.** Said of surfaces covered with hairs, so entangled that they can be stripped off like a skin.

**MANIHOT.** To this genus of *Euphorbiaceae* belongs the celebrated *Cassava* or *Manihot* plant, the fleshy root of which yields the greatest portion of the daily food of the natives of tropical America, and one of the products of which is well-known in this country under the name of Tapioca. A large number of species, all

American, are described. They are woody or shrubby plants growing from fleshy tuberous roots, their stems being without prickles or glands, their leaves generally long-stalked, palmately divided, and their flowers, which are of separate sexes, disposed in panicles in the axils of the leaves or at the ends of the branches.

Cassava or Mandioca meal is yielded by two so-called species, which, however, bear such great resemblance to each other that most botanists combine them. These are: *M. utilisima*, the Bitter Cassava, a shrubby

*Manihot utilisima*.

Plant growing from six to eight feet high or more, with erect somewhat twisted knotty stems rising from long thick fleshy cylindrical roots of a yellowish colour, containing a poisonous milky juice, and bearing deeply seven-parted leaves on very long slender stalks, crowded together at the tops of the branches; and *M. Atipi*, the Sweet Cassava, which differs principally in having sweet wholesome roots of a reddish colour, and usually only five-parted leaves; but these differences are not of specific value, and the plants must be regarded as varieties of one species. It is quite clear, however, that while the root of one is bitter and a most virulent poison, that of the other is sweet and wholesome, and is commonly eaten cooked as a vegetable. Both of them, especially the bitter, are most extensively cultivated over the greater part of tropical America, and yield an abundance of wholesome and nutritious food, the poison of the bitter kind being got rid of during the process of preparation it undergoes. This consists in first reducing the large fleshy roots to a pulp by grating them, the poisonous juice being then expelled by pressure, and the residual mass pounded into a coarse meal resembling bread-crumbs, which is made into thin cakes, or cooked in various ways, the heat dissipating any remaining poison. The

poisonous expressed juice, if allowed to settle, deposits a large quantity of starch, known as Brazilian Arrowroot or Tapioca meal, from which the tapioca of the shops is prepared by simply torrefying the moist starch upon hot plates, the heat causing the starch grains to swell and burst and become agglutinated together. A sauce called Cassareep, used for flavouring soups and other dishes, particularly the West Indian dish known as pepper-pot, is also prepared from this juice by concentrating and rendering it harmless by boiling.

Another of the products of Cassava is an intoxicating beverage called Piwarrie, but the manner of brewing it is not calculated to render it tempting to Europeans. It is made by the women, who chew Cassava cakes and throw the masticated material into a wooden bowl, where it is allowed to ferment for some days, and then boiled. It is said to have an agreeable taste. [A.S.]

MANIOO. (Fr.) *Manihot utilisima*.

MANINE. (Fr.) *Clavaria digitata*.

MANJACK. *Cordia macrophylla*.

MANISAN. A thick syrup obtained by boiling the saccharine sap of *Nipa fruticans*.

MANISURIS. A genus of grasses belonging to the tribe *Botoboeaceæ*, and containing two species, both of which are annuals, natives of the warm parts of Africa and the West Indies. [D.M.]

MANITA. *Ochetostemon platanoides*.

MANJIRIKA. An Indian name for *Ocimum Basilicum*.

MANUCHOO. An Indian name for *Arum indicum*.

MANNA. A saccharine purgative product discharged from the bark of various species of ash, chiefly *Ornus rotundifolia* and *europæa*. Similar substances are also produced by the cedar, the oak, the cistus, and by *Eucalyptus mannifera*. — of Brangançon. A turpentine saccharine exudation from the larch. — of Mount Sinai. A product of *Tamarix mannifera*. —, HEBREW or PERSIAN. A product of *Alhagi Maurorum*, or, according to others, of *Tamarix mannifera*: see GEN. —, POLAND. *Glyceria fuitana*.

MANNA CROUP. The prepared seeds of *Glyceria fuitana*.

MANNE DE PRUSSE. (Fr.) *Glyceria fuitana*.

MANONIM. A name in Minnesota for *Zizania aquatica*, or Wild Rice.

MANSIENNE. (Fr.) *Viburnum Lantana*.

MANSOA. A genus of *Rignonaceæ*, named in honour of A. P. da Silva Manso, a Brazilian botanist, and consisting of only two species, both of which are climbing shrubs with conjugate leaves furnished with tendrils, and handsome white or violet flowers arranged in panicles, having a bilabiate calyx, the segments of which are divided into five long lobes, a funnel-shaped

corolla, and four stamens, with the rudiment of a fifth. The fruit and uses of these plants, both natives of Brazil, are unknown. [R.S.]

**MANTELET DES DAMES.** (Fr.) *Alchémilla*.

**MANTISIA.** A genus of *Zingiberaceae*, deriving its name from the resemblance of the flowers to the insect *Mantis*. It is nearly allied to *Glozza*, but is distinguished from it by the lateral inner segments of the corolla being narrow and linear, and adherent to the filament of the stamen above the labellum; the anther, moreover, is dilated on each side into a membranous wing. One of the species has long been grown in hothouses in this country, from the singularity and beauty of its flowers, which

*Mantisia saltatoria*.

present some resemblance to a ballet-dancer; hence the popular name, Dancing Girls, applied to the plant. The filament and anther with its wing-like margins, represent the head and neck of the lady, the long inner segments of the corolla represent the arms, while the labellum corresponds to the dress. The flowers are purple and yellow. The name, *Mantisia saltatoria*, expresses the resemblance both to an insect and to a dancer. [M. T. M.]

**MANULEA.** A genus of *Scrophulariaceae*, of the tribe *Gratiolae*, distinguished by a five-cleft calyx with narrow lobes; by a corolla with a slender straight tube, and a spreading limb nearly equally divided into five lobes which are often notched or cleft; and by didynamous stamens enclosed in the tube, with one-celled anthers. There are nearly thirty species, natives of Southern Africa, all herbs or rarely low undershrubs, with the leaves usually radical on the lower part of the stem only. The flowers are terminal in racemes, or more frequently clustered in narrow irregularly compound panicles. They are usually yellow, orange, or red, small, but sometimes very numerous.

**MANYROOT.** A West Indian name for the emetic *Ruellia tuberosa*.

**MAOOSA.** The fibre of a species of *Urtica* used in Ceylon.

**MAPLE.** *Acer*. —, **BIRD'S-EYE.** *Acer saccharum*. —, **ITALIAN.** *Acer Opulus*. —, **NORWAY.** *Acer platanoides*. —, **RUGEL.** *Acer saccharinum*. —, **SWAMP.** *Acer rubrum*.

**MAPPA.** A genus of *Euphorbiaceae*, of the tribe *Aculphree*, now referred to *Macaranga*, consisting of trees with large usually peltate leaves, and small flowers in axillary or lateral panicles. The calyx is small, without petals; the male flowers in clusters with three to ten stamens bearing small globular four-lobed anthers; the females solitary, usually with a two-celled ovary, growing into a capsule usually bearing soft prickles or subulate processes. There are several species in the tropical regions of Asia and Eastern Africa. Among them *M. Tannaria* is said to yield a good tan in the Indian Archipelago.

**MAPROUNEA.** A genus of *Euphorbiaceae*, of the tribe *Cratoneae*, consisting of trees with small glabrous alternate ovate entire leaves, and small flowers, the males growing in little oval cone-like heads, at the base of which are some long-stalked female ones. There are only three species known, all from tropical America.

**MAQUI.** (Fr.) *Aristotelia*.

**MARA.** A Guiana wood furnished by *Icica altissima*.

**MARACAUBA.** A Brazilian furniture wood, intermediate in appearance between mahogany and tulip-wood.

**MARAM or MARRAM.** *Amnophila arenaria*.

**MARANTACEÆ.** (*Cannaceæ*.) A natural order of epigynous monocotyledons, belonging to Lindley's annual alliance of Endogens. Herbaceous plants, with tuberous rhizomes, and leaves and flowers similar to those of the ginger family. Perianth superior, in two whorls: the outer (calyx) three-lobed short, the inner (corolla) tubular elongated three-parted, the segments nearly equal; stamens in two whorls: the outer sterile petaloid irregular, resembling a tubular tri-lobed corolla with one of the lateral segments different, the inner petaloid, two being sterile, and one lateral fertile, the filament of the latter petaloid; anther on the margin of the filament, one-celled; ovary three-celled, rarely one-celled, the ovules solitary and erect, or numerous and attached to the axis; style petaloid; stigma either the naked apex of the style, or hollow hooded and incurved. Fruit a three-celled capsule, or baccate one-celled and one-seeded; seeds round, without arillus; embryo straight, in hard albumen. They are natives of tropical America and Africa; several are found in India; none are known in a wild state beyond the tropics. The plants contain much starch in the rhizomes and

but are destitute of arbus. Arrow-root is the produce of the tuberous rhizomes of *Maranta*; while *Canna coccinea*,

*C. Achiras*, *C. edulis*, &c., yield *Tous-les-mois*. There are nine genera, including *Canna*, *Maranta*, and *Phrynium*, and upwards of 150 species. [J. H. D.]

**MARANTA.** Maranti, after whom this genus was named, was a Venetian botanist and physician of the middle of the sixteenth century. The genus, which gives its name to the *Marantaceæ*, consists of herbaceous plants with fleshy tubers, and terminal panicle jointed inflorescence with deciduous scale-like bracts. The flowers have a calyx of three sepals; a corolla of six segments, the central one or lip of the inner series larger than the lateral ones, and cleft; a petaloid stamen with half an anther on one side of it, and a hooded style adhering to a barren petal-like filament.

The species are natives of tropical America, but are cultivated for the sake of the starch in their tubers in both East and West Indies, Sierra Leone, &c. *M. Allouya*, *M. nobilis*, and especially *M. arundinacea*, are cultivated in the West Indies, and, in addition to the above-named species, *M. ramosissima* is cultivated for like purposes in the East Indies. The term Arrow-root is said to be derived from the fact that the native Indians used the roots of these plants as an application to wounds inflicted by poisoned arrows. The tubers whence the Arrow-root is procured are whitish, jointed, and horizontal, and give origin to numerous off-shoots, that are covered with rudimentary leaves or scales; these ultimately appear above ground and throw up new stems. The starch is extracted from the tubers, when these are ten or twelve months old, by reducing them to a pulp with water, straining, allowing the fecula to subside, again washing it, and ultimately allowing it to dry.

Arrow-root is a very pure kind of starch, and is very nutritious. It is frequently adulterated with other cheaper starches, which fact may readily be detected by the microscope. Other descriptions of Arrow-root are furnished by plants belonging to the following genera: *Arion*, *Canna*, *Curcuma*, *Jatropha*, *Tacca*—to which articles the reader is referred for further information. Mats used for shading in India are frequently made of the split stems of *M. dichotoma*. [T. M.]

**MARASCHINO.** A liqueur prepared from the Cherry.

**MARASMIUS.** A genus separated from *Agaricus* on account of the leathery texture of the species, which revive on the application of water, and other less obvious characters. Two distinct sections occur, in the first of which the spawn is floccose, and in the second resembles fibrous roots. The former group contains the more fleshy species, of which *M. Orades* or Champignon is one of our very best esculent fungi, while *M. scorodonthus* is an excellent condiment. The latter comprises a multitude of thin often splendidly coloured fungi, which abound in tropical countries, and vie with each other in elegance. *M. hæmatocephalus*

has occurred in one of the stoves at Kew, and if some of the more showy species could be cultivated successfully, it would be difficult to conceive anything more attractive. Some of our own species, though more modest in point of colouring, are delightful objects; and the little *M. Hudsoni*, with its long tawny bristles radiating in every direction from the pilius, which is common on holly leaves, is a plant of surprising beauty when closely examined. [M. J. B.]

**MARATTIACEÆ. MARATTIA.** An order and genus of ferns, separated on the one hand from *Polypodiaceæ* by the absence of a jointed ring to the spore-case; and on the other from *Ophioglossaceæ*, which agree

*Marattia fraxinea.*

in having ringless spore-cases, by having the sori dorsal, and the venation circinate. The order includes the genera *Marattia*, *Gymnotheca*, *Eupodium*, and *Angiopteris*, which have distinct oblong sori consisting of free or concrete longitudinally bivalved spore-cases; *Kaulfussia*, which has distinct circular sori made up of an annular series of concrete spore-cases; and *Danaea*, in which the sori are connate over the whole dorsal surface of the fronds.

*Marattia* differs from the other genera of the order in having oblong sessile sori made up of concrete spore-cases, and seated on a fimbriate persistent involucre. It consists of a few coarse-habited plants, with large globose scaly rhizomes, and ample twice or thrice pinnate fronds, with fleshy stipules, and large oblong lance-shaped pinnules, bearing the sori in lines near their margins. They occur in South America, the Eastern and Pacific Islands, in South Africa, the Mascaren Islands, and the Island of Ascension. [T. M.]

**MARO.** The cake or refuse after expressing the oil or juice from fruits or seeds, as of apples, olives, grapes, &c.; it is mostly used for manure.

**MARCASSON.** (Fr.) *Lathyrus tuberosus*.

**MARCEAU.** (Fr.) *Salix Cuprea*. —, PETIT. *Salix aurita*.

**MARCELLA.** A Brazilian name for *Grangea maderaspatana*.

**MARCESCENT, MARCID.** Not falling

off until the part which bears it is perfected, but withering long before that time, as the flowers of *Orobanchæ*.

**MARCEA.** Little rigid mostly hairy undershrubs, generally with small heath-like leaves, and small white or reddish flowers in the upper leaf-axils. The genus belongs to *Melastomaceæ*, and numbers about a dozen species, all Brazilian. It has tetramerous flowers, with a campanulate subulate-toothed calyx; mostly acuminate petals; eight stamens with subulate somewhat curved anthers opening by a single pore, and the connective scarcely prolonged at the base; and a four or rarely three-lobed ovary bearing a filiform style and punctiform stigma. [A. S.]

**MARGRAVIA.** (*Muregraviæ*.) A natural family of dicotyledons belonging to Lindley's Rutifloral alliance of hypogynous Euxoëns. Trees or shrubs, with alternate entire simple leathery and exstipulate leaves. Flowers often furnished with pitcher-like bracts; sepals two to seven, coriaceous and persistent; corolla hypogynous of five petals, or gamopetalous calyptriform; stamens usually indefinite, very rarely five, hypogynous, the filaments dilated at the base, the anthers long, erect, introrse; ovary single, one-celled; style one; stigma often capitate. Fruit coriaceous, indehiscent, or dehiscent by valves in a loculicidal manner, the placentas being parietal and forming spurious dissepiments; seeds indefinite, minute. They occur chiefly in the warmer parts of America. There are four genera, and about two dozen species. Examples: *Margravia*, *Norantea*. [J. H. B.]

**MARGRAVIA.** One of the few genera of *Murgraviaceæ*, an order now reduced by some botanists to a section of *Ternstroemiaceæ*. There are but few species, all belonging to tropical America, and all large climbing or almost epiphytall shrubs, with thick leathery quite entire leaves on short stalks, and long-stalked flowers in terminal umbels or corymbiform racemes. It is distinguished from its allies by its petals being united into a cap-like corolla, which becomes detached round its base and falls off in a single piece; also by its stamens being indefinite, or never less than twelve; and by its incompletely four to twelve-celled ovary. In the West Indies, *M. umbellata* was formerly considered to possess medicinal properties. [A. S.]

**MARCH.** An old name of Parsley.

**MARCHANTIA.** An important section of liverworts, distinguished from other members by very striking characters. The frond is never leafy, frequently forked, with the surface divided into little areas and porous. The male fruit is immersed in sessile or stalked discoid or peltate receptacles. The capsules are disposed symmetrically on the under side of stalked wheel-shaped receptacles, and are either valvate or bursting irregularly, or very rarely solitary and sessile, or merely

grouped together. The stalk is often sheathed; and the spores are mixed with elaters. They are divided into three natural orders:—

1. **TARGONIEÆ:** with single sessile capsules, sometimes grouped together.
2. **JECORARIEÆ:** with capsules on the under side of a common stalked receptacle.
3. **LUNULARIEÆ:** with capsules on a common peduncle.

They grow in moist places, spreading over the ground, stones, &c., and attached by delicate rooting fibres. Besides the regular fruit, there are often separate organs which contain gemmæ, by means of which the plants are multiplied. The archegones are produced on the frond itself, and give rise to the fruit, not to a new plant, and the spermatozoids are like those of *Chara*, but have fewer volutions in the spiral, which is in many cases at length completely expanded. *Marchantia polymorpha*, which occurs everywhere on shady walks and on the soil of garden-pots, is the most familiar example, and will amply reward a close inspection. It is a popular remedy, along with some other allied species, for jaundice and consumption, but its virtues are in all probability imaginary. [M. J. B.]

**MARCKEA.** A genus named in honour of the famous French naturalist Lamarck, and belonging to the order *Atropnceæ*. The species is a climbing shrub, native of Guiana, with axillary clusters of scarlet flowers, having a tubular calyx; a funnel-shaped corolla, divided into five obtuse segments; five stamens, concealed within the tube of the corolla, to which they are adherent, the anthers opening longitudinally; and a two-celled ovary with numerous ovules in each compartment, and a simple style. Fruit capsular, two-valved, many-seeded. [M. T. M.]

**MAREBLOBS.** *Caltha palustris*.

**MARE'S-TAIL.** *Hippuris*.

**MARGINAL.** Belonging to the margin or edge of anything.

**MARGINARIA.** *Goniophlebium*.

**MARGINATE.** Furnished with an edge of a different texture from the remainder of the body.

**MARGOSA-TREE.** *Melia Azadirachta*.

**MARGOTIA.** A genus of campylospermous *Umbellifera*, characterised by the inner face of the seed being furrowed instead of flat. Its nearest ally is *Elaeoselinum*, from which it differs in the white deeply bilobed petals with long incurved tongue-like apices. The only known species, *M. laserptioides*, found in Spain, Portugal, and North Africa, is a smooth perennial herb with a tall erect naked stem, bearing many-rayed umbels of small white flowers which, as well as the leaves, are like those of the carrot. The carpels have the five primary ribs obsolete, and the four secondary produced into thin wings, the outer two of which are the broadest. They secrete an abundance of aromatic oil, which

also occurs in the form of tears on the rays of the umbels. [A. A. B.]

**MARGOUSIER.** (Fr.) *Melia scarperviora*.

**MARGUERITE.** (Fr.) *Delila perennis*. — **BÂTARDE.** *Silphium*. — **BLRUE.** *Globularia*. — **DE LA ST. MICHEL.** *Anter Amellus*. — **DORRÉ.** *Chrysanthemum argatum*. — **GRANDE.** *Chrysanthemum Leucanthemum*. — **PETITE.** *Helix annua*. — **REINE.** *Callistephus chinensis*.

**MARGYRICARPUS.** A much-branched prostrate undershrub, with small plinnate linear-subulate leaves, and small insignificant flowers sessile in their axils, forming a genus of *Rosaceæ*, allied to *Acæna*, but without any hooked bristles on the calyx, and the fruit consisting of a small drupe. It is common on arid hills in Chili and Peru.

**MARI.** A Brazilian name for the fruits of *Geoffroya superba*.

**MARIANTHUS.** A small genus of Western Australian *Pittosporaceæ*, consisting of climbing shrubs. One species, *M. caudatus*, has alternate elliptical attenuate leaves, with revolute margins, and white flowers in terminal heads. These latter have a small five-parted calyx, five spatulate petals slightly coloring at the base, five stamens with ovate anthers, a slightly curved filiform style, and a two-celled ovary containing numerous seeds. *M. ceruleopunctatus* has pretty pale blue spotted flowers, and is sometimes cultivated. [L. H.]

**MARICA.** This name was first improperly substituted by Schreber for *Anulet's* name *Oipura*, given to an Iridaceous plant found in Gulana; and was afterwards applied by Ker to a closely allied plant of the same order, which now constitutes the type of a small genus. All the species belong to tropical America, and are herbaceous plants with short rhizomes, flat leaves placed edgewise, and a flat winged flower-stalk ending in a leaf-like spathe. Their perianth has three large spreading outer and three smaller inner segments; the stamens are distinct; the style slender below and triangularly enlarged upwards into three lobes, each with three sharp rigid crests; and the stigma is short and transverse like that of *Iris*. [A. S.]

**MARICHU.** A Sanscrit name for Pepper.

**MARIET.** *Campanula urticifolia*.

**MARIETTE.** (Fr.) *Campanula Medium*.

**MARIGOLD.** *Calendula officinalis*. — **AFRICAN.** *Tagetes erecta*. — **BURL.** *Bidens tripartita*. — **CORN.** *Chrysanthemum segetum*. — **FIG.** *Mesembryanthemum*. — **FRENOH.** *Tagetes patula*. — of the West Indies. *Pectis punicata*. — **MARSH.** *Caltha*. — **POT.** *Calendula officinalis*; also *Mesembryanthemum calendulaceum*. — **WATER.** *Bidens Beckii*. — **WEST INDIAN.** *Wedelia carnea*.

**MARILA.** A genus of *Ternströmaceæ*,

differing from almost all others in its opposite leaves, and on that account placed by some in *Clusiaceæ*, and by others in *Hypericaceæ*, but the inflorescence and flowers are much more those of *Ternströmaceæ*. There are four species, South American or West Indian trees, the evergreen leaves elegantly marked with transverse veins between the principal ones. The flowers are in axillary racemes, with four or five sepals and petals, numerous stamens, and an oblong ovary of four or five cells. The capsule contains numerous seeds, with fringed wings at each end.

**MARINE SAUCE.** A name sometimes given to the common Laver, *Porphyra vulgaris*.

**MARISCUS.** A genus of cyperaceous plants belonging to the tribe *Cyperæ*. The spikes of inflorescence are one to two-flowered, rarely three to five-flowered; scales two-rowed, imbricated; stamens three; styles three-cleft; nuts triangular. This extensive genus contains nearly a hundred species, the greater part of which are tropical, or bordering on the tropics. [D. M.]

**MARJOLAINE.** (Fr.) *Origanum Majorana*. — **À COQUILLE.** *Origanum necosum*.

**MARJOLIN.** An early variety of Potato.

**MARJORAM.** *Origanum*. — **KNOTTED.** *Origanum Majorana*. — **POT.** *Origanum Onites*. — **SWEET.** *Origanum Majorana*. — **WINTER SWEET.** *Origanum heracleoticum*.

**MARKING FRUIT.** *Scemecarpus Anacardium*.

**MARMALADE-TREE.** *Lucuma mammosum*.

**MARMALADE-BOX.** *Genipa americana*.

**MARMALA-WATER.** A fragrant liquid distilled in Ceylon from the flowers of the Bengal Quince, *Egle Marmelos*.

**MARMALEIRO DO MATO.** *Cassarea ulmifolia*. — **DO CAMPO.** *Mayrounea brasiliensis*.

**MARMELOS.** *Egle Marmelos*.

**MARMORATE.** Marbled; traversed by irregular veins of colour, as a block of marble often is.

**MAROO.** The long fine fibre of *Sansiviera zeylantica*.

**MAROUCHIN.** (Fr.) An inferior sort of Wood.

**MAROUTE.** (Fr.) *Anthemis Cotula*.

**MARRAM, or MARRUM.** *Ammophila arenaria*.

**MARROCHEMIN.** *Marrubium vulgare*.

**MARRON.** (Fr.) The fruit of *Castanea vesca*. — **D'EAU.** *Trapa natans*.

**MARRONETO.** An Italian name for an orchard of chestnut trees.

MARRONNIER D'INDE COMMUN. (Fr.)  
*Euclea Hippocastanum*.

MARROW, VEGETABLE. *Cucurbita ovifera*.

MARRUBE. (Fr.) *Marrubium vulgare*.  
— AQUATIQUE. *Lycopus europæus*.  
— BLANC. *Marrubium vulgare*. — NOIR.  
*Ballota nigra*.

MARRUBIUM. This name is said to be derived from the Hebrew word Marrob, signifying a bitter juice, and is applied to a genus of *Labiata*, of which the White Horehound is the most familiar example. The genus comprises several herbaceous species, natives of Southern Europe and Western Asia. The calyx is five to ten-nerved, and has an equal number of teeth; the corolla has the upper lip flat, entire or slightly notched, and the lower three-cleft; the stamens are concealed within the tube of the corolla; and the style is cleft.

*M. vulgare*, the Common or White Horehound, has an erect branched stem densely covered with cottony white hair; the leaves are roundish, crenated wrinkled and soft; the flowers whitish, crowded in the axils of the leaves. This plant is occasionally met with in a wild state in this country, and is widely distributed throughout Europe and Northern Asia, and has moreover become naturalised in America. It has bitter tonic properties, and was once employed in many diseases, but has fallen into disuse except as a domestic remedy in chest complaints. [M. T. M.]

MARSDENIA. A large genus of *Asclepiadaceæ*, spread over the East Indies, Moluccas, New Holland, and tropical America. Only one species, *M. erecta*, inhabits the south-eastern parts of Europe. There are about thirty species, either erect shrubs or twiners, with opposite leaves, and interpetiolar bunches of whitish or greenish flowers. The calyx is five-cleft, the corolla bell-shaped, rotate or urn-shaped, and the fruit quite smooth. *M. tenacissima* yields a fibre which is employed for bowstrings by the mountaineers of Rajmahal. The leaves of *M. tinctoria* and *parviflora* yield by decoction a blue dye resembling indigo. The leaves of *M. erecta* were formerly used by chemists under the name of *Herba Apocyni folio subrotundo*, and are still sometimes employed. The milky juice of the plant raises blisters on the skin, and taken internally it causes violent trembling and convulsions, and ultimately death. [B. S.]

MARSHALLIA. A genus of *Compositæ* of the tribe *Helianthæ*, consisting of four North American species, perennial herbs, with alternate entire and glabrous three-nerved leaves, and solitary flower-heads of 4 pale purple or rose colour, resembling those of a scabious. The involucreal scales are linear-lanceolate, leaflike, in one or two rows, the receptacle convex or conical and chaffy; the florets are all tubular, and the achenes hairy, with a pappus of five or six ovate or lanceolate scales.

MARSH-BEETLE, or MARSH-PESTLE.  
*Typha latifolia*.

MARSH-FLOWER. *Immananthemum*.  
MARSHWORT. *Oxyccoccus palustris*.

MARSILEACEÆ. A natural order of pseudoferns, consisting of two distinct groups, to the first of which belong *Marsilea* and *Pilularia*, to the second *Azolla* and *Salvinia*. The vegetation is either straight or circinate, formed of a metamorphosed leaf; the receptacles one or many-celled; the antheridia in the same secondary receptacle with the mostly monosporous sporangia, or in a distinct sac; and the prothallus confluent with the spore itself. All the genera are aquatic, though, after the water is dried up, some of the species are still capable of maintaining life. *Azolla* is extra-European; the three other genera occur in Europe, but have representatives in other parts of the world. The fossil *Sphenophyllum* probably belonged to the same natural order. [M. J. B.]

MARSILEA. A genus of pseudoferns, with a creeping rhizome and erect leaves consisting of a long stalk and two pairs of leaflets, which are circinate when young, disposed in a cross, nerved somewhat after the fashion of those of *Adiantum*, and which at night fold up like the leaflets of many *Leguminosæ*. The fruit consists of hard thick receptacles, divided into several cells arranged on the two sides of the principal septum parallel to the flattened surfaces of the receptacle. Each of these contains two kinds of organs, fixed to a sort of placenta, those at the base containing a single spore, those above granules which at length yield spermatozooids like the small spores of *Salvinella*. The receptacles sometimes spring from the rhizome, but are sometimes attached to the base of the petioles. Species occur in temperate and hot climates, as the South of Europe, Africa, Oregon, Madras, Australia, Brazil, &c. *M. macropus* is the Nardoo of Australia. [M. J. B.]

MARSYLIANTHES. A genus of *Labiata*, distinguished by its bell-shaped calyx having five equal erect teeth; by the upper lip of the corolla being bifid, the lower three-lobed, the lateral lobes nearly equal in size and ovate, the middle concave with an acute point; and by each piece of the fruit being concave on the inner surface, the border fringed. *M. hyptoides* of tropical America, the only species, is a procumbent annual with heads of blue-purple flowers. [G. D.]

MARTINEZIA. A genus of tropical American palms consisting of six species, all of them small trees with cylindrical trunks seldom more than twenty or thirty feet high, and often armed with spines, as also are the leaf-stalks. The leaves are pinnate, with the segments of a wedge-shaped or three-sided form, the broad upper end being very much jagged or torn. The simply-branched flower-spikes are enclosed in a double spathe, the outer of which is incomplete, the spathe and the

lower part of the spike being frequently covered with black spines; both sexes of flowers have a three-parted or three-sepaled calyx, and a three-petaled corolla. The fruits are globular and fleshy, and contain a hard smooth pitted stone. [A. S.]

**MARTYNA.** A genus of *Pedaliaceæ*, mostly confined to Mexico. It consists of branching herbaceous plants covered with clammy hairs, and having roundish somewhat heart-shaped leaves, and spikes of flowers of which the calyx is divided into five nearly equal pieces, and the irregular bell-shaped corolla is unequally five-lobed and puffed out below. The fruit is a hard woody wrinkled capsule terminating in two curved beaks or hooks, and is divided into four cells containing several large seeds. *M. fragrans* is an annual, two or three feet high, occasionally seen in our gardens, where it thrives in the open air during the summer months, producing spikes of large rich purplish-red flowers streaked with yellow, and exhaling a most delicious odour. Its singular fruits are prolonged upwards into two curved sharp hooked horns three or four inches long, which cause great annoyance to travellers in Mexico by catching hold of their clothes. Another species, *M. proboscidea*, is called *Testa di Quaglia* by the Italians; while the Mexicans give the name of *Unguis Diaboli* to the short hooked fruit of *M. triloba*. [A. S.]

**MARUM.** (Fr.) *Teucrium Marum*.

**MARUTA.** A genus proposed by Cassini, and adopted by De Candolle, for the *Anthemis Cotula*, and one or two other species, which have the ray florets neuter and barren. *M. Cotula* is a common cornfield weed with a very disagreeable smell, closely resembling in all other respects several other species of *Anthemis*, with which genus many botanists reunite it.

**MARVEL OF PERU.** *Mirabilis*.

**MARY-BUD.** *Calendula officinalis*.

**MARY'S FLOWER.** *Anastatica Hieracantha*; also *Marianthus*.

**MARZUOTO.** A kind of spring corn grown in Tuscany, the straw of which is used for plaiting.

**MASCULAR, MASCULINE.** Whatever belongs to the stamens.

**MASDEVALLIA.** A considerable genus of South American orchids, of the tribe *Malaceæ*, consisting of little epiphytes, with creeping rootstocks, and broad leaves narrowed downwards into stalks. It is well distinguished by its flowers, which are borne singly on radical stalks, having the sepals joined into a tube, except at their apices, where they are free and drawn out into long narrow tails. The petals are free, very small, and concealed in the tube of the sepals, as also is the lip, which is sessile and articulated with the incurved half-rounded column. They are very remarkable for the singularity of their flowers, and also for their beauty. [A. S.]

**MASER-TREE.** *Acer campestre*.

**MASH.** An Indian name for *Phaseolus radiatus*, a kind of pulse.

**MASKED.** The same as *Personate*. A body is also said to be masked when its true nature is concealed or disguised.

**MASK-FLOWER.** *Alonsoa*.

**MASSE AU RÉDEAU.** (Fr.) *Dunias Erucago*. — **DÉAU.** *Typha latifolia*.

**MASSES.** Collections of anything in unusual quantity; as, for example, pollen-masses, which are unusual collections of pollen.

**MASSETTE.** (Fr.) *Typha*.

**MASSONIA.** A genus of Cape bulbs, belonging to the *Liliaceæ*. The leaves are commonly two in number, and lie flat on the ground; and the flowers are in an umbel-like head nearly sessile between the leaves and surrounded by a many-leaved scarious involucre. The perianth is salver-shaped, usually white, with a six-parted spreading or reflexed limb. These plants have but little beauty, but their appearance is very singular. [J. T. S.]

**MASTACANTHUS.** A genus established by Endlicher to receive a verbenaceous plant which has been since referred to *Caryopteris*. [W. C.]

**MASTER-WORT.** *Imperatoria*; also *Astrantia*. —, **ENGLISH.** *Ænopodium*. —, **GREAT.** *Imperatoria Ostruthium*.

**MASTIC DES INDES.** (Fr.) *Schinus*. — **DE SYRIE.** *Teucrium Marum*.

**MASTICH.** The resiniferous *Pistacia Lentiscus*. —, **BARBARY.** *Pistacia atlantica*. —, **WEST INDIAN.** *Bursera gumifera*. —, **PERUVIAN.** *Schinus Molle*.

**MASTWOOD, YELLOW.** *Tobinia coriacea*.

**MASTWORTS.** Lindley's name for the *Corylaceæ*.

**MASUR.** An Indian name for *Eryum Lens*.

**MATAR.** An Indian name for Peas.

**MATAYBA.** A Guiana tree described as a genus of *Sapindaceæ*, as yet imperfectly known, but supposed to be a species of *Cupania*.

**MATÉ.** A South American name for *Ilex paraguayensis*.

**MATFELLON.** *Centaurea nigra*.

**MATHEE.** An Indian name for *Trigonella fœnum græcum*.

**MATHER.** *Anthemis* or *Maruta Cotula*.

**MATHEWSIA.** A genus of *Cruciferae*, forming a branched Chilean shrub, having somewhat fasciculate linear-lanceolate pin-natifid leaves clothed with fine stellate hairs, and bearing elongated terminal racemes of rather large flowers. The pouch is two-valved, elliptical or lanceolate, sur-

mounted by the sessile stigma, compressed, parallel to the partition, with flat reticulate one-nerved valves. [J.T.S.]

**MATICO.** A drug obtained from *Artanthe elongata* and *adunca*; also from *Eupatorium glutinosum*, and *Walteria glomerata*; and, according to Martius, from a species of *Phomia*.

**MATONIA pectinata** is the only species of a genus of *Polypodiaceæ*, distinct in aspect and character from all other known ferns. From a creeping rhizome rises a tall slender erect ebony stalk, on the top of which is a conjugate fan-shaped frond, each half a counterpart of the other, and consisting of several long rigid linear pinnatifid branches. The fronds have something the aspect of the *Mertensia* group of *Gleichenia*, but the suboblique ring of the spore-case indicates relationship with the *Cyatheaceæ*, in the neighbourhood of which it is now classed as a distinct tribe, the *Matonineæ*. The sori are globose on compital receptacles, and covered by umbonate-hemispherical indusia with a central stalk, and incurved margins. The veins are free, except where they anastomose to form the receptacles. [T.M.]

**MATRICAIRE**, or **M. COMMUNE**. (Fr.) *Pyrethrum Parthenium*. — **MANDIANE**. *Anthemis parthenioides*.

**MATRICARIA.** A genus of herbaceous plants belonging to the tribe *Corymbifera* of compound flowers, of which the characters are: fruit angular, crowned with a large disk; pappus, when present, a membranaceous border; receptacle naked; florets of two colours. The genus is represented by the Corn Mayweed, *M. inodora*, and the Wild Chamomile, *M. Chamomilla*, common weeds with daisy-like flowers, and deeply cut capillary leaves, the latter with a slightly bitter taste, and a smell approaching that of the true Chamomile. French, *Matricaire*; Germ. *Mutterkraut*. [C. A. J.]

**MATRIMONY-VINE.** *Lycium barbarum*.

**MATTHIOLA.** A genus of cruciferous plants, of which the characteristic features are: siliques nearly cylindrical; stigmas connivent, thickened or horned on the back; seeds thin and flat, one-rowed, numerous. Two species are indigenous to Britain: *M. incana*, which grows on cliffs in the Isle of Wight, and is the origin of all the garden varieties of Brompton Stock; and *M. sinuata*, the Great Sea Stock, an herbaceous plant with rugged pods, rare on the shores of Cornwall and Wales. *M. tristis*, a humble plant with narrow hoary leaves and dingy brown flowers, a native of the south of Europe, is best known as the Night-scented Stock. *M. annua* is the original of all the varieties of Ten-week Stock, and *M. græca* of the smooth-leaved annual Stocks. French, *Glofinche*. [C. A. J.]

**MATTIA.** A genus of *Doraginaceæ*, found in South-eastern Europe and Asia Minor, consisting of white pubescent herbs, with

linear-oblong leaves, and umbellate-corymbose blue or yellow flowers. [J.T.S.]

**MATUTINAL.** Happening early in the morning.

**MATWEED.** *Ammophila arenaria*, also called Sea Matweed. —, **HOODED.** *Lygum Spartum*. —, **SMALL.** *Nardus stricta*.

**MAUDLIN, SWEET.** *Achillea Ageratum*.

**MAUDLINWORT.** *Chrysanthemum Leucanthemum*.

**MAULE.** *Malva sylvestris*.

**MAURANDIA.** A genus of *Scrophulariaceæ*, nearly allied to *Antirrhinum*, and like that genus comprising annuals and perennials, either erect, or more frequently climbing and supporting themselves by their twisted peduncles and petioles. They differ from *Antirrhinum* in the tube of the corolla not being swollen into a pouch at the base, in the less prominent palate at the mouth of the tube, and in the capsule, of which each cell opens in several valve-like teeth. Three handsome climbing species, *M. antirrhiniflora*, *M. semperflorens*, and *M. Barclayana*, all natives of Mexico, with cordate or hastate leaves and showy flowers, are frequently cultivated in our gardens. The two remaining erect species are Californian.

**MAURITIA.** A genus of palms peculiar to tropical South America. They grow to an immense size, some species attaining the height of a hundred or a hundred and fifty feet, and bearing a crown of enormous fan-shaped leaves, from amongst which the pendulous flower-spikes are produced. These spikes, which are often very large and much branched, bear the flowers in numerous catkins, which, as well as the branches, have their bases sheathed in incomplete tubular spathe. The different sexes are on distinct trees, but they are intermingled with perfect flowers. The fruits are covered with hard shiny scales, which give them a tessellated appearance. *M. flexuosa*, the Moriche or Ita Palm, is very abundant on the banks of the Amazon, Rio Negro, and Orinoco rivers. In the delta of the latter it occupies swampy tracts of ground, which are at times completely inundated, and present the appearance of forests rising out of the water. These swamps are likewise frequented by an independent tribe of Indians, called 'Guaranés,' who subsist almost entirely upon the produce of the Moriche Palm, and during the period of the inundations suspend their dwellings from the tops of its tall stems. Various parts are applied to useful purposes. The outer skin of the young leaves is made into string and cord for the manufacture of hammocks. The fermented sap yields palm-wine, and another beverage is prepared from the young fruits, while the soft inner part of the stem yields a farinaceous substance like sago. [A.S.]

**MAURITIUS-WEED.** *Roccella fuciformis*.

**MAUVE**. (Fr.) *Malva sylvestris*. — **BÂTARDE**, *Malope*. — **EN ARBRE**, *Lavatera*. — **DES INDES**, *Sida*. — **FLEURIE**, *Lavatera trimestris*. — **GRANDE**, *Malva sylvestris*. — **PETITE**, *Malva rotundifolia*.

**MAUVISQUE**. (Fr.) *Malvaviscus*.

**MAWSEED**, *Papaver somniferum*.

**MAXILLARIA**. Formerly this genus comprised a heterogeneous mass of orchids which are now separated into some half-dozen or more genera. It is now restricted to those possessing the following characters:—Flowers more or less ringent; lateral sepals adhering to the column at their oblique base; lip hooded, jointed with the prolonged claw-like foot of the column, which is narrow, ascending; pollen-masses four, incumbent, or the two hind ones adhering to the two front ones; caudicle short, attached to a semicircular gland. [A. S.]

**MAXIMILIANA**. The celebrated Humboldt, in his *Aspects of Nature*, speaks in glowing terms of the great beauty of the *Jagua*, an undetermined species of the present genus of palms, of which three or four are known, natives of the forests of Northern Brazil and the West Indies. All these are tall-growing trees, with slender smooth trunks, bearing at the summit gigantic pinnate leaves, having the narrow leaflets arranged in clusters along the leaf-stalks. The flower-spikes are each completely enclosed in a thick woody spathe, which tapers to a long point, is marked outside with deep longitudinal furrows, and eventually splits open down one side. The flowers are of separate sexes, either mixed together on the same or on distinct spikes.

*M. regia*, the Inajá Palm of the Amazon, has a trunk a hundred or more feet high, crowned with leaves from thirty to fifty feet long, and its woody spathes when open frequently measure as much as five or six feet in length by about two feet in breadth, tapering to a long point or beak. These spathes are so hard that when filled with water they will stand the fire, and are sometimes used by the Indians as cooking utensils, but more frequently as baskets for carrying mandioca flour, &c. The Indians who prepare the kind of India-rubber called bottle-rubber, make use of the hard stones of the fruit as fuel for smoking and drying the successive layers of milky juice as it is applied to the mould upon which the bottles are formed. The outer husk, also, yields a kind of saline sour used for seasoning their food. [A. S.]

**MAY**. A popular name for the flowers of *Cratægus Oxyacantha*. — **ITALIAN**, *Spirea Filipendula*.

**MAY-BUSH**, *Cratægus Oxyacantha*.

**MAYACEÆ**, **MAYACA**. A natural order and solitary genus of hypogynous monocotyledons, belonging to the xyridal alliance, comprising three or four little moss-like

marsh or semi-aquatic plants allied to *Xyridaceæ* and *Commelinaceæ*, but well distinguished by their one-celled anthers. Their inconspicuous little white, pink, or violet flowers have three sepals alternate with the carpels, three distinct petals, three stamens inserted into the base of the sepals, and three carpels combined into a one-celled pistil, which has a thread-like style and simple stigma. The species are all American, extending on the one hand to Virginia, and on the other to Brazil. Physiologically they are remarkable for their deficiency of spiral vessels. [A. S.]

**MAYDEWEED**, *Pyrethrum Parthenium*. — **RED**, *Adonis autumnalis*.

**MAY-DUKE**. A kind of cherry.

**MAYENNE**. (Fr.) *Solanum esculentum*.

**MAYFLOWER**, *Epigæa repens*. — **WEST INDIAN**, *Dalbergia Brownæ*, and *Ecataphyllum Brownæ*.

**MAY-LILY**, *Convallaria majalis*.

**MAYNA** (including *Lindackeria*). A genus of *Flacourtiaceæ*, distributed over Mexico, New Grenada, Guiana, and Brazil, and represented by middle-sized trees, with ovate or oblong coriaceous leaves, polygamous flowers arranged in racemes, and a round fruit, covered with numerous prickles and resembling very much our common horse-chestnut in outward appearance. The sepals and petals are imbricated; the anthers linear, and opening by two slits; the styles completely united; and in the female flowers there appear to be never more than three placentas. From being imperfectly known, and on account of its stipules, the genus had been placed near *Magnoliaceæ* until united with *Lindackeria*, and placed amongst *Bixacæ* by Benthams. [B. S.]

**MAYPOLE** of Jamaica. *Spathalia simplicis*.

**MAYS DEL MONTE**. The Peruvian name of *Ombrophytum*.

**MAYTENUIS**. A genus of *Celastraceæ*, consisting of South American evergreen shrubs or small trees, with alternate coriaceous serrate leaves, and small flowers solitary or clustered in their axils. The fruit contains but a single seed, as in *Myginda*, from which this genus differs chiefly in its alternate, not opposite leaves. There have been near fifty species described, but probably not so many are really distinct. The arborescent species have a very hard wood, and the leaves of the commonest Peruvian species, although astringent, are said to be greedily devoured by cattle.

**MAY-WEED**, *Anthemis* or *Marisa Cotula*; also *Pyrethrum Parthenium*. — **STINKING**, *Matriaria Chamomilla*.

**MAYWORT**, *Gallium cruciatum*.

**MAZI**. The Turkish name for *Galla*.

**MAZUS**. A genus of *Scrophulariaceæ*

nearly allied to *Mimulus*, of which it has the corolla stamens and capsule; but the calyx is broadly campanulate and deeply five-lobed. It consists of three or four South Asiatic or Australian herbs, either low branching annuals or perennial through their creeping runners. They are uninteresting weeds, the most common of them, *M. rugosus*, very widely spread over tropical Asia.

MAZZARD. The wild *Cerasus avium*.

MEADOW BEAUTY. An American name for *Rhexia*.

MEAD-SWEET, MEADWORT, or MEADOW-SWEET. *Spiraea Ulnaria*.

MEAL-BERRY. *Arctostaphylos uva ursi*.

MEALY-TREE. *Viburnum Lantana*.

MECHOACAN ROOT. *Batatas Jalapa*.

MECONELLA. A curious little *Papaveraceus* plant, proposed by Nuttall as a genus, but united by Bentham and Hooker with *Pulsatilla*, from which it is usually distinguished by the fewer stamens. Torrey and Gray place it between *Platystemon* and *Hypsocyon*, but its connection with the latter is very slight. Its characteristic marks are three sepals, five or six petals, four to six stamens with membranaceous filaments dilated upwards, and short anthers, three rarely four linear sessile stigmas, and a slender pod shaped three rarely four-celled capsule, containing numerous smooth shining seeds. *M. oregana* is a dwarf smooth annual, with a rosulate tuft of spatulate root leaves, dichotomously forked slender stems bearing linear leaves, and very small ochroleucous flowers on filiform axillary peduncles. As its name implies, it is a native of North-west America. [T. M.]

MECONOPSIS. An herbaceous perennial belonging to the *Papaveraceae*, distinguished from *Papaver* by having a short style and five to six free stigmas. *M. cambrica*, the Welsh Poppy, a native of Wales, Devonshire, Somerset, York, Westmoreland, and Ireland, is a pretty plant about a foot high, with bright green pinnate hairy leaves, slender stems, and large terminal remarkably fugacious flowers which droop while in bud, and are of a delicate sulphur-yellow colour. [C. A. J.]

MÉDAILLE DE JUDAS. (Fr.) *Lunaria biennis*.

MEDEOLA. A genus of *Trilliaceae*, containing a North American herb, *M. virginica*, which has a white rhizome tasting like cucumber, from which the plant derives its local name of Indian Cucumber-root. It has an erect simple stem with a whorl of obovate-lanceolate sessile leaves, and a second whorl of smaller ones near the top, subtending a sessile umbel of small greenish-yellow flowers. [J. T. S.]

MEDER-DEUR. *Eigelia abyssinica*.

MEDICAGO. The Medick genus: one of the *Papilionaceae*, and distinguished by its more or less spirally twisted legume. The

more important species are the following:—

*M. sativa*, the Purple Medick, or Lucerne. This, though found apparently wild on the borders of fields, has doubtless escaped from cultivation; it is distinguished by its purple flowers and upright growth. Its herbage is green and succulent, and has the advantage of being early, on which account it has been highly extolled as an agricultural plant. It yields two rather abundant crops of green food in the year, of a quality highly relished by horses and cattle. *M. lupulina*, the Black Medick, or Nonsuch, is at first sight so much like the yellow trefoils as to be generally known by farmers as the Hop trefoil, or Hop; it is, however, distinguished by its naked black legume. It is used in farming to mix with grasses and clovers for artificial or shifting pastures, in which it often assumes a luxuriance of growth well befitting it for this purpose. *M. maculata*, remarkable for its spirally-coiled prickly legumes, has, from the quantity of herbage which it grows, been recommended for cultivation as a green fodder plant; but it is scarcely equal to the former, while in hay the long prickles to its seed-vessels render it very objectionable. [J. B.]

MEDICIA *elegans* is a name given by Gardner to a very handsome Hongkong twiner, which has since proved to be a species of *Celastrum*.

MÉDICINIER. (Fr.) *Jatropha*.

MEDICK. *Medicago*.

MEDINILLA. Between two and three dozen species of this genus of *Meletemataceae* have been described, all from the islands of the Indian Ocean. They are shrubby plants, generally quite smooth, with opposite or whorled entire fleshy leaves, the primary nerves of which are strongly marked and often coloured, and having panicles of rose or white flowers, the calices and stalks of which are nearly always reddish. The principal characters of the genus reside in the limb of the calyx being entire or at most obsoletely lobed, and in the stamens, of which there are eight or ten (double the number of the floral envelopes), having basal-fixed generally incurved anthers with two lobes or spurs at the bottom in front and one behind. *M. magnifica* is a truly magnificent plant. [A. S.]

MEDIOORE. Intermediate between large and small.

MEDIAR. *Mespilus germanica*. The Mediar of Surinam is said to be a spotaecious plant. —, JAPAN. *Eriobotrya japonica*.

MEDORA. A genus of *Liliaceae*, of the tribe *Asperagineae*, founded on the *Smilacina fusca* of Nepal. It has a creeping rhizome, an erect simple stem, stalked cordate-ovate acuminate leaves, and terminal dichotomous many-flowered peduncles of long-stalked flowers, nearly racemose on the ultimate divisions. The perianth is

deciduous, of six violet leaves with a green spot above the middle. [J. T. S.]

**MEDRINAQUE.** A coarse fibre from the Philippines, obtained from the Sago palm, and used chiefly for stiffening dress linings, &c.

**MEDULLA** (adj. **MEDULLARY**). The pith; that central column of cellular matter over which the wood is formed in Exogens.

**MEDULLARY RAYS.** The cellular plates or processes which connect the pith of Exogens with the bark, constituting the 'silver grain' of their wood.

**MEDULLARY SHEATH.** A thin stratum of spiral vessels formed immediately over the pith.

**MEDULLOSE.** Having the texture of pith.

**MEDUSA'S HEAD.** *Euphorbia Caput Medusæ*; also *Cirrhopetalum Medusæ*.

**MEGACARPEA.** A genus of *Cruciferae* of the tribe *Thlaspidæ*, containing one or two perennial herbs from the deserts of Central Asia. They have deeply pinnatifid and cut leaves covered with white woolly hairs, and terminal racemes of small purplish flowers. The pouch is very large and flat, compressed contrary to the partition, the valves orbicular, each with one seed. *M. polyandra*, the *Rongeo* of Kumaon, is remarkable in the cruciferous order for its numerous stamens, from ten to sixteen in number. [J. T. S.]

**MEGACLINIUM.** A small genus of orchids of tropical Western Africa, remarkable for the curious flattened sword-shaped leafy rachis or flower-stalk upon which the no less curious little flowers are seated in a straight row along the middle on both sides. It is closely related to *Bolbophyllum*, with which, indeed, some orchidologists unite it, the chief distinctions being that in *Megaclinium* the posterior sepal is much larger than the other two, and united to them at the base, the lip is loosely articulated with the base of the column, and the four pollen-masses are all of the same size. The flowers are of a greenish or yellowish brown, spotted more or less with purple, and have a fancied resemblance to little frogs or toads, whence one species has been named *M. Bufo*. The four or five known species are all epiphytes, and have creeping rhizomes, bearing pseudobulbs furnished with leathery veinless leaves, and radical flower-racemes. [A. S.]

**MEGALOS.** In Greek compounds—large.

**MEGASEA.** *Saxifraga crassifolia*, *S. cordifolia*, and their allies.

**MEIA.** A Tahiti name for *Musa paradisiaca*.

**MEION.** Less; prefixed to the name of an organ, indicates that it is something less than some other organ understood. Thus *metogyrius* means but little rolled inwards; and *meiostenonous* is said of a plant

whose stamens are fewer in number than the petals.

**MEISSNERIA.** A Brazilian genus of *Melastomaceæ*, comprising about half a dozen species of small erect hairy herbs, with nearly simple or but slightly branched stems, small mostly sessile leaves, and small axillary bunches of reddish or purplish flowers. These latter have a calyx with a free campanulate tube and four lobes about as long as the tube itself; four petals; eight stamens, of which only four are fertile and have beaked anthers opening by a broad pore at their ends; and a filiform style ending in a punctiform stigma. [A. S.]

**MELALEUCA.** This name, derived from the Greek *melas*, black, and *leukos*, white, is stated to have been applied to a genus of *Myrtaceæ*, in consequence of the trunk of one of the species being black, and the branches white. The genus consists of trees or shrubs, natives of Australia and the islands of the Indian Ocean, with alternate or opposite flat or cylindrical leaves, and yellowish purplish or crimson flowers, sessile in spikes or heads. The calyx tube is hemispherical; there are five sepals and petals; alternate with the latter are five parcels of stamens; and the capsule is three-celled, united with and enclosed in the thickened tube of the calyx, which also adheres to the branch supporting it.

These plants are all of them aromatic from the presence of a volatile oil. The best known among them on this account is *M. minor* or *M. Cajuputi*, the leaves of which, after fermentation, are distilled for the purpose of yielding the oil known as *Cajuput* or *Cajeput* oil, which is green, and has a powerful aromatic odour. It is valuable as an antispasmodic and stimulant, and in 1831 was recommended as a remedy for cholera, in consequence of which the price of the oil was enormously increased, and its quality proportionately deteriorated. It is more than doubtful if, even in the pure state, it possesses any advantage over any oil of a similar nature. The leaves of this tree are used in China as a tonic in the form of decoction, where also the bark is made use of in the construction of boats and roofs for houses. Numerous species are grown as evergreen greenhouse plants in this country, on account of the simplicity of their foliage and the splendour of their clustered flowers. [M. T. M.]

**MELANPODIUM.** A genus of *Compositæ* of the tribe *Heliantheæ*, consisting of coarse dichotomous annual or perennial herbs, with opposite leaves, and rather small flower-heads growing singly from the forks of the stem. The involucre has five outer spreading herbaceous bracts, and five to ten inner ones enclosing as many florets of the ray, which are ligulate, female, and usually yellow. The receptacle is convex or conical, scaly, with numerous small tubular male florets. The achenes of the ray are entirely enclosed in the persistent and usually hardened inner bracts

of the involucre, and are usually crowned by a small cup-shaped pappus, often bearing one to three bristles. There are nearly twenty species, natives of tropical America, one of them found also in the Philippine Islands, but probably introduced with other American weeds.

**MELAMPYRUM.** The Cow-wheat, a genus of annuials belonging to the *Scrophulariaceae*, having erect slender stems, narrow opposite leaves, and axillary or spiked flowers which are two-lipped, the upper lip being compressed and turned back at the margin, the lower three-cleft. The meaning of the systematic name, 'black wheat,' bears reference to an ancient belief that the seeds, when mixed with grains of wheat and ground into flour, tended to make the bread black. There are four British species: *M. pratense*, the most frequent, which inhabits dry woods; *M. sylvaticum*, a much less common species, found in the north; *M. cristatum*, which grows principally in the eastern counties; and *M. arvense*, not unfrequent in the Isle of Wight, where it is a conspicuous object in the corn fields, with its large oblong spikes of flowers variegated with yellow, green, and crimson. French, *Mélampyre*; German, *Wachtelweizen*. [C. A. J.]

**MELANCHOLY GENTLEMAN.** *Hesperis tristis*.

**MELANDRUM.** By a few authors the genus *Lychnis* is divided into several, and one of these is named *Melandrum*, and embraces all those species which have inflated calices, and capsules opening by ten instead of five teeth. There are about a dozen species having these characters, all of them Alpine or northern, and three natives of Britain: these are, *L. vespertina*, *diurna*, and *alpina*. [A. A. B.]

**MELANISM.** A disease producing blackness.

**MELANOGASTER.** A genus of underground *Fungi*, belonging to the natural order *Hypogaei*, distinguished by a tough skin more or less overrun externally with branched fibres, and within containing sinuous moist cavities, whose walls support smooth naked spores. Most of the species have a disagreeable smell, but *M. variegatus*, which is less offensive, is used in the west of England as a substitute for truffles, under the name of Red Truffle. It has, however, none of the delicate aroma of the real truffle, and probably has little merit beyond giving a dark colour to the sauce of which it forms a part. We are not aware that the genus has been found out of Europe. [M. J. B.]

**MELANORRHOEA.** Two very large East Indian trees constitute this genus of *Anacardiaceae*, which derives its name from the Greek words *melanos*, black, and *rheo*, to flow, in consequence of the juice which flows from their trunks turning black upon exposure to the air. They grow upwards of a hundred feet high, and have broad spreading heads bearing large simple

entire leaves of a thick texture, and axillary panicles of perfect flowers. These have five sepals cohering so as to form a kind of cup, five overlapping petals, and numerous stamens. The fruit is surrounded by the enlarged petals spread out in a star-like manner.

*M. usitatissima* is common in forests from Tenasserim and Pegu to Manipur in Sylhet. It is called Theet-see in the former, and Kheu in the latter country; and its dark-coloured wood, on account of its excessive hardness and great weight, is known as the Lignum Vitæ of Pegu—so heavy, indeed, is it, that anchors for native boats are made of it. The most valuable and extensively used product of the tree, however, is the black varnish which it yields. This is obtained by the process of tapping, short joints of bamboo, closed at the bottom end, being thrust into holes made in the trunk and left for about two days, when they become full of a whitish thick juice which turns black when exposed to the air, and requires to be kept under water in order to preserve it. All kinds of domestic utensils and furniture are lacquered with this juice, which is laid on thin and slowly dried, the change from white to black being, according to Sir D. Brewster, attributable to its losing its organised structure and becoming homogeneous, and then transmitting the sun's rays, which, in its previously organised state, it dispersed. Like other varnishes derived from the same natural order, it is apt to cause erysipelatous swellings if applied to the skin. [A. S.]

**MELANOSELINUM.** A genus of umbellifers, distinguished by each half of the fruit having five narrow primary ribs and three secondary, the two outermost of the latter in the form of broad wings with a saw-like edge. The only species is *M. decipiens*, a shrub with a round simple stem, bare below, the leaves in three principal divisions, the flowers white. [G. D.]

**MELANOSINAPIS.** One of the sections of *Sinapis* sometimes separated, and characterised by its small short not beaked style, and terete or sub-tetragonous pods. It embraces the black mustard, *Sinapis nigra*, and a few allied species. [A. S.]

**MELANOSPERMÆ.** One of the three great divisions of *Algae*, characterised by their dark olivaceous spores. The plants themselves are of a light or dark olive, and the fruit is either external in diffuse or definite patches, or contained in distinct cysts sunk in the frond. The endochrome of the spore-cases is, for the most part, ultimately divided into several spores multiples of two. Impregnation is effected by means of minute spermatozooids moving by means of cilia, and produced in distinct antheridia. Occasionally there are two kinds of spores, both reproductive. The frond is either compact and cellular, or formed of jointed filaments. This division contains many of the largest and most important *Algae*, especially the large brown seaweeds which seem in all countries to

form the extremest limit of seaweed growth. The peculiarities of most of the natural orders, as *Fucaceae*, *Laminariaceae*, *Chordaceae*, and *Ectocarpaceae*, have already been particularised, as well as the several uses to which the species have been applied. In the latter order we have minute filamentous *Algae*, which form a strange contrast to the gigantic *Lessonia*, *D'Urvillea*, &c., or even to our own *Laminaria*. In some of the lower species there is a departure from the main type, and the spores are replaced by zoospores. [M. J. B.]

**MELANOXYLON.** A large timber tree called *Braúna* by the Brazilians and *M. Braúna* by botanists, is the sole representative of this genus of leguminous plants. It has large pinnate leaves, covered with rust-coloured down underneath, and bears branched racemes of yellow flowers which are likewise clothed with rusty down. The pods are flat and sickle-shaped, and contain several seeds. *Braúna* timber is of a very dark reddish-brown colour, and of excellent quality, being both hard and durable. It is employed in Brazil in the construction of sugar-mills, particularly for making the heavy rollers for crushing the canes. A reddish-brown colouring matter is also obtained from both the wood and the bark, and is used by the Brazilians for dyeing cotton cloth of various shades from light-brown to nearly black. [A. S.]

**MELANTHACEÆ.** (*Colchicaceae*, *Veratraceae*, *Melanths*.) A natural order of hypogynous monocotyledons, belonging to Lindley's illal alliance of Endogens. Herbs with bulbs, corms, or fasciculated roots, and white green or purple flowers. Perianth petaloid, in six pieces, which are sometimes slightly coherent, usually involute in aestivation; stamens six, with the anthers extrorse; ovary three-celled, the ovules numerous, the style three-parted, and the stigmas three, undivided. Fruit a three-celled capsule, with septicidal or loculicidal dehiscence; seeds with a membranous spermoderm; albumen dense, fleshy; embryo very minute. Natives of various parts of the globe, but most abundant in northern countries. They are acrid, purgative, emetic, and sometimes narcotic in their qualities. *Asagras officinalis* yields *scabadiila* seeds, used in neuralgia. *Colchicum autumnale*, the meadow saffron, is prescribed in gout and rheumatism, its corms and ripe seeds being used. There are upwards of thirty genera, and above a hundred and thirty species. Examples: *Colchicum*, *Melanthium*, *Uvularia*, *Veratrum*. [J. H. B.]

**MELANTHERA.** A genus of rough, branching, somewhat shrubby weeds of the composite family, found in the Southern United States, and southwards to Ecuador. They belong to the *Helianthem*, and differ from their near allies in the absence of strap-shaped ray florets, all the florets being tubular and perfect, and in the pappus, which consists of a few rigid bristles. The flowers are white, and the anthers black: whence the generic name. [A. A. B.]

**MELANTHIUM.** A genus of Cape *Melanthaceae*, consisting of bulbous herbs, with linear or lanceolate leaves sheathing at the base, and spicate flowers, which have a white yellow or pinkish perianth of six deciduous leaves, which are narrowed into claws and either hooded or bisaccate at the base. They have six stamens inserted on the perianth. [J. T. S.]

**MELANZANE.** (Fr.) *Solanum esculentum*.

**MELARANCIO.** An Italian name for the Orange-tree.

**MELA-ROSA, or MELLA-ROSA.** A variety of *Citrus Linnæa*.

**MELAS.** In Greek compounds = black without the mixture of any other colour.

**MELASTOMACEÆ.** (*Melastomæ*, *Menecylaceae*, *Mouririaceae*, *Melastomadae*.) A natural order of calycifloral dicotyledons belonging to Lindley's myrtal alliance of epigynous Exogens. Trees, herbs, or shrubs, with opposite ribbed leaves, and showy flowers. Calyx with four five or six divisions, sometimes united and separating from the tube like a lid; petals equal to the calyx, perigynous, the aestivation twisted; stamens alternate with the petals, usually with intermediate sterile ones; the anthers long, often beaked, two-celled, dehiscent by two terminal pores or longitudinally; ovary more or less adherent to the calyx; ovules usually indefinite; style one; stigma simple, either capitate or minute. Fruit many-celled, either capsular with loculicidal dehiscence, or succulent combined with the calyx and indehiscent. Seeds minute. They are found chiefly in warm climates. Many are natives of America and India. There are no unwholesome plants in the order, and the succulent fruit of several is edible. There are 165 genera, and about 2,000 species. Examples: *Melastoma*, *Lasiandra*, *Rhexia*, *Miconia*, *Charianthus*, *Menecylon*. [J. H. B.]

**MELASTOMA.** This genus gives its name to the order *Melastomaceae*. It contains a considerable number of species, distributed over tropical Asia and the islands of the Indian and Pacific Oceans, extending to as far south as Moreton Bay. The plants are small shrubs covered with close-pressed hairs; and have three, five, or seven-nerved leaves, and large violet purple pale rose or white flowers, mostly in fascicles at the summit of the branches. Their floral envelopes are generally in fives; the calyx with a campanulate tube and acute deciduous teeth nearly as long as itself, and smaller teeth between them; the petals unequal-sided; the stamens ten in number, dissimilar in size, shape, and colour, five being large and violet, and five small and yellow, the anthers of the former having a downward arcuate prolongation of the connective generally ending in two spurs, while those of the latter have the cells seated immediately upon the filament. The ovary is usually five-celled. [A. S.]

MELIÆZÆ. (Fr.) *Larix europæa*.

**MELHANIA.** A genus of *Sierculiaceæ* of the tribe *Dombeyææ*, characterised by having three bracteoles persistent at the base of the calyx, and by the anthers being always solitary between each two barren lobes of the staminal cup. It consists of about sixteen species, natives of Africa or of tropical or subtropical Asia and Australia. They are all softly tomentose herbs or undershrubs, with entire or toothed alternate leaves, and axillary peduncles bearing one or very few flowers. The bracteoles, either broadly cordate lanceolate or linear, are often longer than the calyx, and the petals scarcely spread open. These plants, therefore, with the aspect of some *Malvaceæ*, or almost that of *Hermannia*, are of little interest except to the systematic botanist.

**MELIACEÆ.** (*Melia*, *Meliada*.) A natural order of dicotyledons, belonging to Lindley's Rural alliance of hypogynous Exogens. Trees or shrubs with alternate exstipulate simple or compound leaves. Sepals four to five, imbricated; petals four to five, hypogynous, with a valvate or imbricated aestivation; stamens equalling the petals, or two, three, or four times as many; the filaments combined in a long tube; the anthers sessile within the orifice of the tube; disk often large and cup-shaped; ovary single, one-celled, the cells often equal in number to the petals; ovules one to two in each cell; style one; stigma distinct or united. Fruit baccate, drupaceous, or capsular, many-celled or by abortion one-celled; seeds not winged. They are chiefly found in the tropical parts of America and Asia, and possess bitter, tonic, and astringent qualities. *Melia Azadirachta* is used in India as a febrifuge, and its fruit yields an oil which is employed for domestic purposes, and as an antispasmodic. The root of *Melia Azedarach* is bitter, and used as a vermifuge. Oils are procured also from species of *Trichilia* and *Carapa*. There are upwards of forty genera, including *Melia*, *Turraæ*, *Trichilia*, and *Carapa*, and a hundred and eighty species. [J. H. B.]

**MELIA.** A genus of *Meliaceæ*, conferring its name upon the order to which it belongs, and consisting of trees and shrubs inhabiting the tropics. They have alternate pinnate or bipinnate leaves, and paniculate flowers. The calyx is five-cleft; the corolla has five linear petals; there are ten stamens; and an almost fleshy five-celled drupe, each cell containing one, seldom two seeds. *M. Azedarach*, vulgarly known as the Pride of India, False Sycamore, Holy-tree, Arbre à Chapellet, Bead-tree, or Hill Margosa, is widely diffused over the globe, having been carried to America, Africa, and different parts of Southern Europe. It is from thirty to fifty feet high, with bipinnate leaves, and large bunches of lilac flowers emitting an agreeable perfume. In Southern France and Spain the tree thrives well in the open air, and is planted in avenues. The Arabic

name, *Azedarach*, implies a poisonous plant, and the fruit is generally considered so. The root is bitter and nauseous, and used in North America as an anthelmintic. The tree is supposed to possess febrifugal properties, and a decoction of the leaves is used as a remedy for hysteria. From another Indian species, *M. Azadirachta*, the Neem-tree or Margosa, a kind of toddy, which the Hindoos consider a stomachic, is obtained by tapping; and from the fruit an oil is extracted fit for burning and other domestic purposes. [B. S.]

**MELIANTHUS.** [A genus of *Sapindaceæ*, consisting of small trees of the Cape of Good Hope, one species being naturalised in Nepal, and on the Neilgherry hills.] The leaves are glaucous, unequally pinnate, the leaflets unequal and extended along the side of the stalk; the stipules are usually combined within the axil of the leaf. The flowers are in axillary or terminal clusters, the lower ones sometimes imperfect; while the upper ones have a large calyx generally of a purple colour, its five segments unequal in size and form: the lowest very short, bulging below, hooded above, concealing a gland, which is itself girt round by a separate membrane; the others lance-shaped and flat, the two upper ones largest. The five petals are shorter than the sepals, strap-shaped; the four lower ones bent downwards, hairy in the middle, where they are united one to another, but elsewhere detached; the uppermost one when present very small, separate from the rest, placed between the two upper sepals, but usually absent. Stamens four, the two upper detached, the two lower united together at the base; ovary and stigma four-lobed; fruit bladder-like, four-celled, and winged. Two or three species from the Cape are grown in greenhouses in this country, and will even grow out of doors if protected in winter. They are singular in appearance, even when the flowers are not produced. The flowers, which rarely appear in this country, are full of honey, whence the name of the genus. [M. T. M.]

**MELICA.** A genus of grasses belonging to the tribe *Festuceæ*. The inflorescence of the different species consists either of open panicles or dense racemes. The glumes are nearly equal, larger than the pales, one to two-flowered, with the rudiments of one to two additional imperfect flowers. The pales become hardened on the seed. The species have a wide range over the globe, but are mostly natives of temperate climates. Two are British, namely, *M. uniflora* and *M. nutans*. They are handsome grasses, but of no agricultural value, though the latter is one which grows well under trees, and consequently is of some importance in that respect. [D. M.]

**MELICOCOA.** A genus of *Sapindaceæ*, now restricted to two American species, trees of considerable size, and natives of the northern part of South America. Their leaves are abruptly pinnate and without

stipules, and their small whitish flowers are produced in divided racemes at the ends of the branches. *M. bijuga*, the Genip tree, though originally a native of Gulana and New Grenada, is now plentifully found in several of the West India Islands, especially in Jamaica, where it has become naturalised and grows commonly in the lowlands, attaining the height of forty or fifty feet, with a trunk four or five feet in circumference, yielding a hard and heavy timber. It produces numerous green egg-shaped fruits an inch or more in length, possessing an agreeable vinous and somewhat aromatic flavour: the generic name being derived from the Greek words *mell*, honey, and *coccus*, a berry, in allusion to the qualities of the fruit. [A. S.]

**MELICOPE.** A genus of New Zealand shrubs, belonging to the family *Rutacee*. The leaves are ternate; the flowers greenish-white; calyx four-parted, persistent; petals four, spreading; stamens eight, with awl-shaped filaments; ovary four-lobed, inserted on a glandular disk, each lobe with two ovules. Fruit divided into four carpels, each containing a single seed suspended by a thread. [M. T. M.]

**MELICYTUS.** A New Zealand genus of *Violacee*, belonging to the equal-petaled division of the order. The four species all form large woody shrubs or small trees, with long smooth serrated short-stalked leaves, and little bundles of small flowers on the branches, each flower-stalk having one or more bracts. The flowers are usually of separate sexes, and borne on distinct plants. *M. ramiflorus* is the Mahoe of the New Zealanders, which must not be confounded with the Mahoe of the West Indies. It is a tree growing sometimes as high as forty or fifty feet, with a trunk about four feet in circumference covered with white bark, producing a heavy wood of inferior quality. The berries are eaten by the natives. [A. S.]

**MÉLIER À TROIS NERVURES.** (Fr.) *Blakea trinervia*.

**MELIGA.** An Italian name for Millet or Durra.

**MÉLILOT.** *Melilotus officinalis*.

**MÉLILOT DE SIBÉRIE.** (Fr.) *Melilotus alba*.

**MELILOTUS.** A genus of leguminous plants containing about thirty species, the majority belonging to Southern and Central Europe and Western Asia. They are herbaceous plants with trifoliate leaves, having the stipules adhering to their foot-stalks, and each of the three leaflets on a separate stalk; and their small yellow or white flowers are disposed in long-stalked loose racemes growing from the bases of the leaves. The flowers are characterised by the calyx being five-toothed, by the corolla having a blunt keel, and falling away after fading, and by the upper one of the ten stamens being free. The pods,

which are straight, thick, and short, contain one or few seeds.

*M. officinalis*, the Common or Yellow Melilot, is widely spread through Europe and Russian Asia. It is an annual or biennial of erect habit, from two to four feet high, having spreading branches and distant long-stalked leaves with bristle-like stipules. The long loose racemes of yellow flowers produce small oval pods, marked with irregularly netted veins. When dried the Melilot acquires a peculiar odour, due to the presence of *coumarine*, a principle which exists likewise in the Tonka bean and the vernal grass, the latter when mixed with hay contributing largely to its fragrance. Its flowers are sold by the herbalists as Balsam flowers. In Switzerland, *M. caruleus* is called Zieger Kraut, i.e. curd herb, and is employed for giving the odour and flavour to the peculiar cheese called Schabzieger or Chappalger, the dried flowers being reduced to powder and worked up into a paste with the curd. [A. S.]

*M. officinalis* is an annual under ordinary circumstances, but 'if cut continually and not allowed to flower, it will last several years.' *M. alba* has been grown under the names of Calul and Bokhara or Buchara Clover. As a forage plant 'it has been found too watery when young, and too sticky when old.' But besides this, we have found that the aromatic flavouring principle is too powerful to make it advisable to use this plant by itself. There is, however, one use to which it may be well applied—that of putting an occasional layer of it sandwich-wise with less highly-flavoured fodder, or with hay that has lost some of its savour by wet; here its aroma, which is so much like that of the sweet vernal grass, to which the flavour of meadow hay is mainly due, might be productive of benefit in rendering what would otherwise be insipid, more spicy and palatable. This White Melilot is also an excellent bee plant. [J. B.]

**MÉLINET.** (Fr.) *Cerintho aspera*.

**MELIOLA.** A genus of *Fungi* allied to *Sphæria*, and analogous to *Erysiphe*, which it replaces in tropical or subtropical countries. The species form black felt-like patches on leaves, and bear conspicuous perithecia filled with asci containing a few large articulated dark spores. [M. J. B.]
